Figure L.124 Hendrik Antoon Lorentz (1853–1928). (Courtesy Collection Museum Boerhaave, Leiden. Long-term use from the “Haags Historisch Museum,” Den Haag, the Netherlands.)

Lorentz constant (L_{t_e})

[solid-state, thermodynamics] Ratio of thermal and electrical conductivity, specifically for metals: L_{t_e} , where $L_{t_e} = \kappa_{\text{cond}} / \sigma_e T = \pi^2 \kappa_{\text{cond}}^2 / 3e^2$ is the **THERMAL CONDUCTIVITY**, κ_e the electrical conductivity, σ_e temperature, T the electron charge. This is also known as the **WIEDEMANN–FRANZ RATIO**.

Lorentz contraction

[atomic] In special relativistic terms the atomic events are taking place in reference frames that travel with respect to each other and when the Lorentz transform is applied the dimensions as well as time become reduced as seen from a nonparallel coordinate system (see **LORENTZ–EINSTEIN EQUATIONS**).

Lorentz equations

[atomic, nuclear] See **LORENTZ–EINSTEIN EQUATIONS**.

Lorentz force (-law)

[electromagnetism, mechanics] The electromagnetic force on a charged **PARTICLE** under the influence of an external **MAGNETIC FIELD** ($c = 2.998 \times 10^8$ m/s) and nearby **ELECTRIC CHARGES**, is defined as $\vec{F}$, with $\vec{F} = q\vec{E} + q\vec{v} \times \vec{B}$ the electric charge of the body in **MOTION** in an electric field: q , where $\vec{E} = (Q/4\pi\epsilon_0 r^2)\vec{r}$ represents the total charge at **DISTANCE** Q from the moving charge, and r the **DIELECTRIC** permittivity of free space; traveling at velocity $\epsilon_0 = 8.85 \times 10^{-12}$ C²Nm⁻² while exposed to a magnetic field. Lorentz force, the force ($\vec{v}$) acting on an electric charge ($\vec{F}$) in motion with velocity q when exposed to an electromagnetic field (composed of a synchronized electric field $\vec{v}$ and magnetic field $\vec{E}$). The force as derived by Hendrik Lorentz (1853–1928) is described by $\vec{B}$.

Lorentz transformation

[atomic, computational, nuclear] Coordinate transformation described by HENDRIK ANTOON LORENTZ (1853–1928) describing the transformation from one reference frame (I) to another: S , defined for the respective coordinates of each system (S) as x_i , where $\bar{x}'_{\zeta} = \Lambda_{\zeta\kappa} \bar{x}_{\kappa}$, with $\bar{x}_{\zeta} = (x_1, x_2, x_3, x_4) = (x, y, z, i_{CT})$ a transformation matrix with constants that are independent of the space-time CONTINUUM, implying a constant relativistic interval: $\Lambda_{\zeta\kappa}$. The determinant of the transformation matrix is unity: $\bar{x}'_{\zeta} \cdot \bar{x}'_{\zeta} = \bar{x}_{\zeta} \cdot \bar{x}_{\zeta}$. As a condition for preservation of the space-time coordinates the following condition applies: $\det[\Lambda_{\zeta\kappa}] = 1$ for both $\Lambda_{\zeta\kappa} = \text{Real}$ and $\zeta = 1.2.3$, as well as $\kappa = 1.2.3$ while $\Lambda_{4,4} = \text{Real}$ and $\Lambda_{4,\kappa} = \text{Imaginary}$.

Lorentz–Einstein equations

[computational, nuclear] Transformation equations used to convert one observer coordinate and time system to another system's when the systems are moving with respect to each other. For location the transform uses the relative velocity (v), giving $x' = \text{Const}(x - vt)$, where $t' = \text{Const}(t - (vx/c^2))$ is the speed of light and c .

Lorentz–FitzGerald contraction

[general] Concept originally introduced in 1892 by GEORGE FRANCIS FITZGERALD (1851–1901) and HENDRIK ANTOON LORENTZ (1853–1928) to dispute the results from the MICHELSON–MORLEY EXPERIMENT, which discounted the concept of ETHER (AETHER) in the propagation of ELECTROMAGNETIC RADIATION. The “contraction” describes the interaction of the (nonexisting) ether wind on objects propagating through the fictional medium and experiencing a compression, accounting for the balance in the INTERFEROMETER. Even though there is no such thing as ether, the Lorentz–FitzGerald contraction still remains part of mathematical expression of historical PHYSICS. The expression describes the fictional compression of the arm (with length $\text{Const} = 1/[1 - (v^2/c^2)]$) of the interferometer that is “aligned” with the ether-wind, expressed as L_{arm}' , where $L_{\text{arm}}' = L_{\text{arm}} \sqrt{1 - \beta_M^2}$, with $\beta_M = v/c$ the speed of the object, and v the speed of light.

Lorentzian electron oscillator model

[nuclear, optics, solid-state] Lorentz proposed an atomic electron attraction force that resembled Hook's law ($\vec{F} = q(\vec{E} + \vec{v} \times \vec{B})$), where the force $F = kx$ is proportional to a “spring constant” (F) times a translation (k), which in actuality resembles the DIPOLE attraction for an electron–ATOM interaction (Note: prior to the official discovery of the electron). Lorentz's work defined a damped spring WAVE EQUATION for an unknown (hypothetical at the time) PARTICLE with mass m and charge $m: e$, where $(d^2/dt^2)x(t) + 2\gamma(d/dt)x(t) + \omega^2 x(t) = (e/m)E(t)$ the oscillating electric field over time ($E(t) = E_0 \cos(\omega t)$), with ANGULAR FREQUENCY t with $\omega = 2\pi\nu$ the frequency. In this expression the factor γ is a dampening factor that is linked to atomic collisions and could not be defined by Lorentz at the time. This is very similar to the alternating wave propagation in a LRC-circuit: consisting of INDUCTOR (L), RESISTOR (R), and CAPACITOR (C). Also described as the Lorentz electron oscillator model.

Lorentzian line profile

[general, optics] Line width (full-width half maximum: γ) of electromagnetic emission around a center FREQUENCY ($\Delta\nu$) resulting from atomic transitions defined by a NORMAL DISTRIBUTION as ν_0 . Generally the linewidth is proportional to the lifetime of the excited ENERGY level.

Lorenz, Edward Norton (1917–2008)

[computational, geophysics] Mathematician and meteorologist from the United States. Lorenz introduced chaos theory in weather prediction, making the prediction PROBABILITY theory a balanced mechanism, with two “probability wings.” Atmospheric phenomena are generally nonlinear meaning that in case some

unusual weather event takes place in one location there must have been a precursor in a location (not necessarily the same) that instigated the meteorological changes. This concept is called the LORENZ BUTTERFLY (see Figure L.125).

Figure L.125 Edward Norton Lorenz (1917–2008).

Lorenz butterfly

[computational] In deterministic theory the concept of the correlation between two seemingly unrelated events in a nonlinear system as described by CHAOS THEORY. The concept coined by EDWARD NORTON LORENZ (1917–2008) was described as the contingency of the development of a hurricane in one location and the fact that a butterfly flapped its wings somewhere else earlier in time (hours–days–weeks) (see Figure L.126).

Figure L.126 Graphical representation of the Lorenz Butterfly interaction probability. (Courtesy Marc Kjerland, University of Illinois at Chicago, Chicago, Illinois.) The axis represent the “state-variable” in the format: 2572°C ; $x' = \sigma(y - x)$; and $y' = x(r - z) - y$. (Graph developed with MATLAB®/Octave code: <http://homepages.math.uic.edu/~kjerland/Lorenz/mylorenz.m>.)

Lorenz model

[computational] A mathematical model of the migration of AIR around the world in the ATMOSPHERE as defined by EDWARD NORTON LORENZ (1917–2008). This work resulted in a 12-variable computer weather model, drawing attention to the influence of presumed negligible events and conditions on the outcome of weather predictions.

Los Alamos National Laboratory

[atomic, nuclear] Government research facility created in 1943 in Los Alamos, New Mexico, in association with the MANHATTAN PROJECT and is operated by US Department of Energy under the National Nuclear Security Administration. The facility has evolved in a multidisciplinary research institute focusing on nuclear safety issues, specifically basic sciences on nuclear weapons as well as data collection and analysis with regard to national threats. The institute also provides technical solutions to ENERGY and health topics (see [Figure L.127](#)).

Figure L.127 Aerial photograph of the Los Alamos National Laboratory. (Courtesy of Los Alamos National Laboratory.)

Loss factor ($\Lambda_{\zeta,4}$ = Imaginary)

[fluid dynamics] Total loss in a system resulting from viscous flow, as well as entry, exit points, valves and bends. The loss is expressed as the “HEAD LOSS” (ζ) representing the loss in height that can be reached, as h_s , where $h_s = (\eta(\ell/d) + \sum \zeta)(v^2/2g)$, represents the frictional flow loss, with $\eta(\ell/d)(v^2/2g)$ the coefficient of FRICTION, η the length of the device, ℓ the FLOW diameter, d the average flow velocity, and v the GRAVITATIONAL ACCELERATION; the remaining losses from structure are g , where $\sum \zeta(v^2/2g)$ represents the sum of the loss factor $\sum \zeta$, while for a butterfly valve ζ , $\zeta = t/d$ is time. The loss factor can be defined for certain specific objects, for instance ball valve, butterfly valve, stop cock, disk valve, and NEEDLE VALVE to name but a few. Loss factors can generally be found in tables which list the experimentally determined coefficients.

Loss of head

[fluid dynamics] See HEAD LOSS.

Lost work rate

[thermodynamics] loss of work in irreversible process as a function of time.

Loudness

[general] The PERCEPTION of an observer with respect to an intensity, primarily pertaining to SOUND. The sensation is a function of wavelength (i.e., frequency) of the pressure WAVE (*also* FREQUENCY SPECTRUM), and duration. This is however not identical to the PAIN THRESHOLD FOR SOUND, also frequency dependent (see Figure L.128).

Figure L.128 Loudness diagram, expressed in decibel (dB), according to ISO 226:2003 standards and with respect to the original 40-phon standard in blue. (Courtesy of Peter J. Skirrow.)

Loudspeaker

[acoustics, electronics, fluid dynamics, mechanics] Mechanical device used to convert electrical alternating current into SOUND with the same OSCILLATION frequency, rather FREQUENCY SPECTRUM (*also see SPEAKER*) (see [Figure L.129](#)).

Figure L.129 (a) Diagram of a woofer loudspeaker and (b) components of base loudspeaker illustrated in (a). (Courtesy of JL Audio.)

Lowest energy principle

[thermodynamics] In a system with various states and values for ENTROPY, number of constituents and boundary conditions (e.g., pressure, volume, temperature, etc.), there is one stable EQUILIBRIUM STATE that has the lowest ENERGY.

Lowest energy states

[thermodynamics] For a system with a certain number of constituents, at a specific volume the lowest ENERGY state will be defined by zero temperature and zero entropy.

Low-level light therapy (LLLT)

[biomedical, chemical, optics, thermodynamics] Stimulation or modification of biological effects and processes by means of light. The modifications can be on a cellular level, increasing the METABOLISM, or ranges to the psychological impact of light “winter blues.” Also known as low-level laser therapy, and fall within the broader definition of LASER BIOSTIMULATION. Biostimulation: It has been demonstrated that cells irradiated by visible, ULTRAVIOLET and near-infrared light receiving less than optimal nutrient conditions grow just as well or better than control cells. In these research protocols the control cells are not

exposed to light and are maintained under optimal nutrient conditions. The LLLT has direct implications for at least the following different CELL types: keratinocytes, fibroblasts, and macrophages/mast cells. As part of the photobiostimulation process basement membrane proteins, INTEGRINS, and calcium-binding proteins were shown to exhibit an increase in the number of receptors for a chemical or drug. As a result the cells are more reactive to the effects of the agent. Additionally, gene expression analysis revealed that many genes were upgraded in their response, making them more reactive to the effects of the agent under irradiation by light. Additionally, certain families of genes involved in MUSCLE differentiation have been shown to experience an altered expression under the influence of light. The upregulation of these types of genes support the theory that light treatment is a valid technique to use for biostimulation. Red to near-infrared irradiation can increase DNA synthesis and cellular ADHESION. Additionally, melatonin has been shown to act as a modulator of cell adhesion upon illumination. Melatonin acts as a free radical scavenger and an antioxidant, but is not involved in redox reactions. It was found that melatonin negatively affected cell adhesion under irradiation with light. Because levels of melatonin differ significantly between day and night in humans, the study suggests the importance of using low-level light therapy during daytime hours, when physiological levels of melatonin are lowest in the HUMAN BODY. Different cell lines and cell culture systems have been used and a broad range of wavelengths have been investigated for their potential stimulatory effects. The majority of research since the 1980s, however, has focused on red, far red, and near INFRARED radiation. One of the first glimpses into the healing effects of red radiation came from Mike Boulton (late twentieth century–) and John Marshall (late twentieth century–), who investigated He–Ne laser stimulation of cultured human fibroblasts. They found that both the growth rate of these cells was increased with exposure to low-level laser light and that attachment of the cells to a substrate was enhanced. The birth of photobiomodulation in the late 1970s and early 1980s led to research concerning the molecular mechanisms of light's stimulatory effects with significant contributions by the scientist Martin J. C. van Gemert from the Netherlands (mid twentieth century) and Ashley J. Welch (–2009) from the United States. Specific applications in this area relate to the treatment and removal of port-wine stains (nevus flammeus). In 1960, Solon A. Gordon (1916–1973) and Kenneth Surrey (mid twentieth century–) discovered that light from the red and far-red regions of the visible light spectrum encouraged oxidative phosphorylation in the mitochondria. The mitochondrion is the organelle of the cell responsible for ENERGY production through aerobic RESPIRATION. The mitochondria are composed of two membranes, the inner and outer mitochondrial membranes. It is here that pyruvate is oxidized to carbon dioxide and the energy released from these reactions is utilized for ATP synthesis. As enzymes are reduced during the OXIDATION processes, reoxidation must occur through the transfer of electrons to the final electron acceptor, oxygen. The terminal enzyme in the electron transport chain is cytochrome C oxidase, and it is this particular MOLECULE that is thought to be the main component in photoactivated biostimulation. Isolated mitochondria display increased ATP synthesis, membrane potential changes, and increased phosphate exchange rates between ADP and ATP when exposed to red and near infrared light. There is theoretical evidence that it is cytochrome C oxidase that is the primary photoacceptor. The main theory of how cytochrome C oxidase may be involved in the absorption of light and stimulation of ATP synthesis goes as follows. The electron transfer in ATP is accelerated as a result of the redox properties of the enzyme changing. There is also the influence of a very small but significant rise in temperature upon absorption of light that indicates a structural changes to the enzyme. During the 4-electron reduction of oxygen to water, free radicals (hydroxyl and superoxide) are produced and the mitochondria may be able to reabsorb these radicals and use them for the oxidative phosphorylation of ADP. Additionally, singlet oxygen plays a minor role in the process. The fact that ATP synthesis is increased during light irradiation of cell cultures led to further research in the area of photo mediated fibroblast proliferation. Studies also suggest that low energy visible light can stimulate the production of reactive Oxygen species. It is thought that the production of H_2O_2 may mediate, directly or indirectly, the phosphorylation of calcium transporters. These results can be directly applied to the field of cardiology. For example, light activation improved preservation of transplant hearts by means of biostimulation, while concurrently reducing infarct size and speeding recovery after HEART damage shows great promise. Other applications of biostimulation are, for instance, the specific illumination of biological photoreceptors identified at various anatomical locations to provide psychological benefits. This effect is shown when fibroblasts are irradiated with a visible light source. The fibroblasts

showed evidence of production of reactive oxygen species after 10 min of irradiation. The reactive oxygen has been documented in psychology journals as an antidepressant, especially when inducing the production of reactive oxygen species in skin. Such oxygen species have been shown in nuclear magnetic imaging (MRI) to participate in SIGNAL transduction pathways in the brain leading to mood changes. A chain of molecular events starts with the initial absorption of light by a photoreceptor, which leads to signal transduction and amplification, and finally results in a photoresponse. The absorbed light activates the respiratory chain and subsequently the oxidation of the NAD pool. This oxidation changes the oxygen status of both the mitochondria and the cytoplasm. As a result the MEMBRANE permeability changes, which in turn has an effect of the Ca^{+} flux. The Ca^{+} ions in turn influence the levels of cyclic nucleotides. The cyclic nucleotides modulate the synthesis of both DNA and RNA. This process is the basis of cell proliferation and as such evidence of photo biostimulation. This process has an upper limit, which is the natural HOMEOSTASIS of the cell, which means that only poorly performing cells can be stimulated. The stimulation effect of light in biological tissues depends on four parameters: the wavelength of the light to target specific receptors, the light fluence rate I , the total irradiation time $\Psi_{\text{source}}(z)$, and the energy density required for activation Δt_{irr} , where $(E/A)_{\text{act}}$ represents the cross-sectional area of the LIGHT SOURCE, or the targeted area itself. Illumination will generally take place under a broad uniform beam, allowing this type of simplification. The stimulation conditions can thus be expressed as A , where the fluence rates for stimulation minimally needs to exceed the threshold fluence rate, $(E/A)_{\text{act}} = \Psi_{\text{source}}(z) * \Delta t_{\text{irr}}$ keeping in mind that the source fluence rate is the light distribution inside the tissue, and decreases with DISTANCE to the light source itself. On the other hand, too high fluence rate will negatively affect the biostimulation process, as described by the ARNDT–SCHULTZ LAW. The conditions for biostimulation will still need to obey the DIFFUSION EQUATION in addition to the Arndt–Schultz law. Additionally specific wavelengths have been identified for biosensors such as HeLa cells, which is activated over a range of wavelengths from 330 to 860 nm, while ATP can be stimulated under irradiation at 632.8 nm (the helium–neon laser wavelength) (also see LASER BIOSTIMULATION and PHOTODYNAMIC THERAPY [PDT]) (see Figure L.130).

Figure L.130 Illustration of the use of low-level light therapy in a health-spa. Potential uses are wrinkle removal/reduction or wound healing stimulation, additional applications are in muscle “rejuvenation” (encouraging the production of ATP and the removal of lactic acid) and “mood-enhancement.”

Low-temperature physics

[general, thermodynamics] Field of science that investigates phenomena at temperatures below normal room temperature, generally even approaching ABSOLUTE ZERO. This field also concerns itself with developing methods to physically establish ultra-low temperatures. Also found under CRYOGENICS.

Low-temperature superconductivity

[general] Several materials reach a condition where electrical RESISTANCE is virtually or totally nonexistent. This condition is reached below a critical temperature ($\psi_{\text{source}}(\infty) \geq \psi_{\text{th}}$). A total of 27 ELEMENTS become superconductive at normal pressure, whereas many composite materials are continuously being developed that can reach SUPERCONDUCTIVITY at relatively high temperatures. The material with the highest temperature for superconductivity currently is a ceramic: T_c , which transitions over to zero resistance at approximately 125 K.

L–S Coupling

[atomic] In certain multielectron ATOM the ORBITAL ANGULAR MOMENTUM ($\text{Tl}_2\text{Ca}_2\text{Ba}_2\text{Cu}_3\text{O}_x$) and the SPIN ANGULAR MOMENTUM (L) combine to produce the TOTAL ANGULAR MOMENTUM: S . More specifically the atomic configuration where this applies generally has weak spin–orbit coupling and the individual electrons join together to form a resultant orbital momentum. The angular momenta of the individual spins also form a resultant spin angular momentum. This applies primarily to open-shell electrons and the following conditions apply: $J = L + S$. The total angular momentum: spin–spin coupling > orbit–orbit coupling > spin–orbit coupling will be able to assume values ranging from J to $|L - S|$. The L–S coupling can be visualized in a vector model of angular momentum. Also referred to as RUSSELL–SAUNDERS COUPLING, published in 1925 (see [Figure L.131](#)).

Figure L.131 (a,b) Illustration of L–S Coupling.

Lubrication

[fluid dynamics] Consider two surfaces, one surface can slide over a second surface with close to negligible resistance (FRICTION) when a LAMINA of viscous FLUID is maintained between them (see [Figure L.132](#)).

Figure L.132 Example of the process of lubrication.

Luciferin

[biomedical, chemical] Material that fluoresces under the influence of OXIDATION, in a CHEMILUMINESCENCE process. A well-known example is produced by the firefly, using a chemical in the Luciferin group. Other examples are found in bacteria, producing yellow light with high quantum yield.

Lucretius (ca. 94–55 BC)

[general] Greek philosopher from the first century BC that described the influence of magnesians on METAL filings, illustrating the effects of MAGNETISM, resulting from a natural MAGNET. Lucretius also postulated that all object (in VACUUM, although vacuum was not reached or defined, but was described as a “void”) would fall at the same rate of velocity change (i.e., constant universal GRAVITATIONAL ACCELERATION).

Luminescence

[biomedical, optics] Spontaneous light emission from decaying electrons as a result of prior excitation. The excitation process may depend on various origins, examples are listed next. Photoluminescence relies on excitation by photons, whereas BIOLUMINESCENCE has its origin in a chemical process mediated by a biological process in a biological entity (e.g., squid, firefly, and algae) and is considered for the visible spectrum only. Every object with a temperature above zero Kelvin will emit ELECTROMAGNETIC RADIATION resulting from thermal VIBRATION of ELECTRIC CHARGES, primarily in the INFRARED, however when the temperature reaches a high enough level the emissions are more energetic and come into the visible range; this process is called incandescence (i.e., BLACK BODY radiation) or thermoluminescence. CHEMILUMINESCENCE involves a oxidation–REDOX REACTION, in which an electric charge is transferred from one chemical species to another; one example magnesium ($L + S$) in contact with water (Mg). ELECTROLUMINESCENCE results from charge acceleration mediated by collision with

electron. One specific example of electroluminescence is in CATHODE RAYS and another is in LED. Another class of luminescence is by means of FRICTION and can be observed when stripping certain PLASTICS from a roll at high velocity; this process is called triboluminescence. Radioluminescence is light emission resulting from excitation by ionizing radiation (e.g., COSMIC RAYS, gamma rays or X-rays). Radioluminescence (scintillation) takes place in polymers containing organic molecules, with the organic molecules being the emitter. Crystalloluminescence is the luminescence resulting from crystallization, the forming of a regular structure due to a gradient in solubility of a SOLUTE in the SOLVENT. Piezoluminescence is the light emission resulting from a sudden change in pressure. Sono-luminescence is generated under BUBBLE CAVITATION, converting the ENERGY released during the collapse of a bubble in excited electrons, sometimes even free electrons (i.e., PLASMA formation) depending on the rate of pressure change and the size of the bubble. Fractoluminescence is the process of light emission due to bond-breaking events in crystalline structures. The latter stand in contrast with the forceful bond-breaking mechanism by means of external energy sources, making this STIMULATED EMISSION (see [Figure L.133](#)).

Figure L.133 Example of bioluminescence of a moon jellyfish.

Luminescent minituft method

[fluid dynamics] Method to investigate surface GAS flow conditions. Single filaments of NYLON that have been impregnated with luminescent dye are attached to a surface and irradiated with ULTRAVIOLET light to visualize the FLOW pattern since single strands are not significantly influencing the flow pattern itself (see [Figure L.134](#)).

Figure L.134 Luminescent micro tuft method used for fluid dynamic analysis. (Courtesy of Central Aerohydrodynamic Institute, TSAGI; Zhukovsky, Moscow, Russia.)

Luminiferous ether

[astronomy, general, optics] The outdated concept regarding the assumed medium that fills the galactic space, allowing for the transportation of ELECTROMAGNETIC RADIATION, in analogue to the medium required for the propagation of SOUND. This concept has been advocated for millennia until the MICHELSON–MORLEY EXPERIMENT in 1881, repeated and published in 1887, dismissed the existence of a medium (ETHER) requirement for light ENERGY transfer and hence for the remaining spectrum as well. The determination of a PHASE shift between two orthogonal paths of light revealed no shifts in fringes of the recombined beam INTERFERENCE pattern, hence discarding the concept of the requirement of and ether medium in the propagation of electromagnetic radiation (*also see* ETHER [AETHER]).

Luminosity function

[astrophysics, general] Two distinctly different definitions are related to “luminosity”: (1) empirical mathematical definition of the galactic luminosity with respect to mass, and hence determine the brightness and potential size of the GALAXY in question. Expressed in apparent luminous MAGNITUDE (H_2O) with respect to a standard RADIANT FLUX magnitude (m_{lum}) of a STAR at a reference DISTANCE of M_{lum} (unit parsec: 10 pc^2) this yields: $1\text{ pc} = 3.26\text{ light-years} = 30.910^{12}\text{ km}$, where $m_{lum} - M_{lum} = -2.5\log((L/4\pi R^2)/[L/4\pi(10\text{ pc}^2)])$ defines the distance to the galaxy, and R is the intrinsic brightness, or radiance (“luminosity”). (2) the average sensitivity of human visual relative discernment of brightness as a function of the EMISSION SPECTRUM. This measures subjectively which of a pair of different-colors is brighter. The parameters was introduced by the Commission Internationale de l’Éclairage (CIE) (see Figure L.135).

Figure L.135 Diagram of luminosity function for galactic phenomena and luminous objects. The abscissa outlines the logarithm of the mass of the galactic object with respect to the mass of the Sun as a standard and the ordinate represents the logarithm of the luminosity ($\log_{10} L/L_{\odot} = xy - b_{\log}$) relative to the luminosity of the Sun; the least bright (“light weight”) stars are on the bottom right.

Luminous efficiency

[biomedical, electronics, solid-state] Conversion efficiency from one form of ENERGY to PHOTON emission. Phosphors on average have a luminous efficiency of the relative amount of 0.6 with respect to photon excitation (1 being the highest, 100%), X-RAY scintillators (e.g., cesium iodide, gadolinium oxysulfide, or cadmium tungstate) used for visualization have a physical MAGNITUDE in the order of L .

Luminous flux

[biomedical, electronics, solid-state] Photometric quantity used to describe the light emission or radiance, with units lumen or candela. The luminous flux is a quantity that relates to PERCEPTION and is linked to the spectral emission profile with respect to the detection by the EYE, whereas radiance is a physical quantity of ENERGY density. One lumen is defined as the luminous flux emitted by a LIGHT SOURCE that emits one candela within one steradian of SOLID ANGLE.

Lumped parameter model

[computational, mechanics] Simplified physical description of a system by gathering similar units or units that construct an ELEMENT into groups, thus reducing the mathematical range into a discrete set of parameters within a finite dimensional confinement. In electrical ENGINEERING modeling of the electrical impulse transmission through human tissues as related to the measurement of an electrocardiogram by symbolizing the tissue as an LRC circuit (parallel and series structure of inductors, resistors, and capacitors, respectively) that can be approached mathematically with the TELEGRAPH EQUATION. Also described as lumped element model.

Lunar tide

[astrophysics, general, geophysics] Fluctuations in the water level as a result of the gravitational attraction from the MOON. The Lunar tide variations are at least two times greater than those resulting from the Sun, keeping in mind that both the Moon is on an elliptic orbit around the EARTH and Earth is on an elliptic orbit around the Sun, providing a range of DISTANCE. The mass (> 15000 photons/MeV) of the Sun is much greater than the Moon but the Moon is much closer and the gravitational pull is proportional to m , where $\sim m/r^3$ is the distance from the galactic object to the point of interaction (see Figure L.136).

Figure L.136 Representation of the lunar tide concept, also with respect to the influence of the proximity and location of the Sun with respect to Earth on the attraction to the fluid mass of surface water.

Lundquist number (r)

[geophysics, fluid dynamics] Dimensionless number used in flowing molten substances, where $Lu = v_a L / \mu$ is the ALFVÉN VELOCITY, with $v_a = B_0 / \sqrt{\mu_{\text{mag}} \rho}$ the MAGNETIC FIELD strength, B_0 the magnetic permeability, μ_{mag} the density, ρ the characteristic length, and L the VISCOSITY.

Lutetium oxy-orthosilicate

[biomedical] Positron emission TOMOGRAPHY scintillation crystal for ENERGY conversion to generate an IMAGE from the pair of dispersive gamma rays.

Lyapunov, Aleksandr Mikhailovich [Алекса́ндр Миха́йлович Ляпуно́в]

[computational, thermodynamics] Russian mathematician and physicist. Lyapunov contributed to the probability theory as proposed by PIERRE DE FERMAT (1601–1665), BLAISE PASCAL (1623–1662), and PIERRE SIMON DE LAPLACE, MARQUIS DE LAPLACE (1749–1827) (see [Figure L.137](#)).

Figure L.137 Aleksandr Mikhailovich Lyapunov (1857–1918).

Lyapunov exponent (η)

[computational] Expression of thermodynamic stability of a introduced by ALEKSANDR MIKHAILOVICH LYAPUNOV (1857–1918), based on the work of JOSEPH LAGRANGE (1736–1813). The Lyapunov exponent describes, based on perturbation of the initial conditions, what the rate of exponential DIVERGENCE is for a dynamic system, expressed as λ_L , where $\lambda_L = \lim_{t \rightarrow \infty} \frac{1}{t} \ln \left(\frac{|\Delta x(X_0, t)|}{|\Delta x_0|} \right)$ is a position in space, with perturbation in position for a second location X_0 all as a function of time ($X_0 + \Delta x_0$). In this, each point creates an orbit or path in dimensional space based on a set of equations of motions particular to the event in question. The Lyapunov exponent determines the “difference” between the two orbits/paths. For t the “orbit” is a fixed point or fixed orbit (e.g., circular) with neutral ACTIVITY, $\lambda_L = 0$ defines as system that is in stable MOTION (e.g., converging), where $\lambda_L < 0$ defines an unstable trajectory that is chaotic as well.

Lyddane–Sachs–Teller relation

[solid-state, thermodynamics] Below the CURIE TEMPERATURE crystals become FERROELECTRIC and the transverse VIBRATION modes (ω_{TO} , with ω the ANGULAR VELOCITY; particularly with respect to far-infrared transmission) approach a frequency of zero while the longitudinal VIBRATION modes (ω) are bound by the Lyddane–Sachs–Teller relation as ω_{LO} . In this case the crystal will become unstable and may disintegrate, more likely it will change its structure, for instance from cubic to tetragonal.

Lyman, Theodore (1874–1954)

[atomic, general, nuclear] Physicist from the United States. Lyman's focus was on SPECTROSCOPY and as such his work provided elemental insight in the excitation emission lines of Hydrogen, referring to the emission wavelength pattern as the LYMAN SERIES (see [Figure L.138](#)).

Figure L.138 Theodore Lyman (1874–1954).

Lyman series

[atomic, general, nuclear] The Hydrogen atomic excitation transition lines described by Lyman, ranging into the deep ULTRAVIOLET. Lyman described his findings in 1906. The emission lines follow the BOHR ATOMIC MODEL, allowing for electron transitions from outer orbits to the innermost ELECTRON SHELLS. Lyman was building on the descriptions of Johann Balmer for his BALMER SERIES. Mathematically, the transition lines with emission wavelength $\omega_{LO}^2/\omega_{TO}^2 = \text{Contant}$ are defined as λ , with $(1/\lambda) = R[(1/1^2) - (1/n^2)] = (2\pi^2 k_0^2 e^4 m_e Z^2 / h^3 c)[(1/1^2) - (1/n^2)]$ the RYDBERG CONSTANT and $R = 1096737.315 \text{ cm}^{-1}$ the indicator for the Bohr electron shell number; n , additionally: $n = 2, 3, 4, \dots$ is the electrostatic constant (also known as Coulomb constant), $k_0 = 8.98755 \times 10^9 \text{ Nm}^2/\text{C}^2$ PLANCK'S CONSTANT, $h = 6.6260755 \times 10^{-34} \text{ Js}$ the charge of a single electron, $e = 1.6021773349 \times 10^{-19} \text{ C}$ the electron mass, and $m_e = (9.1093897 \pm 0.0000054) \times 10^{-31} \text{ kg}$ the speed of light (see [Figure L.139](#)).

Figure L.139 Lyman series in optical decay of excited hydrogen states.

Lyophilization

[biomedical, energy] Mechanism of extraction of water (dehydration) relying on a rapid FREEZING process allowing for SUBLIMATION to remove the water without allowing for biological degradation. Primarily used to preserve biological media that are subject to loss of cellular integrity as well as chemical break down. The cold temperatures slow down the chemical processes (*also see* CRYODESICCATION).

Lysosome

[biomedical, chemical] Organelle in biological CELL that has a digestive function. These cellular pockets contain ACID hydrolase enzyme that is used to assimilate cellular waste material as well as foreign materials and debris produced in the regenerative cellular process (see [Figure L.140](#)).

Figure L.140 Lysosome as essential constituent of cellular organism.

Taylor & Francis

Taylor & Francis Group

<http://taylorandfrancis.com>

MacCormack method

[computational, fluid dynamics, thermodynamics] A NUMERICAL method used in solving fluid-dynamic problems. The method resembles the finite ELEMENT method used in solving the EQUATION OF RADIATIVE TRANSFER in electromagnetic transport. The discretization process will allow solving complex integro-differential equation of orders equal or higher than 3. One specific example is in the calculations with respect to shock waves associated with a SUPERSONIC FLOW. The approach applies, for instance, to the KORTEWEG-DE VRIES EQUATION, which is to the third order in spatial coordinates and first order in the temporal dimension.

Mach, Ernst (1838–1916)

[acoustics, fluid dynamics, general] Austrian physicist whose work in shock waves (in 1877) led to name the supersonic phenomena to be classified under the MACH NUMBER. The “Mach waves” are produced by object traveling faster than the speed of SOUND. The general concepts of Ernst Mach’s philosophy involved specific concepts of INERTIA that freed ALBERT EINSTEIN (1879–1955) from the Newtonian physics ideologies and helped him design his Theory of Relativity principles. The work of Ernest Mach resulted in the development of the Mach number (Ma) (see [Figure M.1](#)).

Figure M.1 Ernst Mach (1838–1916).

Mach angle

[acoustics, fluid dynamics] Half angle of the cone describing the envelope of the pressure WAVE created under the Mach PROPULSION of an object or phenomenon traveling with a velocity v_{object} greater than the speed of SOUND (v_{sonic}): $\mu_{\text{Mach}} = \sin^{-1}(v_{\text{sonic}}/v_{\text{object}})$, the radius (r) of the cone expands with TIME (t) as

$r = v_{\text{sonic}} \times t$, whereas the cone is elongating with length $l = v_{\text{object}} \times t$. The angle outlining the MACH CONE itself is described by $\sin \theta = v_{\text{sonic}} / v_{\text{object}} = 1/Ma$ where v_{sonic} is the speed of sound, which has a sinus of the angle equivalent to the reciprocal Mach number (Ma). The concept was described by ERNST MACH (1838–1916) (see [Figure M.2](#)).

Figure M.2 (a) Mach wave and Mach-lines and (b) Mach angle for different condition.

Mach cone

[acoustics, fluid dynamics] Inside the Mach cone the SONIC BOOM is audible, whereas outside the Mach cone there is silence and no influence from the supersonic phenomenon such as temperature or pressure and FLOW can be observed (see [Figure M.3](#)).

Figure M.3 Mach cone.

Mach number

[fluid dynamics] ($Ma = v/v_{\text{sonic}} = \sqrt{Re \times Wi} = v\sqrt{\rho/E}$) Dimensionless number, developed by ERNEST MACH (1838–1916), indicating the ratio of the velocity (v) of a phenomenon, specifically fluid FLOW, to the speed of sound (v_{sonic}). The SONIC BOOM is an example of the velocity of an object crossing the speed of SOUND, releasing the compression of acoustic ENERGY (i.e., mechanical distortion, an object in MOTION will compress the FLUID directly in-front, superimposed is the propagation of the mechanical vibrations of the object itself) in a different form of acoustic energy. The Mach number defined by the material properties uses the DENSITY (ρ) and the Young's modulus (E), also called elastic modulus. In the definition the following are also used: the REYNOLDS NUMBER and the Weisenberg number. The seed of sound will be a function of the density of the fluid, and is hence slower at higher altitudes. A phenomenon at a velocity less than the speed of sound ($Ma < 1$) is considered subsonic, whereas a phenomenon at a velocity greater than the speed of sound ($Ma > 1$) is considered supersonic. The Mach number of the fluid flow over an AIRFOIL will initially increase and subsequently decrease before detaching at the end of the airfoil. Phenomena under Mach FLUID DYNAMICS have a temperature profile that follows a pattern dictated by the Mach flow conditions and are confined within the MACH CONE. While operating under compression above the Mach velocity, the phenomena are no longer ISENTROPIC. When a SUPERSONIC FLOW is suddenly interrupted, the temperature and pressure will change nonlinearly as described by $T_0 = T \left(1 + [(\gamma - 1)/2] M_\infty^2 \right)$, where T_0 is the stagnation temperature, T the static temperature (ambient), γ the compressibility, and $M_\infty < M_{\text{crit}}$ is lower than the critical Mach number M_{crit} , which indicates the initiation of supersonic flow at a velocity less than the Mach speed. Under the same conditions, the pressure correlates the stagnation pressure P_0 to the static pressure P (ambient) as $P_0 = P \left(1 + [(\gamma - 1)/2] M_\infty^2 \right)^{\gamma/(\gamma-1)}$, where for AIR the exponent is $\gamma/(\gamma - 1) = 3.5$. The Mach number is associated with various context applications of laws of similarity, defining the ratio of forces or parameters in dynamic phenomena by means of a dimensionless number. The laws of similarity correlate the boundary conditions and conditions such as length, time, and mass;

specifically expressed by INERTIA, transform to another similar case, ensuring that the equations remain invariant; acting as “scaling laws” (see Figure M.4).

Figure M.4 Illustration of various objects traveling within certain Mach-number ranges.

Mach number, magnetic

[fluid dynamics] See MAGNETIC MACH NUMBER.

Mach number, sonic flow

[fluid dynamics] See SONIC FLOW.

Mach number, subsonic flow

[fluid dynamics] See SUBSONIC FLOW.

Mach number, supersonic flow

[fluid dynamics] See SUPERSONIC FLOW.

Mach wave

[fluid dynamics] Pressure WAVE generated by an object exceeding the speed of SOUND (Mach one; “sound BARRIER”), reaching supersonic velocity. The pressure wave results from the fact that the compression density EXPANSION or compression (i.e., FLOW) perturbation initiated by the moving object (sound wave) is overcome by the MOTION of the object, changing the direction of flow by an infinitesimally small ANGLE. The motion in the direction of the emitted sound wave is resulting in a compacting fluid due to VISCOSITY effects. Also referred to as “SONIC BOOM.” The Mach wave outlines the pressure OSCILLATION emitted by the moving object (e.g., fighter jet; expanding CAVITATION BUBBLE such as the one that is generated under ultrafast laser irradiation) connecting all crests that are in PHASE, forming a cone with the angle $\mu_{\text{Mach}} = \arcsin(1/Ma) = \arctan(v_n/v_{\text{sonic}})$, the MACH ANGLE, with Ma the MACH NUMBER. The Mach-wave flow direction in the angular expression (θ_{Mach}) is the differential of the Mach angle, and yields the PRESSURE (P) pattern $dP/d\theta_{\text{Mach}} = -(\gamma Ma^2/\sqrt{(Ma^2-1)})P$, with γ the compressibility of the FLUID in which the motion takes

place. The flow angle is derived from the Euler equation as $d\theta_{\text{Mach}} = (v_{\text{sonic}}/v^2)dv_n$, with $v_{\text{sonic}} = \text{constant}$ (the speed of sound), v the propagation velocity of the object introducing the perturbation, and v_n the velocity normal to the WAVEFRONT with respect to the WAVE propagation; assuming ISENTROPIC turbulent flow (see Figure M.5).

Figure M.5 Mach wave concept: side-view of the calculated flow distribution with respect to “characteristic” Mach waves in the supersonic velocity regime around an aerofoil with lenticular profile. The accumulation of lines representing equal flow-velocity provide an indication of location that will generate shockwaves.

Mach’s principle

[fluid dynamics, general] Hypothesis pertaining to the fact that all INERTIA in the UNIVERSE is the result of the interaction between all MATTER in the universe, proposed in 1872. This “invisible web” of interaction is also referred to as the “graviton particle,” the PARTICLE that ORBITS all mass to provide the gravitational COHESION between objects, stretching out to the interaction between galaxies. Named after ERNST MACH (1838–1916).

Mach–Zehnder interferometer method

[fluid dynamics, optics] Optical investigational mechanism devised by ERNST MACH (1838–1916) and LUDWIG ZEHNDER (1854–1949) based on INTERFERENCE, using a particular “by-pass” loop INTERFEROMETER design that is different from the established MICHELSON INTERFEROMETER of the time. Any interferometer uses a mechanism to split the path of a coherent source, such as a laser, to probe the material properties of a medium in one of the two paths. The difference in PHASE of the electromagnetic WAVE is a direct indication of the RELATIVE index of REFRACTION of the medium under investigation. The Mach–Zehnder interferometer uses transmission for the determination of the DIELECTRIC properties of the medium. In comparison, other interferometers such as the Fabry–Perot and Michelson interferometers use the backscattered or reflected light from a specimen (see Figure M.6).

Figure M.6 Mach-Zehnder optical interferometer.

Machine, perpetual-motion

[general, mechanics, thermodynamics] See PERPETUAL MOTION.

Machines

[general, mechanics] Mechanical device designed to perform work. Machines are used to make repetitive and heavy activities less strenuous due to the introduction of an external ENERGY source that can perform a set number of ACTIVITY either under electronic or computer control or by means of mechanical gears or hydraulic FLOW. Geared machines use a toothed connection between axles to reduce the applied force to achieve the required force at the location of the desired action by means of torque, the force multiplied by arm length. The torque transfer between gears is directly proportional to the ratio of the teeth on the sprockets applied in the gear. In hydraulic and pneumatic machines, the force is reduced based on PRESSURE (P) applied to an area (A), where the final force ($F = PA$) is inflicted by an area that is larger than the area of fluid on the side where pressure build-up is introduced: $F_1/F_2 = A_1/A_2$, whereas the pressure is equal on both sides based on the COMMUNICATING VESSELS law (see Figure M.7).

Figure M.7 Rapid prototyping machine constructed from bars and joints and fully functional, once attached to a microprocessor/computer system.

Maclaurin, Colin (1698–1746)

[astrophysics/astronomy, computational, fluid dynamics, mechanics] Mathematician from Scotland. In ALGEBRA, his contribution was a specific series derived from the Taylor series named the Maclaurin series. Additional geometric and calculus-based phenomenological work by Colin Maclaurin was with respect to the shape of rotating bodies presented in 1742 *A Treatise on Fluxions*. In this work, he described the ellipsoidal shape of the EARTH and how this would become more flattened in case the angular momentum increased. The contradictory realization in Maclaurin's work was the description that there will be an optimal configuration. Increasing radius as a result of increasing ANGULAR VELOCITY (ω) will in fact result in bringing the rotation to a halt based on the fact that the ANGULAR MOMENTUM (L) cannot strive for infinity; $L = \omega I$ when the MOMENT OF INERTIA I increases with increasing radius (r), where an infinite radius will define a flat Earth. The optimum will be attained when the earth's radius is approximately 20% greater than its current equatorial radius, with a matching angular velocity of $2.604 \times 10^{-4} \pi$ rad/s, 11 times our current rotation, decreasing the day to 2 h and 8 min (see [Figure M.8](#)).

Figure M.8 Colin Maclaurin (1698–1746).

Maclaurin ellipsoid

[astrophysics/astronomy, fluid dynamics, mechanics] Based on the *Treatise on Fluxions* published in 1742 by COLIN MACLAURIN (1698–1746), a deformation of a round object will run into an energetic dilemma with an increasing angular velocity. The deformation in a round object while spinning around its axis, where the ellipsoidal shape is assumed to increase its primary radius under a continuously advancing angular velocity, with an inherent increasing angular momentum. There is however an energetic constraint that will limit the increase in angular velocity once the optimal angular momentum has been exceeded, from where the ellipsoid

will decrease in angular velocity, while the radius would continue to increase. The expression for the shape of the ellipsoid is defined as $b = (\cos \theta / \sin^3 \theta) [\theta (1 + 2 \cos^2 \theta) - 3 \sin \theta \cos \theta]$, $b = \omega^2 / 2\pi G \rho$ (ρ density; G the gravitational constant; ω the ANGULAR VELOCITY for the rotating PLANET), $\cos \theta = c/a$, $0 < \theta < (\pi/2)$ (see Figure M.9).

Figure M.9 Maclaurin ellipsoid.

Macromolecules

[biomedical, chemical] Molecules with a high molecular mass. Several POLYMER molecules will qualify as macromolecules, as many biological molecules, including the MOLECULE responsible for radiance VISION (gray scale, in RODS) Rhodopsin: molecular weight $35,200 \pm 1200$. Other examples are PLASTICS, graphene, carbohydrates, and DNA. The term macromolecule was introduced in the early 1920s by the German chemist Herman Staudinger (1881–1965) for molecules with in excess of 1000 atoms (see Figure M.10).

Figure M.10 Graphical representation of the biological DNA macro molecule (Deoxyribonucleic acid), encoding the genetic make-up of biological entities.

Macrophage

[biomedical] Cells that form the first line of attack in infections with the name derived from Greek meaning “large eater.” The macrophage performs an active mechanism of encapsulating bacteria or viruses and rendering each individually inactive. The macrophage is approximately three-times the size of a red BLOOD CELL (see [Figure M.11](#)). The macrophage is a biological single cell organism that performs active invagination (“consumption” through the CELL MEMBRANE). During this process the SURFACE TENSION is locally modified.

Figure M.11 Macrophage mechanism, in this case as it applies to an immune response.

Macroscopic

[biomedical, chemical, general, solid-state] Either directly visible by the naked EYE, requiring no additional visual aids to identify the characteristics; or larger in scale than atomic or molecular level, identifying the mechanical and/or fluid-dynamic features of a constituent.

Magic nucleus

[nuclear, solid-state] The NUCLEAR FORCE holding the NEUTRON and protons together appears to be saturable, leaving distinct numbers of nuclides to have a stable configuration due to the fact that each bond NUCLEON interacts only with a few of its nearest neighbors. Magic nuclei have a certain (magic) number of neutron (N) or protons (Z): 2, 8, 20, 28, 50, 82, and 126, which are more tightly bound than nuclei that do not possess nuclides in magic number format. The nuclear magic number performs a similar function as the atomic number for noble gases; pertaining to atomic PHYSICS. The magic number represents a closed (full) PROTON of the neutron shell (*also see* BINDING ENERGY *and* SHELL MODEL).

Magnet

[astrophysics/astronomy, biomedical, energy, quantum, solid-state] Device or object with two POLES that form MAGNETIC FIELD lines connecting from one “positive” pole to a “negative” pole. The magnetic mechanism of action is the result of molecular-sized eddy currents that generate a magnetic field as described by AMPÈRE’S LAW, either molecular-sized eddy currents or larger MACROSCOPIC currents in well-defined conductors. A magnet by definition can only have two balanced poles (i.e., both poles are equally strong to ensure that all magnetic field lines are closed), whereas electric field lines can be produced from a single charge concentration. There are three classes of magnets: (1) permanent magnets, (2) electromagnets (e.g., solenoids), and (3) temporary magnets. A special class of magnet is the QUANTUM MAGNET. Permanent magnets have a constant magnetic field over a finite life-time, which may be extensive in duration. The

EARTH has a magnetic field and is classified as a PERMANENT MAGNET, other permanent magnets are ferromagnetic metallic structures as well as ores. Permanent magnets can lose the magnetic attribute resulting from exposure to high temperatures (random vibrational MOTION will disrupt the alignment of the individual magnetic fields generated by the localized eddy currents), mechanical shock (mechanical vibrations, will miss-align the eddy currents in the medium) or exposure to another external magnetic field. Electromagnets derive the magnetic field from a current applied to a conductive circuit that forms the magnetic field only when the current is flowing. One powerful example of electromagnets is the SOLENOID. Electromagnets are for instance used in MEDICINE for MAGNETIC RESONANCE IMAGING (MRI) as well as in electron microscopes for beam-steering next to MAGNETIC LEVITATION for transportation purposes. In consumer applications, magnets are used for door-closer (both permanent magnets [passive] and electromagnets [active]) as well as in compass for directional orientation. Temporary magnets are forming magnetic capabilities based on the confluence of several phenomena that all need to be present at the same time, and will disappear voluntarily as well. A relatively new class of permanent magnets is the “rare-earth magnet,” identified by the relatively high magnetic field strength per unit mass. The rare-earth ELEMENTS can be magnetized because their four “f” electron orbitals (as described in the BOHR ATOMIC MODEL) are not filled. The orbitals are the subpart of the shell that in turn is the subpart of the shells. Shells are grouped and named as follows: K, L, M, N, O, P, and Q. The subshells are named as s, p, d, f, and g. In the Bohr atomic model, the f shell may contain a total of 7 pairs of electrons, 14 in total, each with spins pointing in one direction, in accordance with HUNDS’ RULE. Having these electrons aligned gives rise to stronger magnetic fields. Rare-earth magnets are made from rare-earth elements, which entails primarily costly resources, not directly occurring in small quantities, rather only obtainable or produced in small quantities (e.g., Nd-Fe-B and Sm-Co). Typically these are compounds or composites that have IRON (Fe) as part of the matrix.

Magnetic

[astrophysics/astronomy, energy, nuclear, solid-state] The phenomenon and condition of possessing MAGNETIC FIELD lines, more specifically, being a MAGNET. (*see* MAGNETIC FIELD) (*see* [Figure M.12](#)).

Figure M.12 Magnet used in scrap yard (i.e., electromagnet), hauling junk metal.

Magnetic axis

[electromagnetism, geophysics] The axis connecting the earth’s MAGNETIC NORTH POLE to the MAGNETIC SOUTH POLE. This is not the same axis that connects the GEOGRAPHIC NORTH pole to the GEOGRAPHIC SOUTH pole. The magnetic axis is not fixed, and has switched 180° several times over the past millions of years. Based on geological

findings, there is evidence suggesting that the NORTH and south poles may have totally switched positions more than 65 times over the past 600 million years. See PALEOMAGNETISM and POLES (see [Figure M.13](#)).

Figure M.13 Magnetic axis versus the geographic axis of the Earth.

Magnetic buoyancy

[astrophysics/astronomy, energy, geophysics] Due to a gradient in magnetic flux-tubes in the solar structure, the MAGNETIC FIELD at the solar surface will be smaller than on the interior, as will be the associated magnetic pressure. Based on the application of the GAS LAW, the density will be less inside the FLUX tube than in the main volume of the Sun. The internal magnetic field can make portions of compressible FLUID less dense than its surroundings, resulting in an upward FLOW under the influence of GRAVITY, the denser “heavier” medium surrounding the less dense medium is pushed out by gravitational buoyancy. This mass imbalance

creates a hydrostatic pressure with resulting flux tubes, providing the mechanism of action for eruptions resulting from magnetic buoyancy (e.g., solar flare) (see [Figure M.14](#)).

Figure M.14 (a) Magnetic buoyancy in the plasma layers within the sun's volume and (b) solar flare.

Magnetic cooling

[atomic, nuclear] At extremely low temperatures (especially below $T = 1\text{ K}$), it becomes difficult to decrease the temperature of a medium by ordinary means. The use of adiabatic magnetization has been successful for both paramagnetic salts and nuclear cooling, introduced by the chemist William Francis Giauque (1895–1982) from the United States in 1933 for salts, and by means of NUCLEAR MAGNETIC MOMENT in 1955 for cooling of the atomic core by the physicist Nicholas Kurti (1908–1998) from Hungary and by PETER DEBYE (1884–1966) from the Netherlands. The phenomenon was however observed prior to this in 1917 by the physicist Pierre-Ernest Weiss (1865–1940) from France, and the physicist A. Piccard (1884–1962) from Switzerland in 1917. For salts, the ENTROPY (S) can be controlled by an externally applied magnetic field (B) based on the TOTAL ANGULAR MOMENTUM (with quantum number J) as $S = R \ln(2J + 1)$, with $R = 8.3144621(75)\text{ J/Kmol}$ the universal gas constant. Similarly, for the NUCLEUS, the NUCLEAR ANGULAR MOMENTUM is I , with entropy $S = R \ln(2I + 1) - (1/2)\Lambda(B/T)$, where Λ is the Curie constant. For the nuclear cooling, the temperature reduction, starting at an initial temperature $T_i \propto mK$ (specifically $T_i < 20\text{ mK}$) under ADIABATIC DEMAGNETIZATION by means of ISENTROPIC reduction of the applied MAGNETIC FIELD from B_i to B_f , yields: $T_f = T_i/B_i \sqrt{(B_f^2 + b_m^2)}$, with b_m the internal magnetic field of the nucleus of the ELEMENT or alloy (e.g., for copper nuclei: $b_m = 0.3\text{ mT}$). Another form of magnetic cooling that applies to the

free electrons in a CONDUCTOR (with temperature T_e), with respect to the nuclear SPIN temperature T_n , yields: $T_e/T_n - 1 = \mu_0 \kappa_K [\dot{Q}_e / \Lambda(B^2 + b_m^2)]$, where κ_K is the Korringa constant and $\dot{Q}_e$ is the rate of heat exchange due to the freely moving electrons. Additional mechanisms of nuclear cooling by means of magnetic field involve the use of polarized magnetic field, and the change of direction of POLARIZATION with respect to the nuclear alignment, next to cooling in cascaded stages with different DOPING materials for a specific medium (see [Figure M.15](#)).

Figure M.15 Outline for the concept of magnetic cooling.

Magnetic dipole

[electromagnetism, general] Two POLES of equal and opposite MAGNITUDE at a fixed DISTANCE. A prime example is the BAR MAGNET. An ATOM can also form a magnetic dipole based on the angular momentum of the electrons, and more specifically when the atomic structure has unpaired electrons. The magnetic dipole is characterized by a magnetic dipole moment. The electrons in the atomic structure act as current loops, however without a fixed orientation (not providing a SOLENOID configuration). In electric circuits, a closed current loop, that generates a MAGNETIC FIELD perpendicular to the plane of the loop in a direction based on the right-hand rule. The current loop will generate a torque ($\vec{\tau}$) when exposed to an external magnetic field ($\vec{B}$) expressed as $\vec{\tau} = \vec{M}_{\text{current}} \times \vec{B}$, where $\vec{M}_{\text{current}}$ is the magnetic dipole moment of the current loop (see [Figure M.16](#)).

Figure M.16 Magnetic dipole: Earth with the central magnetic portrayed as a bar magnet; magnetic field lines encapsulating Earth in equimagnetic concentric toroidal shells. Note: the earth's magnetic north pole is on the geographic south side.

Magnetic dipole moment ($\vec{M}_{\text{current}}$)

[general] The potential of a current loop to express itself with a torque, defined as $\vec{M}_{\text{current}} = NIA\vec{n}$ where I is the current in the loop, N is the number of loops in the device carrying the current, A is the area outlined by the loop, and $\vec{n}$ is a unit vector in the direction perpendicular to the plane of the loop; the direction can be found by applying the right-hand rule.

Magnetic field

[biomedical, electromagnetism, geophysics] {use: imaging (MRI), guidance (compass), actuation}—An electric current generates a magnetic field according to AMPERE'S LAW: $\vec{B} = \mu_0(I/2\pi r)$, with μ_0 the magnetic permeability of the medium, and r the DISTANCE to the current. The magnetic field direction can be derived using the "right-hand rule," where the fist of the right hand illustrates the current in the direction of the thumb and the fingers the direction of the produced magnetic field. The direction of the magnetic field lines is by convention from the *north* to the *south* pole, and magnetic field lines are always closed, which means they will in certain cases pass through the device generating the magnetic field. For a coil, the magnetic field strength is generated by a loop current and is $\vec{B} = N\mu_0(I/2r)$, with N the number of coil revolutions. The magnetic field lines for a coil are shown in the figure. Similarly the EARTH has a magnetic field that is generated by the FLUID CORE, which is FERROELECTRIC. The geological North Pole of the Earth is actually the pool indicated by the north pole of a compass MAGNET, and is as such truly a MAGNETIC SOUTH POLE. The earth's magnetic field is influenced by the SOLAR WIND, which deforms the magnetic field lines as shown in the illustration. The magnetic field lines on a global (close to the surface) level are influenced by geological phenomena and follows patterns as shown by the magnetic field line diagram in the following illustration using data from 1922 as published in "Westphal, W.H., Physik, Ein Lehrbuch für Studierende; Julius Springer, Berlin 1928." The earth's magnetic field also attracts charged particles, specifically those released from the Sun during a solar flare. The charged particles attracted by the earth's magnetic field are accelerated as they approach the pools and accelerating charges produce ELECTROMAGNETIC RADIATION, which is visible by the "NORTHERN LIGHTS" or AURORA BOREALIS as well as the AURORA AUSTRALIS ("Southern Lights"). Magnetic field can also be used for magnetic imaging when modulated by a RADIO-FREQUENCY (RF) pattern as in MAGNETIC RESONANCE IMAGING: MRI and fMRI. Another application of magnetic field attraction is in MOTION CONTROL, such as a VOICE COIL in a loud SPEAKER. Animals also use magnetic fields to orient themselves and locate prey as outlined in ELECTRORECEPTION (see Figure M.17).

(a)

Figure M.17 (a) Close-up of ferromagnetic fluid flowing between two adjacent magnets under the influence of the magnetic field-lines, as portrayed by the fluidic spikes. (Continued)

Figure M.17 (Continued) (b) Representation of the force relationship to the magnetic field using the right-hand rule, respectively, the left-hand rule.

Magnetic flowmeter

[biomedical, fluid dynamics] Flow of conductive media or charged particles will induce an electromotive force when exposed to an external MAGNETIC FIELD, hence allowing for noninvasive FLOW rate determination. The voltage generated is proportional to the MAGNITUDE of the magnetic field, the average flow rate, the density of the FLUID flow, as well as the length of the conducting medium flow tube. The measurement of the average flow velocity is based on the FARADAY LAW for electromagnetic induction. Magnetic flowmeters are used in fixed positions on conduits as well as in the format of a clamp-on for temporary flow verification. In medical applications, this type of flowmeter is used to measure the BLOOD flow locally in surgically exposed vessels for diagnostic purposes (see [Figure M.18](#)).

Figure M.18 Magnetic flowmeter principle, using the perceived flow of charges represented as a current.

Magnetic flux (Φ_M)

[general] The magnetic field-line density for a MAGNETIC FIELD ($\vec{B}$) taken perpendicular to an area $\vec{A}$ as $\Phi_M = \vec{B} \cdot \vec{A} = |\vec{B}| |\vec{A}| \cos \theta$. The units for magnetic flux are tesla per square meter, which is weber (in honor of a magnetic pioneer from Germany: WILHELM EDUARD WEBER [1804–1891]) $1 (T/m^2) = 1 Wb$.

Magnetic force (F_M)

[general] The force exerted on charged particles by a MAGNETIC FIELD ($\vec{B}$) treats the moving particles with charge q and velocity $\vec{v}$ as a current under ANGLE θ with the applied field: $F_M = q\vec{v} \times \vec{B}$. The direction of the force follows the “right-hand rule.” For a confined current ($\vec{I}$) in a wire with length ℓ , the force becomes:

$F_M = \ell \vec{I} \times \vec{B}$. This is the force that provides the mechanism-of-action for the formation of the AURORA BOREALIS, the charge stream emitted from the Sun under the earth's magnetic field (*also see* LORENTZ FORCE and AMPÈRE'S LAW).

Magnetic levitation

[electromagnetism, mechanics] Several versions are available, but the main principle remains the induction of a current in coils mounted in a wagon that produces an inherent MAGNETIC FIELD that is opposite to the inducing magnetic field applied from the outside, resulting in repulsion. The induction is based on the FARADAY LAW (described by the English physicist MICHAEL FARADAY [1791–1867] in 1831) and LENZ'S LAW (as introduced by the Russian/Baltic/German physicist HEINRICH FRIEDRICH EMIL LENZ [1804–1865]). The external magnetic field is generated by means of coils mounted in a track that supports the wagon, the LEVITATION coils. The coils in the wagon are ideally superconductors to minimize the resistive loss of current. The PROPULSION of the wagon is achieved by a second set of coils, in a separate location, such as the sides of the track. The propulsion coils are energized in a WAVE pattern along the length of the track, creating a temporal magnetic gradient, providing the magnetic force to move the wagon in the direction of the gradient. The wagon will “float” under the magnetic field repulsion, providing conditions of minimal FRICTION, apart from the AIR resistance during movement. As a fail-safe, there are wheels mounted underneath the wagon in cases when there is no external magnetic field (also found as maglev) (see Figure M.19).

Figure M.19 The concept of magnetic levitation applied to train transport.

Magnetic Mach number

[electromagnetism, fluid dynamics] In magneto-hydrodynamics, the forces are distributed based on origin, when the Lorentz forces are relatively equivalent to the inertial forces, this results in a relative equilibrium between the magnetic ENERGY and the kinetic energy. The LORENTZ FORCE (F_L) resulting from an external MAGNETIC FIELD ($\vec{B}$) $F_L = \vec{j} \times \vec{B}$, where $\vec{j} = \text{curl}(\vec{B}/\mu^*)$ is the associated current density, with μ^* the DIELECTRIC permeability. The inertial force (F_i) density is represented by the fluid DENSITY (ρ) and the velocity ($\vec{u}$) vector distribution described as $F_i = \rho \vec{u} \cdot \nabla \vec{u}$. The equilibrium in forces yields a Magnetic Mach number of approximately 1: $\mathcal{A}_{\text{Mach}}^2 = [((1/2)\rho u^2)/(B^2/2\mu^*)] \sim 1$. This is sometimes also referred to as the ALFVÉN NUMBER.

Magnetic materials, permeability of

[general] Material property that is representative of the MAGNETIC behavior of the medium. The magnetic permeability of VACUUM has been established as $\mu_0 = 4\pi \times 10^{-7} \text{ H/m}$, where the magnetic permeability of a medium can be referenced in relation to the permeability of vacuum by means of the RELATIVE PERMEABILITY ($0 \leq \mu_r \leq 1$) or as its own permeability $\mu_{\text{material}} = \mu_r \mu_0$. Ferromagnetic media generally have a relative permeability greater than 1, AIR and water can be described by $\mu_r \cong 1$ (deviation in the five decimal position or less), while for diamagnetic materials $\mu_r < 1$; $\mu_{\text{material}} < \mu_0$. For ferromagnetic materials, the magnetic permeability may not be constant, rather be a function of the applied MAGNETIC FIELD as well as a function of temperature.

Magnetic moment (μ_{mag})

[general, nuclear] The moment (compare with torque $[\tau]$ from mechanical force $[F]$ applied over an arm attached to a hinge point with length $[\ell]$: $\tau = Fd$) resulting from a magnetization ($\vec{m}_{\text{mag}}$) that is induced by a current loop ($\vec{J}$) in a volume of medium (dV) expressed as $d\mu_{\text{mag}} = \vec{m}_{\text{mag}} dV = (1/c) \vec{J} d\vec{S}$, where c is the speed of light and $d\vec{S}$ is the vector normal to the surface of the volume ELEMENT. The MAGNITUDE of the magnetic moment is $\mu_{\text{mag}} = (-e/c)(v/2\pi r)(\pi r^2)$, where e is the electron charge in Coulomb, $c = 2.99792458 \times 10^8 \text{ m/s}$ (the speed of light), and r is the radius of the orbit of an electron revolving with speed v . Alternatively $\mu_{\text{mag}} = -g_e \beta_m \vec{s}$, where $g_e = 2.0023...$ the Landé factor, the Bohr magneton $\beta_m = \hbar|e|/2m_e$ ($m_e = 9.10939 \times 10^{-31} \text{ kg}$ the electron mass), and the spin $\vec{s} = \hbar s$ (in this case specifically for an electron with the SPIN quantum number s and where $\hbar = h/2\pi$, which is PLANCK'S CONSTANT $h = 6.626 \times 10^{-34} \text{ J/Hz}$ divided by 2π). The electron will also have an orbital angular moment $\gamma_J = \mu_{\text{mag}}/\hbar J$, with J an integer. The current loop can be isolated in a small volume with neighboring volumes having a random orientation of the respective magnetization. While exposed to an external MAGNETIC FIELD or other influence, they may all line up to make the entire object a MAGNET (e.g., IRON). Object and media that are paramagnetic cannot be fully magnetized, only a fraction of the internal magnetic moments will line up under an applied field, increasing the total magnetic field strength, but marginally. Substances that are ferromagnetic can be magnetized (made to act as a magnet), and this is the result of the fact that the substance has a MAGNETIC SUSCEPTIBILITY. Although a diamagnetic medium has no internal MAGNETIC DIPOLE moment, it will have an effective magnetic field of its own in the opposite direction of an applied external magnetic field. Magnetic moments result from various currents such as orbital electrons, spin, and deuterons as well as ions to name a few.

Magnetic monopole

[general] The theoretical hold-out in the Gauss' law for MAGNETISM that relies on the fact that MAGNETIC FIELD lines have a starting point and an end point. In case the magnetic monopole would exist (so far no theoretical or experimental indication to the contrary is provided), the integral in Gauss' law will not render zero, right now it still holds for the integral over a surface (S) with surface area ELEMENTS da and normal vector $\vec{n}$ enclosing a magnetic field (B): $\oint_S \vec{B} \cdot \vec{n} da = 0$.

Magnetic north pole

[astrophysics/astronomy, general, geophysics] The pole on the earth's globe where the MAGNETIC FIELD lines originate, located near the GEOGRAPHIC SOUTH Pole. The magnetic field lines terminate at the magnetic south

pole, from where the magnetic field continues through the EARTH as a magnetic CONDUCTOR to re-emerge on the magnetic north pole, since per definition magnetic field lines form closed loops (see [Figure M.20](#)).

Figure M.20 Ions emitted from solar flares drawn in by the magnetic field pointing into the “North Pole” (Note: the geographic North Pole is the magnetic south pole). The resulting effect is expressed by the magnetic force accelerating the ions, hence generating the emission of electromagnetic radiation (i.e., the critical aspect of accelerated charge).

M

Magnetic poles

[general, geophysics] The locations on a MAGNETIC medium from where the MAGNETIC FIELD lines originate, respectively, are terminated, and continue through the material to form a closed loop. Solid state magnets are available in various shapes and sizes, most familiar shapes are the BAR MAGNET, horse-shoe magnet next to the solenoid ELECTROMAGNET. The EARTH acts as a bar magnet with a NORTH and south pole, providing a three-dimensional magnetic field loop. The magnetic field of the Earth is presumably the result of the rotational MOTION of the IRON inner core, acting as a current loop, as defined by AMPÈRE’S LAW, in close similarity to a SOLENOID. The POLES of the Earth’s magnetic field are not fixed and continue to “wander.” The earth’s magnetic field has changed orientation by 180° many times in the history of the Earth, the last time approximately 780,000 years ago. The magnetic field lines in the Earth’s ATMOSPHERE do not follow perfectly straight lines due to influences from magnetic media, such as granite, large bodies of water, and geographical topography (mountain ridges, valleys). A compass will align with the local magnetic field lines, hence providing a mechanism for identification of the locations of the magnetic poles. A compass indicating the magnetic poles can be used for orientation

purposes and planning a travel route, in comparison to the “global positioning system” that uses a chain of geo-synchronous orbit satellites to provide triangulation (see [Figure M.21](#)).

Figure M.21 Magnetic poles of bar magnets and horse-shoe magnet, “north” attracting “south.”

Magnetic quantum number

[nuclear] See QUANTUM NUMBER.

Magnetic resonance

[atomic, nuclear] Protons have a MAGNETIC moment, similar to a BAR MAGNET, that can be guided by an external MAGNETIC FIELD. A magnetic moment will precess around the externally applied continuous (steady-state) magnetic field with a frequency that is proportional to the magnetic field strength: the Larmor frequency. When applying an additional oscillating magnetic field that has an orientation perpendicular to the steady-state magnetic field, the magnetic moment can be “persuaded” to flip direction between SPIN states (“up” or “down”) when the OSCILLATION of the external field matches the LARMOR PRECESSION frequency. This principle specifically applies to a very simple magnetic moment: the proton. The proton’s magnetic orientation resonance ENERGY is emitted in the form of ELECTROMAGNETIC RADIATION in the RF spectrum. The RF spectrum can be detected externally, by applying a gradient in the magnetic field the Larmor frequency for the protons will be location specific, with associated differences in RESONANCE conditions. In this manner, the location specific magnetic resonance can be used for three-dimensional location specific SIGNAL collection. The use of several detectors will provide the line of intersect for each instantaneous RF signal, hence yielding the origin of the PROTON spin. The process of reconstruction based on the multiple lines of intersect and location specific magnetic field strength allows for three-dimensional imaging.

This magnetic resonance process is used apropos in magnetic resonance imaging (MRI), also referred to as nuclear magnetic resonance imaging (NMR imaging) (see [Figure M.22](#)).

Figure M.22 A charged particle with nonzero spin will act as a magnet that will align with an external applied magnetic field, in particular it will continuously align with a changing external magnetic field and will be in sync with the frequency of the applied changing field, in resonance.

Magnetic resonance imaging (MRI)

[biomedical, electromagnetism, general, nuclear, quantum] Tomographic mechanism of action that generates images of imbedded physical and chemical properties by measuring the NUCLEAR MAGNETIC RESONANCE (NMR) signal emitted by individual and specific atomic and molecular structures with certain ENERGY configurations. The principle of NMR was first described in 1946 by FELIX BLOCH (1905–1983) and EDWARD MILLS PURCELL (1912–1997). It was not until 1973 that MR imaging was made feasible by Paul C. Lauterbur (1929–2007) and Sir Peter Mansfield (1933–), resulting in the implementation of the first clinical scanners by the beginning of the 1980s. The mechanism of action for MRI relies on nuclear excitation and subsequent electromagnetic emission of an inhomogeneous body of material, either biological or solid state by means of irradiation with electromagnetic waves in the range of RF. MRI is most known for its applications in MEDICINE for diagnostic screening. The photonic energy of the ELECTROMAGNETIC RADIATION is much less than what is used in ionizing radiation, such as X-RAY imaging and computed TOMOGRAPHY. The NMR phenomenon is fundamentally quantum PHYSICS. The phenomenon relies on the fact that all atomic nuclei possess an angular momentum with associated respective spins. Nuclei that have an odd number of protons, neutrons, or both have a discrete angular momentum. Hydrogen is one ELEMENT with those properties and is available in abundance in the biological entities such as the HUMAN BODY. The nuclear SPIN can be manipulated as if it were a tiny MAGNET due to the fact that a spinning charged PARTICLE creates an ELECTROMAGNETIC FIELD. When no external MAGNETIC FIELD is applied, the spins are oriented in a random fashion, hence canceling each other, with subsequent zero net magnetization. When an external magnetic field (B_0) is applied, the respective nuclear spins align themselves in the direction of the applied field as a function of time. Slightly more than half the spins align parallel to the direction of B_0 (the z -direction), while the remaining align in the opposite direction (down or antiparallel). The resulting net magnetization (M) points in the B_0 direction (longitudinal direction). The MR imaging concept relies on the fact that the local induced magnetic orientation will recoil to the base state once the external magnetic field is removed, or changes direction. Faraday's law mandates that a changing magnetic field induces an electric current that takes place in the detection mechanism in a receiver coil oriented perpendicular to the MAGNETIC field. The magnetization vector (M) is designed to oscillate and under external coercion will tip within the transverse xy plane. The spin axis will form PRECESSION around the z -axis with the Larmor frequency ω_{Larmor} , which is specific to the medium and the applied field as $\omega_{\text{Larmor}} = \gamma B$, where γ is the GYROMAGNETIC RATIO and B is the magnetic field strength. Thus, the transverse magnetization component M_{xy} induces a SIGNAL in the receiver coil.

RF excitation

The magnetization M is tipped into the transverse plane using an RF excitation pulse, which generates an external weak MAGNETIC FIELD (B_1) perpendicular to M , for example, in the x -direction. It should be noted that the B_1 field is not stationary; it is rotating in the xy plane around the z -axis with a Larmor frequency, ω_0 , in the same direction as SPIN precession, which creates the RESONANCE condition. During the period of time when B_1 is on, M lies under the influence of two magnetic fields: a strong stationary field (B_0) in the z -direction and a weak rotating field (B_1) in the xy plane orthogonal to B_0 . This results in M simultaneously precesses quickly around the z -direction with a Larmor frequency ω_0 , and slowly around the x -direction with a frequency ω_1 , where $\omega_0 = \gamma B_0$, and $\omega_1 = \gamma B_1$. This results in a spiral MOTION of M from the z -direction toward the xy plane. Because $\omega_1 \ll \omega_0$, M ends up tipped toward the xy plane with flip ANGLE depending on the RF pulse strength and duration. Excitation RF pulses are referred to with the angle by which the magnetization vector is tipped: for example a 45° RF pulse tips the magnetization vector half way into the transverse plane, while a 90° RF pulse tips the magnetization vector all the way into the transverse plane.

Bloch Equation

The Bloch equation describes the magnetization vector behavior under the NMR phenomenon: $dM/dt = M \times \gamma B$, where M = magnetization vector, B = magnetic field, t = time, and γ is the GYROMAGNETIC RATIO. The operator $\times$ (i.e., cross-product) in this case represents vector multiplication (see Figure M.23).

Magnetic Reynolds number

[computational, hydrodynamics, magnetism] See REYNOLDS NUMBER, MAGNETIC.

Magnetic South Pole

[general, geophysics] Physical terminal point for MAGNETIC FIELD lines on the EARTH as a MAGNET, located near the GEOGRAPHIC NORTH pole (northern hemisphere).

M

Magnetic spectrometer

[nuclear] Selective isolation of moving charged particles based on their kinetic ENERGY ($KE = (1/2)mv^2$, based on MASS (m) and velocity (v); using single value charges, the ELECTRIC FIELD (E) based acceleration will yield a uniform velocity potential) when exposed to an external magnetic field that causes the trajectory of the PARTICLE to curve due to the Lorentz force. The force on the CHARGE (q) results in an acceleration that provides a final velocity when the charge emerges from the ANODE of the accelerator potential with acceleration in the direction of the applied gradient in ELECTRIC POTENTIAL (V): $\vec{a} = q\vec{E}/m$. The loss in electric potential energy equates to the gain in kinetic energy as $q(V_2 - V_1) = (1/2)mv_2^2 - (1/2)mv_1^2$, providing the final velocity as a function of mass. The radius of curvature for the path of the moving charged particle exposed to a homogeneous, uniform, steady state MAGNETIC FIELD (B) is expressed by $r = mv/qB$. The terminal location of the particle on a linear sensor array is hence an indication of the mass of the particle. Using this principle, the chemical composition of an unknown material (constructed from a multitude of chemicals) can hence be deciphered, as well as the chemical structure and composition of

specific molecules, next to the analysis of SUBATOMIC PARTICLES in a CYCLOTRON. Also known as mass spectrometer (see BUBBLE CHAMBER and CLOUD CHAMBER) (see Figure M.24).

Figure M.24 Magnetic spectrometer, also known as mass spectrometer.

Magnetic susceptibility (χ_{mag})

[atomic, general, nuclear, solid-state] The tendency of individual MAGNETIC DIPOLE moments (μ_{mag}) within a substance to line up with an externally applied MAGNETIC FIELD as thermal agitation (at temperature T) will continue to mis-align the moments, expressed as $\chi_{\text{mag}} = \mu_0 N \mu_{\text{mag}}^2 / 3kT$, where $\mu_0 = 4\pi \times 10^{-7} \text{ Tm/A}$ is the DIELECTRIC permeability of VACUUM, N is the number of magnetic dipoles per unit volume and $k = 1.380658 \times 10^{-23} \text{ J/K}$ is the Boltzmann constant. The principle was described by PAUL LANGEVIN (1872–1946).

Magnetism

[astrophysics/astronomy, energy, general, solid-state] The phenomena created by the MAGNET, more specifically by the MAGNETIC FIELD lines from a magnetic object (see MAGNET). The concept of magnetic field lines was illustrated in 1269 by Pierre de Maricourt (thirteenth century scientist; often quoted by his friend the English philosopher and friar ROGER BACON [1220–1292]), who shaped a LODESTONE into a sphere and placed IRON splinters on its surface and the METAL slivers aligned themselves with the magnetic field lines running from pole to pole, while at the pole they would stand erect, while the meridian circle would converge at the respective opposing POLES.

Magnetoencephalography (MEG)

[biomedical, imaging] Noninvasive imaging mechanism to study the ACTIVITY of the brain as a function of location in three-dimensional format. DEPOLARIZATION of single nerves creates a MAGNETIC FIELD in a similar fashion to an electric current in a wire (AMPERE'S LAW). The application of state-of-the-art magnetic sensors can detect the emerging magnetic field as a function of location in a tomographic imaging setting using the intersect of lines of detection for multiple sensor units. Magnetic sensors can detect a field strength as small as $1.0 \times 10^{-15} T$. Magnetoencephalographic imaging can provide high RESOLUTION details about the stimulated or spontaneous neural activities in the brain. Stimulated activation imaging provides significant details about potential damage to the brain as well as distinguishing from a mismatch in data communications to the brain (e.g., neurological damage to the main neurons leading to the brains such as the optic nerve and the auditory nerve). Generally the MEG imaging technique relies on arrays of SQUIDS (superconducting quantum INTERFERENCE devices) (see Figure M.25).

Figure M.25 (a) Magnetoencephalography machine used to image the brain activity. (b) MEG of a person performing mental tasks (frontal lobe activity).

Magnetohydrodynamics

[electromagnetism, general, mechanics] The FLOW of charged particles in any medium, ranging from PLASMA to ionic solutions. Seawater has a substantial electric conductivity due to its SALT content. The conductivity of seawater is $\sigma \cong 3.2 \text{ S/m}$. As a result of AMPÈRE'S LAW and Maxwell's revisions, the flow of electric particles in the earth's MAGNETIC FIELD generates a magnetic field of its own, expressed as $[\partial \vec{B}(r, t) / \partial t] = \nabla \times (\vec{u}(r, t) \times \vec{B}(r, t)) + \eta \nabla^2 \vec{B}(r, t)$, where $\vec{B}(r, t)$ is the FLUX density of the magnetic field, $\vec{u}(r, t)$ is the FLOW velocity of the FLUID, and $\eta \equiv (\mu_0 \sigma)^{-1}$ is the magnetic DIFFUSIVITY, with μ_0 the magnetic

permeability. One boundary condition follows from the fact that by definition there are no magnetic charges, and $\vec{B}(r, t)$ is solenoidal: $\nabla \cdot \vec{B}(r, t) = 0$. The Swedish electrical engineer and physicist HANNES OLOF GÖSTA ALFVÉN (1908–1995) has been attributed to be the founder of this particular field of PHYSICS (*also see* MAGNETIC MACH NUMBER).

Magneton

[atomic, nuclear] Expression for MAGNETIC DIPOLE moment resulting from a spinning spherical particle. This hypothetical spherical PARTICLE can be represented either by electrons in an orbit around the NUCLEUS next to the NUCLEAR MAGNETIC MOMENT as an independent phenomenon. The electron magnetic dipole moment, the BOHR MAGNETON, is expressed as $\mu_B = e\hbar/2m_e c$ where, $\hbar = h/2\pi$ with $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the Planck's constant, m_e the electron mass, $e = 1.60217657 \times 10^{-19} \text{ C}$ the electron charge, and c the speed of light. The nucleus considered as a “solid” sphere has a nuclear magnetic moment $\mu_N = e\hbar/2m_p c$, where m_p is the proton mass.

Magnetosphere

[energy, geophysics] The earth's MAGNETIC FIELD is inclined with respect to the EARTH'S ROTATIONAL AXIS at an ANGLE of approximately 11° . The magnetosphere interacts with the IONIC and ELECTROMAGNETIC events and in the IONOSPHERE this will create INTERFERENCE with communication in addition to the occurrence of the AURORA events (see [Figure M.26](#)).

Figure M.26 Illustration of the earth's magnetosphere, and the influence of the sun's magnetic field.

Magnetostriktion

[imaging, solid-state] Change in the shape of an oscillating MAGNET under the influence of an external MAGNETIC FIELD. The magnet's shape change can be orchestrated by rearranging the molecular structure. Magnetic devices however appear to be limited to an upper modulation frequency of 500 kHz. This phenomenon can be applied for general SOUND generation as well as ULTRASOUND generation.

Magnetotactic bacterium

[biomedical, general] Bacteria that use **MAGNETISM** as a means to guide their path, the bacterial organism contains a chain of magnetite crystals, which create a functional compass needle. The magnetotactic bacteria were discovered in 1975 by Richard P. Blakemore (1950–) (see [Figure M.27](#)).

Figure M.27 Configuration of the mechanism-of action for Magnetotactic bacteria. Inset: Magnetotactic bacterium specimen.

M

Magnification (M_{mag})

[general, optics] The perceived increase (whole integer magnification) or decrease (fractional magnification) in size or details in an **IMAGE** formed with **ELECTROMAGNETIC RADIATION**, or electron beam. The **EYE** forms a real image on the **RETINA** that is smaller in size than the original object. A magnifying **GLASS**, microscope, or **X-RAY** machine forms an image that has a greater spatial resolution than can be observed with the naked eye. Generally, the **RESOLUTION** or **RESOLVING POWER** of an imaging system is a direct function of the probing **WAVELENGTH** (λ), limiting what can be distinguished is at minimum half the wavelength, or more formally the resolving power is defined by the **APERTURE** (D) of the device as $P = D/1.22\lambda$ (also see **RALEIGH CRITERION** and **ABBE CONSTANT**). The maximum resolution that is useful in a **MICROSCOPE** is on the order of $0.1 \mu\text{m} = 10^{-7} \text{m}$ at a magnification of $M_{\text{mag}} = 600$ times (although with artificial means $M_{\text{mag}} = 2000$ can be made efficient for diagnostic purposes), where the spatial separation of the **RODS** and **CONES** forms the limit factor in what can be discriminated to the lower level, next to the wavelength, usually taken on the average of the visible spectrum at $\lambda = 530 \text{nm}$. An **ELECTRON MICROSCOPE** uses an image forming mechanism based on the “**DE BROGLIE WAVELENGTH**” ($\lambda_{\text{deBroglie}} = h/p$) that involves electrons that can probe on molecular level and provide an extremely high spatial resolution better than $0.1 \text{nm} = 10^{-10} \text{m}$ with a magnification of the order of $M_{\text{mag}} = 10^6$; for instance at 10^5V acceleration potential, the de Broglie wavelength of the electrons is $\lambda_{\text{deBroglie}} = 4 \text{pm} = 4 \times 10^{-12} \text{m}$ (see [Figure M.28](#)).

Figure M.28 Example of Magnification, using a magnifying glass.

Magnification, angular

[general] See **ANGULAR MAGNIFICATION**.

Magnitude

[general] Length of vector, **NUMERICAL** value of parameter/tensor, signal strength, or reactivity of chemical reaction.

Magnus, Heinrich Gustav (1802–1870)

[computational, fluid dynamics] Scientist and chemist from Germany. Heinrich Magnus provides a significant insight into the phenomenon of **LIFT** with respect to objects in flight, specifically the deviation from a trajectory for bullets (see [Figure M.29](#)).

Figure M.29 Heinrich Gustav Magnus (1802–1870) in 1841.

Magnus effect

[fluid dynamics] Lift force explained by **HEINRICH GUSTAV MAGNUS** (1802–1870) in 1852. The **LIFT** applies to finned projectiles (wings may be a consideration, but the Magnus effect applies to vortices) as well as to other objects specifically when a form of rotation or **VORTEX** is involved (yawing or spinning projectiles),

such as a ball or bullet, and also applies to a rotating fan. The lift on a ball for instance is a function of the surface area (configuration, SURFACE ROUGHNESS, and size A), geometry (e.g., GOLF BALL), the inherent velocity (v), the orientation of the ball, as well as the rotation and the density of the FLUID medium (ρ). Magnus hypothesized that lift was derived from nonsymmetrical FLOW separation within the BOUNDARY LAYER of the PROJECTILE. The lift force, using a coefficient of lift (C_L), is defined as $F_L = (1/2)C_L\rho Av^2$. The Magnus effect is distinguishably noticeable for large objects, such as a volleyball being struck during a serve, making the ball float and suddenly visibly lift in an unpredictable trajectory (see Figure M.30).

Figure M.30 Representation of the Magnus effect.

Magnus force

[computational, fluid dynamics] Force associated with vortices around a body in a FLOW (see MAGNUS LIFT).

Magnus lift

[fluid dynamics] “Lifting force” acting on rotating PROJECTILE bodies. A rotating body will provide an increase in pressure where the surface MOTION is in the opposite direction of the FLOW (according to Bernoulli’s law) causing disruption of the BOUNDARY LAYER, and lower pressure on the surface area that moves in the same direction as the flow, forming an eddy. The force vector on an object with a boundary layer vortex resulting from external flow conditions is $\vec{F}_{\text{Magnus}} = \kappa_i (\nu_{\text{vortex},i}, -u_{\text{irrotational},i})$, where $\nu_{\text{vortex},i}$ is the vortex flow velocity in the i th segment on the surface and $u_{\text{irrotational},i}$ the irrotational velocity resulting from neighboring vortices (derived from the VORTICITY $\omega_v(\vec{r}, t) = \nabla \times u(\vec{r}, t)$), and κ_i is the VORTEX “strength” of the i th vortex on the surface derived from the BIOT–SAVART LAW. Also known as KUTTA LIFT (see Figure M.31).

Figure M.31 Illustration of Magnus lift, with insert of the lift of a rotating base-ball, thrown by the pitcher.

Maiman, Theodore Harold (1927–2007)

[optics] American physicist, most known for constructing the first operational laser known, where laser is the acronym for light amplification by STIMULATED EMISSION of radiation. The laser made by Maiman was what is referred to as a ruby laser, made with chromium oxide crystal Cr_2O_3 . The invention of the laser is still under dispute between Maiman and GORDON GOULD (1920–2005) (see [Figure M.32](#)).

Figure M.32 Theodore Harold Maiman (1927–2007).

Malus, Étienne Louis (1775–1812)

[general] Physicist from France. In 1808, Étienne Malus, an engineer in Napoleon's army, discovered the POLARIZATION OF LIGHT waves. Malus was one of JEAN BAPTISTE JOSEPH FOURIER'S (1768–1830) pupils at the Ecole Polytechnique in Paris, France (see [Figure M.33](#)).

Figure M.33 Étienne Malus (1775–1812).

Malus's law

[general, optics] The radiance of unpolarized light (Ψ) transmitted through two polarizers on the same optical path with the relative ANGLE of the POLARIZATION direction between the two polarizers Θ expressed as $\Psi = \Psi_0 \cos \Theta$, where the minimum transmission is accomplished when the two polarizers are crossed, with the angle of polarization perpendicular. This was described by ÉTIENNE MALUS (1775–1812) in 1809.

Manhattan project

[atomic, nuclear] Code name for the development of the ATOMIC BOMB headed by Lieutenant General Leslie Richard Groves, Jr. (1896–1970), including the following scientists: NIELS BOHR (1885–1962), JAMES CHADWICK (1891–1974), Otto Frisch (1904–1979), ENRICO FERMI (1901–1954), and RICHARD PHILLIPS FEYNMAN (1918–1988) under the direction of ROBERT OPPENHEIMER (1904–1967) (see [Figure M.34](#)).

Figure M.34 Leader of the Manhattan Project: Lieutenant General Leslie Richard Groves, Jr. (1896–1970). (Courtesy of the US Department of Energy.)

Manning, Robert (1816–1897)

[fluid dynamics] Scientist and engineer from Ireland. Manning is known for his contributions to FLOW descriptions in rivers and canals (see [Figure M.35](#)).

Figure M.35 Robert Manning (1816–1897).

Manning equation, open channel

[fluid dynamics] Open channel flow description introduced by ROBERT MANNING (1816–1897) in 1889 as an alternative to the Chezy equation. The Manning equation defines the FLOW (Q) as a function of flow area (A), the slope of the bottom of the channel (S_{slope}), as well as the ROUGHNESS of the walls and bottom (defined by the Manning roughness coefficient M_R listed in tables for various configurations), and the flow velocity as v : $Q = (1/M_R)AR_H^{2/3}\sqrt{S_{\text{slope}}}$, with R_H the hydraulic radius (the ratio of the cross-sectional area of flow to the perimeter of the wetted area, that is, the combined length of all the borders that are touching the LIQUID) (see Figure M.36).

Figure M.36 (a–c) Examples of the implications of the Manning equation, based on simulations produced by The COMET® Program. (Courtesy of the University Corporation for Atmospheric Research (UCAR), and National Oceanic and Atmospheric Administration (NOAA), https://www.meted.ucar.edu/about_legal.php.)

Manometer

[fluid dynamics, general] Device designed to measure volumetric PRESSURE (P).

Pressure gauge

Used as a dial meter or as a liquid column. The height of a column (h) of LIQUID provides generally the mechanism of action to establish the pressure based on COMMUNICATING VESSELS transferring the force applied by pressure on a surface area (A) into a gravitational force (GRAVITATIONAL ACCELERATION g) of a cylinder of a liquid with mass $m = \rho V = \rho Ab$, with density ρ , eliminating the surface area to accommodate for pressure using $F = PA = mgb$, or $P = \rho gb$. A special manometer is used for the determination of BLOOD PRESSURE. An arm band is inflated by pumping AIR into a cuff and the cuff pressure is measured with a mercury (Hg) column in mm Hg. Blood pressure is used to check for arteriosclerosis and deviations in the

pump function of the HEART itself. The pressure in the blood vessels (artery in the elbow of the arm) is measured by listening for blood seeping through the constricted vessel as it opens up when the pressure in the cuff is slowly released. The sounds in the periodic FLOW pattern are referred to as KOROTKOFF SOUNDS. The arm pressure is roughly equal to the pressure at the heart since it is at level altitude, any deviation in height needs to be corrected for by the Bernoulli equation (see [Figure M.37](#)).

Figure M.37 Liquid-column Manometer.

Marangoni, Carlo Giuseppe Matteo (1840–1925)

[fluid dynamics, general] Scientist from Italy. Marangoni provided research on the effects on SURFACE TENSION due to spatial variations in a BUBBLE shape (e.g., pear, donut, and sphere) in 1865. The tangential (shear) forces at the surface due to influences from wind on a falling droplet or material inhomogeneities (e.g., dissolved chemicals) as well as temperature effects are referred to as Marangoni forces. One expression of a Marangoni surface tension force for a bubble (e.g., soap bubble) is the tangential force (T_s) as a function of the bubble WALL thickness (SKIN thickness τ_d) and local bubble layer density (ρ_s) as a function of the polar ANGLE (θ) with the reference frame at the “center” of the bubble with average radius R_0 (which may not be spherical), as a function of location in the reference frame ($\vec{r}$) expressed as $dT_s/d\theta = -(1/2)\rho_s(\vec{r})R_0\tau_d(r)g\sin\theta$, where g is the GRAVITATIONAL ACCELERATION. Note that the skin of the bubble has two surfaces where forces are acting (see [Figure M.38](#)).

Figure M.38 Carlo Giuseppe Matteo Marangoni (1840–1925).

Marcacci, Arturo (late 1800–early 1900)

[biomedical, optics] Scientist from Italy. Arturo Marcacci used his discovery of the toxicity of cinchonamine and quinine (generally alkaloids) in animal and plant cells when exposed to light to perform the first recorded photochemical procedure in BIOMEDICAL OPTICS in 1888.

Marconi, Guglielmo (1874–1937)

[electronics] Italian physicist. Marconi is best known for the development of the first operational RADIO transmitter in 1895. Based on his work in Great Britain, Marconi provided radio transmission between England and France in 1899, and had a company called the Wireless Telegraph and Signal Company, now named the Marconi Company, Ltd. (see [Figure M.39](#)).

Figure M.39 Guglielmo Marconi (1874–1937).

Maricourt, Pierre de (1220–1290)

[general] A.k.a. Petri Pergrinus, scientist from France who used needles made of MAGNETIC material to map out the patterns of MAGNETIC FIELD lines of naturally occurring magnetic materials. However, naturally occurring MAGNETISM (i.e., PERMANENT MAGNET) was supposedly already known in or before the tenth century before Christ (1000 BC) in our calendar. The MAGNET was named after the city in Greece called Magnesia where iron oxide was mined and its magnetic properties discovered. The official development of the compass is attributed to WILLIAM GILBERT (1540–1603) (see [Figure M.40](#)).

Figure M.40 Statue of Pierre de Maricourt (1220–1290).

Marine geophysics

[general, geophysics] *See* **HYDROLOGY**.

Mariner

[astrophysics/astronomy, general] Several spaceships launched from 1962 to 1972 by the United States; Mariner-2: 1962, trip to VENUS; Mariner-2: 1964, trip to Mars; Mariner-5: 1967 close range fly-by of Venus; Mariner-6 and 7: 1969, trip to the MARS polar regions; Mariner-9: 1971, orbit around Mars; Mariner-10: 1973–1975, trip to Mercury. The Mariner spacecraft series was followed by the Viking series in the 1970s (see [Figure M.41](#)).

Figure M.41 Spaceship mariner, Mariner-9 launched in 1971. (Courtesy of the National Aeronautics and Space Administration [NASA].)

Mariner

[geophysics] Nautical entrepreneur, sailor. Person associated with marine life in respect of traversing the globe on the water.

Mariner's astrolabe

[computational, general, geophysics] Instrument used by sailors in the seventeenth century for navigation at sea. The Mariner's astrolabe measures the altitude of the Sun as a function of the time of day to derive the

location of the vessel. The Mariner's astrolabe was developed by the Portuguese. The Mariner's astrolabe was replaced by the SEXTANT in the late seventeenth century (see [Figure M.42](#)).

Figure M.42 Mariner's astrolabe.

Markov, Andrey Andreyevich (1856–1922)

[computational] Mathematician from Russia (see [Figure M.43](#)).

Figure M.43 Andrey Andreyevich Markov (1856–1922).

Markov chain

[computational, thermodynamics] Mathematical process that is subject to changes due to changes in boundary conditions or changes in state, primarily based on statistical PROBABILITY and sequence (next state is the direct result of the previous state). The mathematical system is named after the Russian mathematician ANDREY ANDREYEVICH MARKOV (1856–1922). The Markov chain applies in particular to Monte Carlo methods and simulations in computational PHYSICS.

Markov chain mixing time

[computational, thermodynamics] The rate of convergence to a stationary process with respect to a finite MARKOV CHAIN. The mixing time is typically defined as the initial time frame (τ) over which the process distribution falls below a threshold that is small enough to result in a negligible error in the calculation (acceptable to the process), such as $1/e^2$ measured in “DISTANCE” or the MAGNITUDE between the sequential distributions Θ^1 (and more generally, Θ^p for a mixed system) at time τ and the stationary distribution.

Markov process

[computational, thermodynamics] See MARKOV CHAIN.

Mars

[astrophysics/astronomy, general, geophysics] Fourth planet from the Sun in the Earth’s SOLAR SYSTEM at a DISTANCE of 2.491×10^{11} m at its greatest distance (oval orbit, *also see* KEPLER). Mars has an equatorial diameter of 6794×10^3 m. The axial rotation of Mars is on average 24 h 37 min and 22.6 s, the revolution around the Sun is 686.980 earthdays. The PLANET Mars is also known as the “Red Planet” due to its colored appearance resulting from blowing red-dust clouds. Mars was visited by the US NASA program spacecraft, the Pathfinder, in 1997, next to a passing visit of the Mariners series and the Viking series of spacecrafts (see [Figure M.44](#)).

Figure M.44 The planet Mars.

Marsden, Ernest (1889–1970)

[atomic, nuclear] Scientist from the United Kingdom. Coworker of JOHANNES GEIGER (1882–1945) and contemporary and colleague of ERNEST RUTHERFORD (1871–1937) who worked on experimental determination of the ENERGY content of ALPHA PARTICLES around 1910. The experiment used thin METAL foils bombarded by alpha particles to observe the SCATTERING pattern, and most alpha particles went straight through, indicating their size

to be smaller than the LATTICE structure of the atoms in the foil. The backscattered alpha particles had to encounter same charge particles with a greater mass, later discovered as the NUCLEUS. (*Note:* the charge of the alpha particle was at the time known to be twice that of the electron and positive.) Based on the experimental observations of Marsden and Geiger, Rutherford proposed his model for the atomic nucleus in 1911 (see [Figure M.45](#)).

Figure M.45 Ernest Marsden (1889–1970) in 1921.

Marshak, Robert Eugene (1916–1992)

[atomic, computational, nuclear] Physicist from the United States. Marshak developed a theoretical description of the development and evolution of shock waves under the conditions of extremely high temperatures. One specific application of this field of research is in a nuclear explosion. The shock waves generated as the result of an ATOMIC BOMB are called “Marshak waves.” This explanation was the subject of a renewed interest a few years ago because it helped describe the consequences of a SUPERNOVA explosion. During his time at Los Alamos, Marshak worked with a select renowned group of physicists such as HANS ALBRECHT BETHE (1906–2005), NIELS BOHR (1885–1962), ENRICO FERMI (1901–1954), RICHARD PHILLIPS FEYNMAN (1918–1988), and ROBERT OPPENHEIMER (1904–1967) (see [Figure M.46](#)).

Figure M.46 Robert Eugene Marshak (1916–1992). (Courtesy of the Los Alamos National Laboratory.)

Marshak wave

[atomic, computational, nuclear] Shock WAVE generated during a nuclear explosion, also referred to as a THERMAL WAVE, or radiation DIFFUSION wave. The theoretical formulation was developed by ROBERT MARSHAK (1916–1992). Nuclear explosions are associated with RADIATION conduction, which is facilitated by photons traveling at the speed of light. The physical bounding velocity of thermal waves is much higher than ordinary explosions facilitating classical kinetic heat conduction, which is restricted by the speed of SOUND. The temperature profile of a thermal wave is markedly different from the GAUSSIAN DISTRIBUTION of linear heat conduction. In a nuclear thermal wave, the temperature in the heated zone is fundamentally constant everywhere radiating out from the source of the explosion, whereas near the front it rapidly drops to zero (see Figure M.47).

Figure M.47 Temperature profile for a Marshak wave.

M

MASER

[atomic, electromagnetism] Device that produces amplified MICROWAVE radiation by means of STIMULATED EMISSION (i.e., RESONANCE) phenomena in the host medium, developed approximately in 1954 by CHARLES HARD TOWNES (1915–2015) and ARTHUR SCHAWLOW (1921–1999) with their team at Columbia University in New York, NY and at the Lebedev Institute in Moscow by Nicolay G. Basov (1922–2001) and Aleksandr M. Prokhorov (1916–2002). All four received the Nobel prize for their efforts. Acronym for Microwave Amplification by Stimulation Emission of Radiation. The concept is based on the principle of stimulated emission introduced by ALBERT EINSTEIN (1879–1955) in 1917. Later this concept was found to work at shorter wavelengths using appropriate media, creating the LASER (see Figure M.48).

Figure M.48 (a) outline of the MASER oscillation principles, (b) Sealed glass tube used to confine a discharge in hydrogen at radio frequency, representing one of the fundamental elements inside a hydrogen maser. (Courtesy of Smithsonian Astrophysical Observatory; Jet Propulsion Laboratory (JPL)—Frequency Standards Laboratory/ National Aeronautics and Space Administration [NASA].)

Mass (m)

[general, nuclear] Measure of the INERTIA of a volume of substance of media, the physical presence irrespective of GRAVITATIONAL ACCELERATION. The weight of an object on the other hand takes GRAVITY in consideration. Also, the amount of MATTER consisting of atoms and/or (solely) elementary particles. The atomic standard with respect to mass uses the “unified atomic mass unit” u defined as $1\ u = 1/12(^{12}\text{C})$, one-twelfth of the mass of a standard carbon ATOM (^{12}C). Mass operational definition relies on the derived quantity of matter (m) based on the measured weight (force “ F ”) and the known gravitational acceleration (a) at the location of the measurement, leading to the mass by applying NEWTON’S SECOND LAW: $F = ma$.

Mass (mu)

[atomic, nuclear] A unit of mass based on the elementary atomic building blocks, using 1/16 of the mass of an oxygen ATOM, where the oxygen atom has a mass of 16.00000 mu. Abbreviation: mu, also found as “atomic mass unit,” amu.

Mass absorption coefficient

[nuclear] See MASS ATTENUATION COEFFICIENT.

Mass attenuation coefficient (μ/ρ)

[biomedical, energy, nuclear] Measurement of the DECAY in PHOTON stream for an ELEMENT, chemical species, or substance (e.g., SOLUTE) due to annihilation or SCATTERING of ELECTROMAGNETIC RADIATION at a particular wavelength; defined per unit mass (based on density $\rho = m/V$, where m is the mass of the substance with V ; note gaps in the substance will reduce the PROBABILITY of interaction with EM waves and hence reduced density results in lower attenuation) for a single mixture or element.

Mass balance

[thermodynamics] See CONSERVATION OF MASS.

Mass balance equation

[thermodynamics] Expression that states that the quantity of all species in a medium (solid, LIQUID, and SOLUTION) containing a particular ATOM (in stable or ionized state or bound as molecules or group of atoms) must equal the quantity of that constituent (e.g., ions or group of atoms: molecules) that has been delivered to the medium. This can be expressed in moles or grams. In a chemical reaction, the mass balance equation defines the quantities of the species involved in the reaction, for instance $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O} \rightleftharpoons 2\text{H}^+ + 2\text{OH}^-$.

Mass balance for a work, heat, and bulk-flow process

[thermodynamics] Kinetic process with respect to the relative MOTION of chemical constituents of various species with respect to each other (i.e., separation and mixing processes). The end result is driven by concentration gradients, which are represented by the entropy of the imbalance in chemical potential. Fluid flow without mass transfer falls under FLUID mechanics, and is not part of the field of mass transfer. Mass transfer theory closely resembles HEAT TRANSFER, as described by the pioneering work of Lewis and Whitman in 1924. The mass transfer in analogy uses a mass transfer coefficient h_m , equivalent to the thermal convection coefficient h . DIFFUSION theory may only be applied for molecular mixtures; PARTICLE size ($d < 10^{-8}\ m$). Under colloid solutions and suspensions (particle size ranging: $10^{-8}\ m < d < 10^{-5}\ m$) the Brownian theory applies. For larger particles ($d > 10^{-5}\ m$), the movement/migration is described by NEWTONIAN MECHANICS. Rewriting Fick’s law for mass diffusion (without phase changes or chemical reactions), this provides for the constituent i : $(\partial \rho_i / \partial t) + \nabla \cdot (\rho_i \vec{v} + \rho_i \vec{v}_{di}) = (\partial \rho_i / \partial t) + \nabla \cdot (\rho_i \vec{v}) - D_i \nabla^2 \rho_i \vec{v} + \rho_i \vec{v}_{di} = \vec{w}_i$, where ρ_i is the density

of the respective species (in the thermodynamic equivalent the density can be replaced by a temperature parameter), $\vec{v}_{d,i}$ the diffusion velocity for constituent i , $\vec{v}$ the convection velocity, D_i the respective DIFFUSIVITY for the constituents ($[(dn_{di}/dt)/A]\vec{n} = -D_i\nabla c_i$, where n_{di} is the mass diffusion FLUX of species i , A the cross-sectional area of mass transfer, c_i the respective concentrations for the chemical constituents [mol/m^3], and $\vec{n}$ the normal to the surface area), and $\vec{w}_i$ the FLOW rate (particle flux).

Mass damper

[general, mechanics] Dampening pod attached to a moving mass, for example a SHOCK ABSORBER. Also known as a “harmonic absorber,” based on the capacity of changing the AMPLITUDE and RESONANCE FREQUENCY of a FORCED OSCILLATION. The mass damper usually includes a spring for ENERGY conversion purposes. The damper is usually attached to a solid structure to reduce the dynamic response of the oscillating structure. The frequency of the damper can be tuned to a particular oscillation frequency to optimize the dampening efficiency. Tuning to specific structural frequency can be accomplished by the FRICTION forces applied within the dampener as well as the spring constant. Dampening can be accomplished by means of FLOW constraints of a liquid filled piston system or by means of surface contact friction. Mass dampers are used in tall buildings, especially in earthquake-prone zone, to reduce the vibrations from wind and tremors and preserve the integrity of the structure (see Figure M.49).

Figure M.49 (a) Tuned Mass damper in sky-scraper in Taipei; Taipei 101 and (b) detail of the Taipei AMss damper. (Courtesy of Guillaume Paumier.)

Mass defect

[chemical, general, nuclear] In chemical and atomic systems this relates to the mass change in bound systems (primarily decrease), particularly with respect to atomic nuclei. The mass nuclear defect can be expressed as $\Delta m = Z(m_p + m_e) + (A - Z)m_n - m_{\text{atom}}$, where m_{atom} is the mass of the primary nuclide, A the mass number (representing the number of nucleons), Z the atomic number (representing the number of protons), m_p , m_e , and m_n , respectively the PROTON, electron, and NEUTRON mass.

Mass density (ρ)

[solid-state] MASS (m) per unit volume (V): $\rho = m/V$, also DENSITY.

Mass energy

[nuclear] Concept that the MASS (m) of an object or system has an ENERGY (E) equivalent: $E = mc^2$, where $c = 2.99792458 \times 10^8$ m/s is the speed of light. Additionally, adding for instance 180 megajoules (180 MJ) of a variety of energy formats to an object will increase the mass by 2 μ g. Conversely, mass can be converted into energy, such as with the ATOMIC BOMB or nuclear power generators.

Mass energy absorption coefficient

[biomedical, energy, thermodynamics] The X-RAY energy (keV–MeV range) absorbed per unit mass as described in RADIATION THERAPY treatment, also referred to as mass–energy attenuation (μ_{en}/ρ). The mass–energy attenuation coefficient cannot directly be derived; however, it relies on the theoretical conversion with respect to the mass attenuation coefficient provided by an efficiency factor f_s ; after Stephen M. Selzer (1940?–) who provided the heuristic proof of the relationship between the radiation MASS ATTENUATION COEFFICIENT (μ/ρ) and the MASS ENERGY transfer coefficient (μ_{tr}/ρ): $\mu_{\text{en}}/\rho = (\mu_{\text{tr}}/\rho)(1 - g_r) = f_s (\mu/\rho)(1 - g_r)$, where the average ratio of kinetic energy of particles ionized during radiation interaction and lost due to deceleration with inherent emission of PHOTON (i.e., radiative DECAY) is represented by g_r .

Mass excess

[nuclear] Expression of the BINDING ENERGY between nuclides (i.e., NUCLEAR BINDING ENERGY), in relative measure to the binding energy within the carbon-12 ATOM characterized per nucleon. In a nuclide, this represents the difference between the actual mass of the nuclide with respect to the mass number expressed in atomic mass units.

Mass flux

[general] The FLOW rate of mass per unit area. The following symbols are used in different fields of science and ENGINEERING: ϕ , Φ , j , J . One specific example is the current density (electron flow rate per cross-sectional area, but as positive particles) often shown as j or J .

Mass number (A)

[atomic, chemical, general, nuclear, solid-state] The number of nucleons in the NUCLEUS of an ATOM. Symbol: A .

Mass of the neutron

[nuclear] Neutral charge nuclide with mass $m_p = 1.674929 \times 10^{-27}$ kg = 1.00866 u.

Mass spectrograph

[atomic, general, solid-state] See MASS SPECTROMETER and MAGNETIC SPECTROMETER.

Mass spectrometer

[atomic, general, solid-state] Device used to separate accelerated ions with respect to their respective CHARGE (q) to MASS (m) ratio: q/m . Charges are first accelerated under an applied electric field (E as the result of a POTENTIAL DIFFERENCE over a fixed DISTANCE, providing a Coulomb force $F_{\text{Coulomb}} = qE$) and are next sent through a velocity (v) filter (based on sending accelerated ions through a MAGNETIC FIELD (B); $qE = qvB$, yielding: $v = E/B$) that provides a uniform velocity profile, irrespective of charge or mass. The ions with specific mass (m) and CHARGE (q) will be diverted by means of an external uniform magnetic field (B_0), providing a radius of curvature ($R_{\text{Mass-Spec}}$) of the circular trajectory under the right-hand rule resulting from the magnetic force $F_{\text{mag}} = q\vec{v} \times \vec{B}$: $q/m = E / BB_0 R_{\text{Mass-Spec}}$. Generally the ions have a single charge (positive or negative; $q = |e| = 1.60217657 \times 10^{-19}$ C), but not necessarily. The spectroscopic position of the detection plate (including the detector slit configuration, “mechanically” providing a final filtration mechanism) for the

respective particles with respect to the undeflected ION is $\Delta y = -a_1(\Delta(mv^2)/m_0v_0^2) + a_2(\Delta(mv)/m_0v_0)$, where $m = m_0 + \Delta m$, $v = v_0 + \Delta v$, and a_1 and a_2 are characteristic constants with respect to the design and functionality of the mass spectroscopy instrument.

Mass spectroscopy

[atomic, biomedical, solid-state] Detailed measurement of the MASS (m) of isotopes by a device (MASS SPECTROGRAPH or mass spectrometer) introduced by Francis William Aston (1877–1945) in 1919. Charged particles are performing a curved trajectory with radius depending on their charge and mass. The deflection is based on $qE = mv^2/2$, CONSERVATION OF ENERGY, where q is the net ISOTOPE charge, E is the applied electric field, and v is the achieved velocity of the accelerated PARTICLE under the influence of the force. A MAGNETIC deflector separates the particles based on their trajectory and are sent through slits, providing a discrete location of the various isotopes with respective masses. The RESOLVING POWER of the device is defined by the design and the focusing ability of the spectrometer (see Figure M.50).

Figure M.50 Mass spectroscopy.

Mass–spring system

[acoustics, biomedical, general, mechanics, nuclear] {use: energy conversion, actuation, imaging} There are many mass–spring systems, some even damped. To name but a few: shock absorbers on an automobile, woofer (loud SPEAKER), gong/bell, tooth brush, and many more. Generally a simple mass–spring system obeys FICK'S LAW. A damped mass–spring system uses some form of COMPLIANCE with a phenomenological constant identifying the level of “RESISTANCE” ($C_{\text{Compliance}}$) to dampen the MOTION. Examples of damped motion are shock absorbers, woofer loud speaker cone, and keys on a PIANO. Several motions are repetitive with a constant frequency and are considered damped OSCILLATIONS, other movements are single pulse. All motions rely on an external force or driving mechanism to initiate the motion. The force

expression for a damped spring motion is $F = F_{\text{external}} - C_{\text{compliance}}v - kx = ma$, where v is the VELOCITY of the mass. The external force resulting from a blow (SHOCK ABSORBER or piano) is the change in MOMENTUM P_m : $F_{\text{external}} = (dP_m/dt) = m(dv/dt)$, or it can be a driving mechanism based on ELECTRICITY or MAGNETISM with a preset frequency (e.g., VOICE COIL), another application is in ULTRASOUND imaging using piezoelectric or other mechanisms of driving the OSCILLATION (*also see* OSCILLATION) (see [Figure M.51](#)).

Figure M.51 Mass-spring system that is, loud speaker.

Mass transfer Biot number (Bi_{mass})

[fluid dynamics] Ratio of diffusive to reactive, respectively convective mass transfer resistance:

$Bi_{\text{mass}} = k_f L / D_{\text{solid}} = h_D L / D_{\text{solid}}$, where k_{fb} is the THERMAL CONDUCTIVITY, D_{solid} is the DIFFUSION coefficient, L is the characteristic length, and h_D the mass-transfer coefficient. The Biot mass transfer number determines the uniformity of constituent concentration in solids.

Mass transfer Fourier number

[thermodynamics] See **FOURIER NUMBER**, **MASS TRANSFER**.

Mass transformation equation

[atomic] Relativistic MASS (m) of an object traveling with velocity v in the observer's frame:

$m = m_0 \left(1 / \sqrt{1 - (v^2/c^2)} \right)$, where $c = 2.99792458 \times 10^8$ m/s is the speed of light in vacuum and m_0 is the REST MASS (classical mechanics). The coefficient $\left(1 / \sqrt{1 - (v^2/c^2)} \right)$ is defined as the mass transfer coefficient.

Mass absorption coefficient

Massieu, François Jacques Dominique (1832–1896)

[thermodynamics] Scientist and engineer from France. Massieu is known both for his introduction of the “characteristic function” of a FLUID body, the MASSIEU FUNCTION, and the initial thermodynamic concept of the MASSIEU POTENTIAL, defining the free entropy of a system (see [Figure M.52](#)).

Figure M.52 François Jacques Dominique Massieu (1832–1896).

Massieu function

[thermodynamics] Description of the entropy of a system based on a coordinate system with a number (n) of axes {cumulative: (x_i, y_j) } that correlate to the respective variables of the system: $[\Psi] = \Psi(X_1, X_1, \dots, X_i, Y_{i+1}, \dots, Y_n)$, introduced in 1869 by FRANÇOIS MASSIEU (1832–1896) (see MASSIEU POTENTIAL).

Massieu potential

[thermodynamics] Entropic thermodynamic potential defined as $\Phi = S - (1/T)U$, where $S = (U/T) + (PV/T) + \sum_{i=1}^n (-\mu_i(N_i/T))$ represents the entropy of a system, T the temperature, U the internal ENERGY, P pressure, V the volume of the system, μ_i the chemical potential chemical constituent i , and N_i the quantity of items (particles, atoms, ions, etc. expressed in MOLE) of chemical component i . The concept of free entropy as introduced by FRANÇOIS MASSIEU (1832–1896) in 1869. The Massieu potential and free energy predate the Gibbs's free energy, which was introduced in 1875 by JOSIAH WILLARD GIBBS (1839–1903). It was shown that the free entropy follows from the LEGENDRE TRANSFORM of the true entropy of a system or process. The Massieu potential is based on the fact that the state of a body is completely defined when two of the three parameters that represent the volume of the system, the temperature of the system, as well as the pressure on its surface are known. Also known as Helmholtz free entropy.

Material fatigue

[general, mechanics] Localized gradual structural damage to a composite or metallic structure or material resulting from cyclic or infrequent repetitive loading. The FATIGUE results from applied nominal maximum stress below the ultimate TENSILE STRESS of the material, and generally less than the yield stress limit. When a certain stress threshold is exceeded, on a MICROSCOPIC level, certain threshold, cracks will form, weakening the

integrity of the structure on a macroscopic scale. The continued exposure to the forces involving the implementation of material fatigue will eventually result in breakage (*also see* METAL FATIGUE) (see [Figure M.53](#)).

Figure M.53 The impact of Material Fatigue on the structural integrity of the Tacoma Narrows Bridge in 1940, constructed of metal, concrete, and asphalt. The bridge was destroyed only weeks after the official opening due to the vibrations on the suspension cable (Aeolian sound wave) providing the resonance frequency of the road-surface section aspect of the bridge with the associated natural frequency based on elastic moduli, characteristic lengths, and persistence in driving wind (direction and magnitude).

Matter

[general, nuclear, solid-state] Compilation of the physical properties of a medium that define its response to external influences, specifically force. Matter is congealed from a mixture of ELEMENTS for which the atoms and molecules are held together by short- and long-range forces such as gravitational attraction and van der Waals attraction. Matter can be found in various states, or phases: GAS/VAPOR, LIQUID, solid and PLASMA. Mass is a quantity of MATTER, one of the fundamental dimensions, next to thermal properties and volume (incorporating the dimensions of all directions within the frame of reference), and hence density. The thermal properties are internal ENERGY and heat, next to the SPECIFIC HEAT with respect to phase transfers, the change of phase and the pattern in which this takes place, heat exchange with neighboring bodies, conduction, convection, and radiation next to THERMAL EXPANSION. Additional mechanical properties of

matter are deformation, COMPLIANCE, and MOMENT OF INERTIA, depending on the mass distribution and applicable LATTICE and/or crystalline structure (see [Figure M.54](#)).

Figure M.54 Matter concepts.

Matter wave

M

[acoustics, general] Wave propagation based on mechanical disturbance of particles in a medium. Also referred to as a MECHANICAL WAVE, primarily pertaining to ACOUSTICS and FLOW (crest of waves on beach). The VIBRATION of a string on an instrument is a transverse matter wave, and the SOUND of a VOICE in AIR is a longitudinal matter wave (*also see* **DE BROGLIE**) (see [Figure M.55](#)).

Figure M.55 Matter wave in flag.

Maupertuis, Pierre Louis Moreau de {Pierre Louis Moreau de Maupertuis} (1698–1759)

[computational, general] French mathematician and physicist. Maupertuis formulated the rudimentary principle of the path of least RESISTANCE to CONSERVE ENERGY (see Figure M.56).

Figure M.56 Pierre Louis Moreau de Maupertuis (1698–1759).

Maupertuis principle

[computational, general] Integral equation describing the path of a PARTICLE in MOTION, following the path of “least action,” that is, path of least RESISTANCE; introduced by PIERRE LOUIS MOREAU DE MAUPERTUIS (1698–1759). The integral defines the condition of the extremum (maximum, minimum, saddle point, or stationary point) for a system with N generalized coordinates $\vec{\chi} = (\chi_1, \chi_2, \dots, \chi_N)$ between two states referenced as χ_1 and χ_2 , both as a function of location, conditions (outlined by the conjugate momenta at the generalized coordinates of the system: $\vec{p} = (p_1, p_2, \dots, p_N)$) and TIME (t) by means of the action functional using the path as a function to define the location of the extremum, that is, the condition of the function describing the system: $S_0[\vec{q}(t)] \stackrel{\text{def}}{=} \int \vec{p} \cdot d\vec{q}$ which yields a SCALAR as a solution, where $p_i \stackrel{\text{def}}{=} [\partial L(\vec{\chi}, \vec{\dot{\chi}}, t)] / \partial \dot{\chi}_i$, $L(\vec{\chi}, \vec{\dot{\chi}}, t)$ the Lagrangian of the system, describing the first-order perturbations of the system. The perturbation does generally not exceed the second-order changes in the “path” $S_0[\vec{q}(t)]$.

Maximum occupation number

[high-energy, quantum, solid-state] Ground-state ENERGY EIGENVALUE configurations per unit volume for a FERMION collective in a medium (i.e., condensate) consisting of millions of atoms. The primary difference between fermions and bosons is that fermionic energy states have a maximum occupation number of 1. Bosons, on the other hand, in theory have unlimited occupation states. The Pauli principle for the constituent fermions would practically limit the BOSON occupation number. The maximum occupation number is

expected to be proportional to the “volume” available to the bosons, divided by the volume occupied by the number of fermions constructing one boson (see [Figure M.57](#)).

Figure M.57 The maximum occupation number is outlined by the contour of the actual occupation numbers (n_k) (dotted line) in the excitation band of fermions excited (“pre-heated”) to $\lambda\phi^4$ –inflation (ϕ the oscillation) at resonance under the condition $q \equiv (h^*/\lambda) = 1$, λ the oscillation wavelength. The boundary conditions are defined by the Fermi sphere with radius $\kappa_F = q^{1/4}m_\phi$, m_ϕ the inflation mass of the system, $q = h^{*2}\phi_0/m_\phi^2$, h^* the coupling between the inflation and the fermions (Yukawa type—coupling) and ϕ_0 the amplitude of the inflation oscillation. The resonance in this case has 10 background oscillations.

M

Maxwell, James Clerk (1831–1879)

[electromagnetism, general] Scottish scientist and physicist who developed a rigorous relationship between changing MAGNETIC phenomena and the resulting varying electric manifestations such as the induced electromotive force electric potential in a closed circuit, or an alternating electric field in a more general concept. The work of Maxwell was based on the efforts by the American scholar JOSEPH HENRY (1797–1878), the English scientist MICHAEL FARADAY (1791–1867), as well as inspired by CHARLES WHEATSTONE, WILLIAM THOMSON (i.e., Lord Kelvin), the work by CARL FRIEDRICH GAUSS (1777–1855), and ANDRÉ MARIE AMPÈRE’S (1775–1836) circuital law, compiled shortly after his graduation from the University of Cambridge in 1854 (see [Figure M.58](#)).

Figure M.58 James Clerk Maxwell (1831–1879).

Maxwell equations

[energy, optics] philosophical extension of the concepts of Faraday's law pertaining to the interaction of a varying MAGNETIC FIELD and the ensuing alternating electric field and, when appropriated, the associated electromotive force. In the 1820s, the efforts of both the English scientist MICHAEL FARADAY (1791–1867) and the American scholar JOSEPH HENRY (1797–1878) independent of each other provided the theoretical support for JAMES MAXWELL CLERK (1831–1879) to develop theoretical expressions linking magnetic field variations to electric field changes developing several theories of electromagnetic WAVE propagation and in the process underwriting the propagation of electromagnetic waves at the speed of light. The Maxwell equations are the following:

ORIGIN	DIFFERENTIAL EQUATIONS IN VACUUM	INTEGRAL EQUATIONS IN VACUUM
Gauss's law	$\nabla \cdot \vec{E} = 4\pi\rho_e$	$\oint_S \vec{E} \cdot \vec{n} dA = -4\pi \oint_V \rho_e d^3r = Q_{in}/\epsilon_0$
Gauss's law for magnetism	$\nabla \cdot \vec{B} = 0$	$\oint_S \vec{B} \cdot \vec{n} dA = 0$
Faraday's law	$\nabla \times \vec{E} = \partial \vec{B} / \partial t$ $\partial \vec{E} / \partial z = 0$	$\oint_S \vec{E} \cdot \vec{n} d\ell = -(1/c)(\partial / \partial t) \oint_V \vec{B} \cdot \vec{n} dA$
Ampère's law	$\nabla \times \vec{B} = \epsilon_0 \mu_0 (\partial \vec{E} / \partial t)$ $= \nabla \times \vec{B} - (1/c^2)(\partial \vec{E} / \partial t)$ $= (4\pi/c) \vec{J}$	$\oint_S \vec{B} d\ell = -\oint_V \left((4\pi/c) \vec{J} + (1/c)(\partial \vec{E} / \partial t) \right) \cdot \vec{n} dA$

Where $\vec{E}$ is the electric field, ρ_e the charge density per unit volume V , t is time, $\vec{J}$ is the current density, $c = \sqrt{\epsilon_0 \mu_0}$ the speed of light, $\vec{n}$ the normal to the surface A of the enclosed space, S the perimeter of the enclosed surface, ℓ the length of the loop enclosing the charges, respectively, $d\ell$ the segment of the tangent length to the curve of the loop, r the radius of the loop, $\mu_0 = 1.2566 \times 10^{-6} (\text{Wb/A.m}) (\text{N/A}^2)$ the DIELECTRIC permeability for VACUUM, $\epsilon_0 = 8.8541878 \times 10^{-12} (\text{C}^2/\text{Nm}^2)$ the dielectric permittivity for vacuum, Q_{in} the enclosed net total charge, ϵ_0 the dielectric permittivity of vacuum, and $\nabla = \partial / \partial x_i$ is the Laplace operator with respect to all DEGREES OF FREEDOM x_i . Analogously for a magnetic field ($\vec{B}$), the ELECTROMAGNETIC FIELD parameters are related by the Lorentz force on a moving point charge q : $F_\ell = q(\vec{E} + (v/c) \times \vec{B})$, with v the velocity of the moving charges. The current density is connected to the charge change rate as $(\partial \rho_e / \partial t) + \nabla \cdot \vec{J} = 0$.

Maxwell–Boltzmann distribution ($f(X)$)

[fluid dynamics, general, mechanics] Distribution of physical property (e.g., velocity and ENERGY) based on the theoretical work by JAMES CLERK MAXWELL (1831–1879) and LUDWIG EDUARD BOLTZMANN (1844–1906) defined as follows. For the Maxwell energy distribution $N_i/N = g_i e^{-(E_i/k_b T)} / \sum_j g_j e^{-(E_j/k_b T)}$,

where i represents a specific MICROSTATE (e.g., QUANTUM STATE), E_i represents the energy of a specific isolated microstate, T the temperature, $k_b = 1.3806488 \times 10^{-23} \text{ m}^2\text{kg/s}^2\text{K}$ is the BOLTZMANN CONSTANT, g_i a factor that defines the number of microstates with the same energy (DEGENERACY factor), N_i the number of molecules in one equilibrium microstate, and N the total number of molecules this yields: $f(E)dE = 2(1/k_b T)^{3/2} \sqrt{(E/\pi)} e^{-(E/k_b T)} dE$. For the momentum ($p = mv$) (i.e., velocity) this writes as $N_i/N = g_i e^{-((p_{i,x}^2 + p_{i,y}^2 + p_{i,z}^2)/2mk_b T)} / \sum_j g_j e^{-(E_j/k_b T)} = (1/Z) \exp[-((p_{i,x}^2 + p_{i,y}^2 + p_{i,z}^2)/2mk_b T)]$ where m is the molecular mass for the respective constituent of the gas with distribution function $f(p)dp = (1/(2\pi mk_b T))^{3/2} e^{-((p_x^2 + p_y^2 + p_z^2)/2mk_b T)} dp$ (see Figure M.59).

Figure M.59 Outline of the Maxwell–Boltzmann distribution.

Mayer, Julius Robert von {Julius Robert von Mayer} (1814–1878)

[general, nuclear, thermodynamics] Physicist and physician from Germany, pioneer in thermodynamic relations (see VON MAYER, JULIUS ROBERT) (see Figure M.60).

Figure M.60 Julius Robert von Mayer (1814–1878).

Mayer, Maria Goeppert (Göppert) (1906–1972)

[atomic, computational, general, nuclear] Mathematician, scientist, and physicist from Germany at the time, now Poland. Maria Goeppert-Mayer provided pivotal elaborations on the BOHR ATOMIC MODEL for which she received the Nobel prize in 1963. Maria's contemporaries and friends included her teacher MAX BORN (1882–1970) and friend NIELS BOHR (1885–1962). Additional work of Maria included uranium ISOTOPE separation during the Second World War. Also known as Goeppert-Mayer, Maria (see [Figure M.61](#)).

Figure M.61 Maria Goeppert-Mayer (1906–1972).

Mayer relation

[nuclear, thermodynamics] Correlation between the SPECIFIC HEAT under constant pressure (c_p) to that under constant volume (c_v), derived by JULIUS ROBERT VON MAYER. The relationship is a function of the coefficient of isothermal compressibility (κ_T) and the coefficient of isobaric expansion (α_p) next to the TEMPERATURE (T) and VOLUME (V) as $c_p = c_v + (T\alpha_p^2 V / \kappa_T)$.

Mclean, Jay (1890–1957)

[biomedical, fluid dynamics] Physician, chemist, and scientist from the United States. The collaborative efforts of Jay McLean and his professor WILLIAM HENRY HOWELL (1860–1945) resulted in the definition of the anticoagulant properties and the clinical and hemodynamic impact of heparin in 1916 (see [Figure M.62](#)).

Figure M.62 Jay McLean (1890–1957). (Courtesy of the US National Library of Medicine; donation by Dr. Brockbank 1956.)

McLennan, John Cunningham, Sir (1867–1935)

[atomic, nuclear] Scientist and physicist from Canada. Colleagues and collaborators John McLennan and Eli Franklin Burton (1879–1948) discovered a new form of RADIOACTIVITY, consisting of man-made radiation (produced in a VACUUM tube with an electron beam, creating metallic origin radioactivity) that had a high-penetration ability and was ionizing in nature in around 1902. Additional pioneering work by Sir McLennan was in the LIQUEFACTION of helium (see [Figure M.63](#)).

Figure M.63 Sir John Cunningham McLennan (1867–1935) in 1935. (Courtesy University of Toronto, Toronto, Canada.)

Mean free path

[atomic, computational, fluid dynamics, mechanics, nuclear, optics] The average DISTANCE of the resultant vector that describes the path that a particle or ENERGY unit (i.e., PHOTON) moves between interactions that alter the vector magnitude and or direction (e.g., collisions): $\delta = \sum_N \ell_i / N$, for a GAS $\text{mfp} = \lambda_{\text{mfp}} = RT / (\sqrt{2}) \pi d^2 N_A P$, $R = 8.3144621(75) \text{ J/Kmol}$ the universal gas constant, T = temperature, d = diameter of vessel/container (i.e., characteristic length), $N_A = 6.02214129(27) \times 10^{23} \text{ mol}^{-1}$ (Avogadro's number), and P the pressure of the gas. Also, the mean distance (i.e., PROBABILITY of the occurrence of traveling this hypothetical distance, expressed by the resultant vector) a photon traverses between optical interactions of either SCATTERING (e.g., atomic resonance) or annihilation (absorption). Abbreviation: mfp, symbol, δ (see Figure M.64).

Figure M.64 Representation of the mean-free-path in multiple interactions.

Mean life (τ_{decay})

[atomic, nuclear] See MEAN LIFETIME.

Mean lifetime (τ)

[general, nuclear] Mathematical average lifetime of the state of an ISOTOPE in a medium consisting of radioactive material. Also, the exponential constant that defines the DECAY of isotope defined as the reciprocal of the decay constant expressed as $\tau_{\text{decay}} = 1/\lambda_{\text{decay}}$, where $dN/dt = -\lambda_{\text{decay}} N$ with N the number of radioactive isotopes, yielding $N(t) = N_0 e^{-t/\tau_{\text{decay}}}$. This expresses the fact that τ_{decay} is the time in which the quantity of isotopes reduces to $e^{-1} = 0.3679$, or 37% (also see HALF-LIFE).

Mean Speed Theorem

[general] See MERTON MEAN SPEED THEOREM.

Mean value of potential over a spherical surface

[computational, electromagnetism, fluid dynamics] In electric applications, this pertains to the surface charge on a spherical CONDUCTOR. Note that the charge will be equally distributed over the surface (S) of the conductor with surface charge density σ_{charge} . The sphere will have a radius $r > 0$. The total charge is defined as $q_{\text{electric}} = A\sigma_{\text{charge}} = 4\pi r^2 \sigma_{\text{charge}}$. Since this is a symmetric condition, the electric field is directly proportional to the DISTANCE to the origin of the sphere R . The electric potential is derived from the Coulomb law: $V(R) = \oint (\sigma_{\text{charge}} / 4\pi\epsilon_0 r') dr'$, where ϵ_0 is the DIELECTRIC permittivity of VACUUM. Additionally GAUSS'S LAW provides $V(R) = q_{\text{electric}} / 4\pi\epsilon_0 R$. Equating the two potentials yields that the potential outside the sphere is equal to the potential at the center of the sphere: $V(R) = q'_{\text{electric}} / 4\pi\epsilon_0 r$, where q'_{electric} is the total enclosed charge, assuming the sphere is the only charged volume in the space under consideration. In FLUID DYNAMICS,

the potential pertains to the VELOCITY POTENTIAL (ϕ_{flow} ; *Note:* $v_x = \partial\phi_{\text{flow}}/\partial x$, etc. and $v_R = \partial\phi_{\text{flow}}/\partial R$) expressed by $M(R) = (1/4\pi r^2) \oint_S \phi_{\text{flow}} dS = (1/4\pi) \oint_0^{4\pi} \phi_{\text{flow}}(r, \omega) d\omega$, where ω represents the SOLID ANGLE over the surface of the sphere. Incompressible fluids can be described as having potential flows that are solutions of the NAVIER–STOKES EQUATIONS. In solving for the potential flows, one can apply the HELMHOLTZ DECOMPOSITION principle, which states that every solution of the NAVIER–STOKES equations can be decompartmentalized in respective rotational parts and irrotational components, each satisfying LAPLACE’S EQUATION. The irrotational part will satisfy the boundary conditions, whereas the rotational velocity will generally not.

Measurement

[general] Acquisition of data pertaining to an event, phenomenon, or object (dimensions, weight, etc.) in relation to establishing the parameters that best describe the occurrence using qualified and calibrated equipment best suited for the determination of the designated parameters.

Mechanical energy

[biomedical, general, mechanics] *See* WORK.

Mechanical wave

[engineering, general, geophysics] Wave produced by the displacement of material. A mechanical wave can be longitudinal, as performed by the compression of AIR in ACOUSTIC WAVES, or by transverse displacement, such as the plucking of a string on a string instrument (e.g., GUITAR, harp, and PIANO). A combination wave with both transverse and longitudinal properties can for instance be an EARTHQUAKE: combination S-wave and P-WAVE. In SEISMOLOGY, SURFACE WAVES are generally shear waves or TRANSVERSE WAVES, whereas in the core shear waves are not feasible and elastic compression is the main mode (see [Figure M.65](#)).

Figure M.65 Mechanical wave in ropes.

Mechanics

[biomedical, energy, engineering, nuclear, mechanics] The study of objects in MOTION. The motion is for instance, but not limited to, VIBRATION of a chime or cymbal, rotation of a curved billiard ball, as well as a spinning top, and the trajectory of a flare.

Mechanoreception

[biomedical, mechanics] Biological sensing mechanism of action that provides the fundamental basis for touching, HEARING, changes in posture, changes in external or internal pressure, and general strain (biting with the jaw, bending a joint, etc.). The mechanoreception takes place on a cellular level. In the mammalian skin, there are four different types of mechanical sensor: Meissner corpuscles, Merkel disks, Pacinian corpuscles, and Ruffini endings. In the EAR, the ORGAN OF CORTI responds to the bending of a hair to produce an ACTION POTENTIAL that is sent to the brain to indicate the observation of a frequency in the cochlea (BASILAR MEMBRANE) in a specific location that is representative of a single wavelength of motion only. The glabrous SKIN with hair has sensors that respond to stretch. Most knowledge about mechanoreceptor ACTIVITY and function is based on the work by Roland S. Johansson (1950–) and Åke Bernhard Vallbo (1933–), both from Sweden, as recent as the late 1970s (see [Figure M.66](#)).

Figure M.66 Examples of mechanoreceptor in human skin.

Mechanosensitive action

[biomedical, chemical, general, thermodynamics] Operation of ION transport mediation in biological cells in response to external influences such as shear, stress, OSMOTIC PRESSURE, GRAVITY, and acoustic MECHANICS. One function in particular, next to sensing of external influences, is the protection of the CELL itself. Sensing the internal cell pressure will result in a pressure regulation mechanism that will ultimately prevent

the cell from bursting. The mechanosensitive action of the cells is mediated by mechanosensitive ion channels (MSCs). These ion channels can currently be subdivided into two groups: (1) responding to fibrous protein and (2) responding to lipid bilayer stress. One measurable effect in response to applied shear and stress in the CELL MEMBRANE is the change in diameter of what is known as the bacterial large mechanosensitive channels (MscL) in the range of 5–6 nm. The Gibbs free ENERGY difference (ΔG) between the open and closed state of the channel (expressed by the cross-sectional area change ΔA) is defined by the lipid bilayer TENSION (T) as $\Delta G = T\Delta A$. Apart from the change in area, there are also changes possible in the shape of the opening, without actual changes to the area. The shape change may provide a preferred vehicle for certain proteins to be transported through the MEMBRANE to act as signaling proteins.

Medicine

[biomedical, electronics, fluid dynamics] Diagnostic and therapeutic modality that uses ENGINEERING and science to either acquire vital signs, produce anatomical and physiological images, or deliver chemical means (therapeutic design for disease treatment), and ENERGY as well as mandates exercise routines to make a best effort in returning the physical condition and vital signs of an individual to established states that are considered within the normal range for a person of a certain AGE, specific sex, and with a general dietary and exercise history, as well as geographical location while also considering potential genetic influences as well as work-place and living condition exposure to the ELEMENTS and foreign materials such as pollution (roughly defined as chemical substances that are not common occurrence or/and have been established as reagents that diminish specific or general levels of physiological, anatomical values, and vital signs). Based on the acquired information, a treatment can be designed to attempt to remove the cause or eliminate the effects of a physical condition, ranging from allergies, fractures, to cancer to the natural phenomenon of childbirth. An additional host of physiological conditions and anatomical conditions are involved in practicing medical science, some are purely chemical in nature based on an imbalance resulting from a broad range of influences, some genetically predetermined, some resulting to exposure to chemicals. Biological systems are integral systems where no single anatomical or physiological aspect stands isolated from all the other activities and conditions in the body and metabolistic activities. Medicine has a long history (dating back thousands of years) that has been influenced by prejudice, lack of diagnostic abilities, as well as generally incomplete information about the physiological integration of contributing factors to a perceived symptom. The multifaceted aspects of engineering (medical device development), drug interaction (chemical design), and psychological integration are only providing major or minor attributes of a complete description for the affliction or the general state of genetic evolution. Even though a broken LEG can be a straightforward cause-and-effect diagnosis with a well-defined treatment modality, the healing

process may not be universal or straightforward (*also see* **BAYESIAN METHODOLOGY**, **BAYES' THEOREM** [i.e., evidence-based medical informatics]) (see [Figure M.67](#)).

Meissner (Meißner), Walther (1882–1974)

[general] Physicist from Germany. Meissner is best known for his superconductor work, in collaboration with Robert Ochsenfeld (1901–1993) (see [Figure M.68](#)).

Figure M.68 Walther Meissner (Meißner) (1882–1974).

Meissner effect {Meißner effect}

[general] The obliteration of the MAGNETIC FIELD inside a superconductor in comparison to a regular conducting medium. Described in 1933 by the German physicists WALTHER MEISSNER (1882–1974) and Robert Ochsenfeld (1901–1993).

Meitner, Lise (1878–1968)

[atomic, nuclear] Physicist from Austria, famous for her contributions to RADIOACTIVITY and the description of the concept of NUCLEAR FISSION with her nephew Otto Robert Frisch (1904–1979) in 1938. Unfortunately Lise Meitner was not awarded the Nobel prize in Physics for her contributions to the work of FISSION, although her colleague OTTO HAHN (1879–1968) was awarded in 1944 (see [Figure M.69](#)).

Figure M.69 (a) Lise Meitner (1878–1968) at the 1933 Solvay conference (Structure et propriétés des noyaux atomiques; Structure and properties of the atomic nucleus, under the leadership of Paul Langevin) on the front row, second from the right. Two other notable female physicists represented at this conference are also shown: Marie Curie (1867–1934) and Irène Joliot-Curie (1897–1956). (b) Lise Meitner providing a lecture at the Catholic University in Washington, DC, USA in 1946.

Melting point

[general, thermodynamics] Phase transition TEMPERATURE (T) from solid to LIQUID at a fixed PRESSURE (P) for a constant VOLUME (V) of medium. Phase transition in the opposing direction is referred to as FUSION. For the melting PHASE TRANSITION, the change in Gibbs free ENERGY is zero: $\Delta G = 0$; this provides the condition during melting defined by the ENTROPY (S) as $\Delta S = \Delta H/T$ at constant temperature with H the enthalpy of the system. Under constant temperature, the melting point will be a function of pressure (volume of a solid is fixed), such as the one observed underneath the blade of an ice skater. The melting point can be lowered by the addition of a CHEMICAL COMPOUND, providing “freezing-point depression.” Lowering the melting point will require a lower temperature under constant pressure to achieve melting; hence a solid can be promoted to melt by spreading for instance SALT on ice, as used on roadways during snow storms or FREEZING rain. The melting point as a function of pressure or volume can be found from the PHASE DIAGRAM plot in a pressure–volume curve (PV diagram), or pressure–temperature curve (PT diagram) (*also see* FREEZING POINT *and* FREEZING) (see Figure M.70).

Figure M.70 Melting ice with water with a thermometer indicating 0°C, the melting point for ice.

Membrane

[biomedical, chemical, general] All cells in biological entities are sealed off by a membrane. The membrane provides various functions, ranging from protection of the cellular content, transportation of nutrients (oxygen) and waste, and communication with neighboring cells, to extending its function to acquiring information about the chemical and mechanical circumstances affecting the CELL. The content of the cell is primarily designed to sustain the cell, and supporting a renewable ENERGY source: ATP (ADENOSINE TRI-PHOSPHATE). The CELL MEMBRANE is a hydrophobic lipid bilayer, repelling the water DIPOLE. Membranes are mostly made up of phospholipids such as amino phospholipids, phosphatidylcholine, phosphatidylglycerol, phosphatidylinositol, and sphingomyelins. The phosphatidylinositol structure provides one polar head and two nonpolar lipid chains, with inherent chemical properties. The cell membrane has specific properties related to chemical BARRIERS, chemical transport, and related electric trans-membrane (electric-) potential. The cell membrane is highly permeable to a large selection of hydrophobic molecules, and in particular to lipid-soluble solutes such as ALCOHOL, next to vitamin A and vitamin E, as well as steroids. In contrast, the permeability of water-soluble or hydrophilic molecules is restricted to mainly small molecules only. The cell membrane maintains a transmembrane potential that is derived from the ION gradients, described by the NERNST EQUATION for the membrane potential. The key ions involved in the chemical potential are POTASSIUM (K^+), sodium (Na^+), and chlorine (Cl^-). In addition to the steady-state potential, the membrane can depolarize as well for an ACTION POTENTIAL that can communicate events to the central nervous system and the commands to the brain or to the muscles and the organs and glands. The DEPOLARIZATION process involves the active and passive transport of the key ions across the membrane by means of ion pumps and

opening and closing of selective pores: gates. One example is the ion selectivity of the KcsA Potassium channel. This ION CHANNEL has the ability to discriminate between K^+ and Na^+ ions, providing a mechanism for K^+ ions to pass through approximately 1000 times more rapidly than Na^+ ions. This channel has an equilibrium diameter of 40 Å, including the channel protein and a small portion of the membrane. The channel has an approximate length of 89 Å, including the length of the channel protein, as well as 30 Å intracellular space and 25 Å extracellular space. The channel protein provides what is known as the sodium–potassium pump as well as mitigating the passive ion conductivity. The potassium pump provides an active mechanism-of-action to restore the intra- and extracellular ion gradients. The electronic formation of the action potential is described by the HODGKIN–HUXLEY EQUATION. Transmembrane proteins that form the ion channels span the width of the lipid bilayer and support many cellular functions. Some of the transmembrane functions include proton transport (i.e., ACTIVE TRANSPORT: proton pump), water transport, but also act as receptors. A large portion of transmembrane sensors are chemical sensors in nature and belong to the seven transmembrane helix (7TM) family. Due to its chemical response, this receptor protein is popular in medication, and better than 50% of therapeutic and recreational drugs target members of this particular family. One specific receptor example is the transmembrane protein BACTERIORHODOPSIN. Bacteriorhodopsin has a segment that is light sensitive and responds with the onset of a process that can lead to an action potential within femtoseconds of being excited by a PHOTON. Note that a full transmembrane potential is required to reach a threshold of chemical imbalance (deviation from the steady state NERNST POTENTIAL) before the action potential sequence takes full effect. The bacteriorhodopsin harvests light energy and is present in the membranes of some halobacteria as well as in the RODS of the EYE. Bacteriorhodopsin converts the light energy to electrostatic energy, which in turn provides the vehicle to transport protons out of the cell (PTR). The resulting proton gradient (H^+) leads to a large pH gradient across the cell membrane. The acidity is then used to create renewable energy in ATP when the cell allows a proton to move back into the cell, by means of another transmembrane protein, ATP synthase. The PROTON transport is linked with the empirical valence bond (EVB), which defines the breaking and forming of associated chemical bonds, in particular the covalent bonding to hydrogen or dissociation of hydrogen. An important point about the EVB model is that the reaction must be carried out both in water and in the protein. For proton transfer (PT) reactions, the change in free energy of the PT can be obtained if one knows the reaction coefficient (pK_a values) of the donor (DH^+) and the protonated acceptor (AH). The Gibbs reaction energy is described as follows in

kcal/mol: $\Delta G_{PT}^w(DH^+ + A^- \rightarrow D + AH)_{\infty} = 1.38(\Delta pK_a^w)$, where ∞ represents the fact that the donor and acceptor are separated by a great DISTANCE (see Figure M.71).

Figure M.71 (a) Illustration of the construction of the membrane of a biological cell and (b) the use of a membrane in water filtration by means of reverse osmosis.

Membrane capacitance

[biomedical, chemical, electronics] Considering a membrane equivalent electronic configuration composed of capacitance (C_m), RESISTANCE (R_i), and CURRENT (I) and voltage (V_{Nernst} , respectively, $\Delta\Phi_m$) sources, the equivalent circuit for a MEMBRANE can be represented by an electronic schematic. The storage of ionic charges on either side of the membrane presents similar concepts as a standard plate CAPACITOR does. This capacitor however is subject to ION leakage and mediated conduction, making the capacitance a time-dependent phenomenon. The cellular membrane ion pumps form the current sources, whereas the QUASI-STEADY-STATE single ion concentrations on the respective sides of the membrane generate a NERNST POTENTIAL (V_{Nernst}). The Nernst potential represents the chemical potential resulting from the ion concentration as well as the membrane ion DIFFUSION with respect to the individual ions: permeability. For additional ions, the membrane potential is described by the Goldman equation (introduced by DAVID E. GOLDMAN (1910–1998), ALAN LLOYD HODGKIN (1914–1998), and BERNARD KATZ (1911–2003); also known as the GOLDMAN–HODGKIN–KATZ VOLTAGE EQUATION): $V_{Goldman} = (RT/F) \ln \frac{p_{Na}[Na^+]_{out} + p_{K}[K^+]_{out} + p_{Cl}[Cl^-]_{in}}{p_{Na}[Na^+]_{in} + p_{K}[K^+]_{in} + p_{Cl}[Cl^-]_{out}}$. In this concept, the permeability constant for the ions of interest is represented by p_i^* , where the subscript signifies the ions: sodium (Na^+), POTASSIUM (K^+), and chlorine (Cl^-); square brackets denote the concentration of the respective ion ($[Ion]$); T is the temperature; R is the GAS constant ($R = 8.314 \text{ J/molK}$); and $F = 96485 \text{ C/mol}$ is the FARADAY CONSTANT. The subscripts “in” and “out” denote the ion migration for the CELL. A typical value for the RESTING POTENTIAL is -90 mV . It is negative because cells are more negative relative to the surrounding medium. Cells that are excitable have the ability to rapidly reverse the potential, causing it to be slightly positive. The potential that is generated in this process is known as the ACTION POTENTIAL.

The total sum of the currents can be described using KIRCHHOFF'S LAW (named after GUSTAV ROBERT KIRCHHOFF [1824–1887]): $C_m(d\Delta\Phi_m/dt) + I_{Na} + I_K + I_{Leak} - I_{pump} = 0$, where I_{Leak} represents the current resulting from free moving charges through orifices in the membrane, $\Delta\Phi_m$ is the Nernst potential across the membrane, I_{pump} is the current composed of ions forced into the cellular system, and I_{Na} and I_K respectively indicate the current from gated ion conduction for sodium and potassium. Including the respective ion conductance (g_i) and NERNST POTENTIAL for the ions involving the membrane capacitance is tied to the ion FLOW under steady-state conditions by OHM'S LAW as $C_m(d\Delta\Phi_m/dt) = I_{pump} - (\Delta\Phi_m - \Delta\Phi_{Na})g_{Na} - (\Delta\Phi_m - \Delta\Phi_K)g_K - (\Delta\Phi_m - \Delta\Phi_{Leak})g_{Leak}$. Also considered is the equivalent membrane circuit (see Figure M.72).

Figure M.72 Equivalent circuit for a biological cell, generally also capable of producing an action-potential.

Membrane potential

[biophysics, chemical, energy] Also called RESTING POTENTIAL of a CELL. Cells have the chemical and genetic content enclosed by membranes. The MEMBRANE controls the in and out flows of ions (e.g., nutrients and wastes) by means of voltage-gated gap junctions and ION channels. The trans-membrane potential is the result of ion composition difference between intracellular and extracellular compartments, next to the POLARIZATION of the molecules of the membrane in specific locations such as the ion channels. For every cell, two ionic solutions are separated by a membrane with similar and dissimilar ions on either side. The membrane is apparently permeable to some of the ions. This permeability results in both an electric potential and OSMOTIC PRESSURE across the membrane. This condition is known and the DONNAN EQUILIBRIUM between the two sides of the membrane. The CELL MEMBRANE is assumed to contain a one-for-one sodium/POTASSIUM ($Na^+ \leftrightarrow K^+$) exchange pump. However, the cell membrane is 50 times more permeable to K^+ and chlorine (Cl^-) than to Na^+ . The net efflux of 388 ions requires a net efflux of 69,840 H_2O molecules to maintain osmotic balance. In the intracellular compartment, potassium levels are high in comparison to the extracellular compartment. Sodium levels are high in the extracellular compartment in comparison to the intracellular compartment. In addition to the Na^+/K^+ -pump there will be free DIFFUSION, which is described by Fick's law: $J_s = -D(d[S]/dx)$, with D the diffusion coefficient and $[S]$ the arbitrary ion concentration and dx the DISTANCE over which the diffusion takes place. Additionally, there is a significant concentration of

negatively charged, impermeable proteins in the intracellular compartment that accounts for an appreciable portion of the **NEGATIVE CHARGE** in the intracellular compartment relative to the extracellular compartment. The separation of charges on either side of the cell membrane describes a **CAPACITOR** that has an electric potential associated with the charge distribution. A standard parallel plate capacitor consists of two conducting plates of area separated by distance d . A **POSITIVE CHARGE** (q^+) resides on one plate (i.e., extracellular liquid), while an effective negative charge (q^-) resides on the other (i.e., intracellular liquid). The electric field between the plates is $E = Q/A\epsilon_0 = \sigma_e/\epsilon_0$, where Q represents the total charge present on the plate with surface area A , yielding a surface charge density σ_e and ϵ_0 is the electric permittivity. This charge distribution provides an electric potential: $V = -d(Q/A\epsilon_0) = Q/C_m$, where d is the separation between the two plates and C_m represents the membrane capacitance. The initial description of the membrane potential used the ion distribution. **WALTHER HERMANN NERNST** (1864–1941) developed an equation simply describing membrane potential as being based on differing ion concentrations on the outside (extracellular: e) and inside (intracellular: i) of the membrane, which is described in equilibrium case (i.e., Donnan equilibrium,) as $V_m = V_i - V_e = (RT/nF) \ln([S]_e/[S]_i) = (KT/q) \ln([S]_e/[S]_i) = 26 \text{ mV} \ln([S]_e/[S]_i)$, where $F = 95,484.56 \text{ C/mol}$ is the Faraday's constant, that is, the charge on a **MOLE** of electrons multiplied by n the number of moles in the **SOLUTION**, q is the charge, $[S]_e$ is the extracellular ion concentration of one specific ion (" S "), $[S]_i$ is the intracellular ion concentration, $R = 8.314 \text{ J/mol}\cdot\text{K}$ is the **IDEAL GAS** constant, and K = the Boltzmann constant. This factors in that, in order for an ion to contribute to a membrane potential, the membrane must be permeable to that ion (*also see ACTION POTENTIAL*). The main ions involved in the transmembrane displacement current are **POTASSIUM** (K^+), **sodium** (Na^+), **chlorine** (Cl^-), and **calcium** (Ca^{2+}). In resting cells, the ion current from chlorine and calcium can be neglected. Each ion has a net current associated with the mobility (represented by the conductance) described as $I_S = g_S (V_m - V_S)$, where the subscript m designates the membrane potential and g_S is the ionic conductance for ion S . **DAVID E. GOLDMAN** (1910–1998) worked together with **SIR ALAN LLOYD HODGKIN** (1914–1998) and **SIR BERNARD KATZ** (1911–2003) to expand on the **NERNST EQUATION** including all **PERMEANT** ions describing the membrane potential as $V_m = (58 \text{ mV}) \log_{10} \left(\frac{p_{\text{K}}^* [\text{K}^+]_e + p_{\text{Na}}^* [\text{Na}^+]_e + p_{\text{Cl}}^* [\text{Cl}^-]_i}{p_{\text{K}}^* [\text{K}^+]_i + p_{\text{Na}}^* [\text{Na}^+]_i + p_{\text{Cl}}^* [\text{Cl}^-]_e} \right)$ (often referred to as the Goldman equation), where p_S^* is the **RELATIVE PERMEABILITY** for each specific ion. Some of the ion channels are responsive to external influences such as sound, **GRAVITY**, **OSMOTIC PRESSURE** gradients, and more, and these ion channels operate under a principle referred to as **MECHANOSENSITIVE ACTION** (see [Figure M.73](#)).

Figure M.73 Cell electrical potential mechanism based on chemical gradients.

Mendel, Gregor Johann (1822–1884)

[biomedical, computational, general] Scientist and friar in the then Austrian empire, now Czech Republic. Dr. Mendel realized the concept of chance in combination theory, in particular related to genetic transfer of recessive traits. He described in 1865 how the chance of the expression of the attributes of the recessive gene is related to the occurrence of the square root of the chance of the gene being carried forward (general concept of heredity). He is partially known as the father of modern genetic causality statistics. One of Mendel's professors in Vienna was CHRISTIAN ANDREAS DOPPLER (1803–1853) (see [Figure M.74](#)).

Figure M.74 Gregor Johann Mendel (1822–1884).

Mendeleev, Dmitri Ivanovich [Дми́трий Ива́нович Менделеев] (1834–1907)

[atomic, chemical, mechanics, nuclear, quantum, solid-state] Russian scientist and chemist. Mendeleev's discoveries of a pattern in the structural and energetic configuration of the ELEMENTS led to the composition of the PERIODIC TABLE OF ELEMENTS, based on the NUMERICAL patterns in atomic weights of known substances. He proposed the PERIODIC LAW, describing the electron configuration pattern for the ranking of elements. The QUANTUM THEORY was essential in explaining the perceived regularities. Mendeleev's work was pivotal in revealing the ATOM as the essential building block of the elements whether or not in molecular form. The periodic table is also referred to as Mendeleev's chart. The fact that the chart had several gaps led him to discover three additional elements: GALLIUM (1871), scandium (in 1879), and germanium (1886). Additional

work of Mendeleeev was in THERMODYNAMICS and GAS LAW. He described the concept of critical temperature before the experimental and theoretical verification in the 1860s by Thomas Andrews (1813–1885) (see [Figure M.75](#)).

Figure M.75 Dmitri Ivanovich Mendeleeev (1834–1907).

Meniscus

[biomedical, mechanics] From the Greek word “μηνισκοζ” meaning crescent. Cartilage-based disk with the shape of a “C” positioned between the tibia and the femur acting as a SHOCK ABSORBER and reducer of FRICTION in the knee joint (see [Figure M.76](#)).

Figure M.76 Meniscus of the knee in the human leg.

Meniscus

[fluid dynamics, general] The curvature of a liquid surface in a confined space that holds the LIQUID to the surface by cohesive force, either concave (attractive force from the container, i.e., CAPILLARY [e.g., GLASS], is greater than the cohesive forces within the liquid) or convex (greater COHESION within the liquid) (see Figure M.77).

Figure M.77 (a,b) Liquid surface meniscus on mercury column in narrow flask.

Meniscus lenses

[biomedical, general, optics] Thin LENS used in spectacles (EYE glasses) for corrective VISION (see Figure M.78).

Figure M.78 Meniscus lens concept.

Menten, Maud Leonora (1879–1960)

[biomedical, computational] Canadian scientist, primarily known for her work related to MEDICINE, specifically on chemical reactions and enzyme KINEMATICS (*also see* LEONOR MICHAELIS (1875–1949) and MICHAELIS–MENTEN EQUATION) (see [Figure M.79](#)).

Figure M.79 Maud Leonora Menten (1879–1960). (Courtesy of Smithsonian Institution, Washington, DC.)

Menzel, Donald Howard (1901–1976)

[atomic, chemical, nuclear] Scientist from the United States. His work with RAYMOND THAYER BIRGE (1887–1980) led to the discovery of radio isotopes of hydrogen that occur under normal circumstance in a fraction of the whole with mass number 1 and 2 respectively in a 45,000:1 ratio, established in 1931. Additional contributions to the solid state and chemistry knowledge were in the description of the chemical structure of stars as well as the parameters of the physical structure of the CHROMOSPHERE of the Sun (see [Figure M.80](#)).

Figure M.80 Donald Howard Menzel (1901–1976), photograph by Babette Whipple. (Courtesy of Elizabeth Menzel Davis.)

Mercury barometer

[astrophysics, general, geophysics] Hollow device that has one LEG vacuum sealed, whereas the other leg is exposed to the outside AIR. The shape can be straight cylinder, U-shaped, or tube in a basin exposed to outside air with the top sealed. Through the law of COMMUNICATING VESSELS, the column of mercury rises and lowers when the force on the exposed mercury MENISCUS varies with the external pressure; hence, the height in the VACUUM column is an indication of the force applied by the outside air, with height (h) reaching to the edge of the ATMOSPHERE and density ρ , on the surface area in equivalence to the force applied by the height of the column of mercury. Hence the PRESSURE (P) is sometimes expressed in height (h) of millimeters mercury from $P = \rho gh$. The first MERCURY BAROMETER was introduced by EVANGELISTA TORRICELLI (1608–1647) in 1643. The term mercury barometer is attributed to ROBERT BOYLE (1627–1691) (see [Figure M.81](#)).

Figure M.81 Diagram of open mercury barometer. (Courtesy of Bruce A. Averill and Patricia Eldredge.)

Mercury cell

[general] Solid-state disposable BATTERY with “dry-cell” potential of 1.4V. The advantage of the mercury cell battery is the small size (as used for instance in calculators, HEARING aids, and watches).

Mersenne, “father” Marin (1588–1648)

[acoustics, computational, general] Scientist, theologian, mathematician, and experimentalist from France. Marin Mersenne is often referred to as the father of ACOUSTICS. Father Mersenne was a contemporary of Constantijn Huygens (1596–1687), composer and poet, and the father of the physicist CHRISTIAAN HUYGENS (1629–1695) from the Netherlands, and GALILEO GALILEI (1564–1642), with both he exchanged scientific communications, as well as with numerous other international collaborators of that era. His specific interests were in restructuring the European mathematics efforts and worked with Étienne Pascal (1588–1651), as well as his son BLAISE PASCAL (1623–1662) among other people. Due to his fascination with music, he also became well versed in the acoustics phenomena and described the technical details in 1627, including the dependence of the FREQUENCY (ν) on a string as a function of the square root of the applied tension (F_T) and with respect to the length (ℓ) and mass (m), yielding the resonant frequencies of a string with linear mass density $\mu_\ell = m/\ell$.

(specifically accounting for the diameter of the string), providing base frequency ($n = 1$) and higher harmonics ($n = 1, 2, 3, \dots$): $v_n = n/2\ell\sqrt{(F_T/\mu_\ell)}$. His work also provided an in-depth definition and range of values for the speed of SOUND (see [Figure M.82](#)).

Figure M.82 “Father” Marin Mersenne (1588–1648).

Merton mean speed theorem

[computational, general] Lemma proposed by a group of academics from Oxford, United Kingdom (the so-called Oxford Calculators of Merton College), and French collaborators in the fourteenth century (including the mathematician NICOLE ORESME [c. 1320–1382]), stating that a body that is unvaryingly accelerated will travel an equal DISTANCE as a body with uniform speed, when the accelerated body has a speed that is half its final velocity. The theorem attempts to quantify uniformly accelerated MOTION by matching it to uniform motion.

Meson

[energy, general, nuclear, quantum] Elementary particle component of one quark and one antiquark. A short-lived particle carrying a positive, negative, or zero charge, and having a variable mass in multiples of the mass of the electron. Also called mesotron. They are the complementary particles of BARYON, another subclass of the PARTICLE group HADRON. Mesons, which obey BOSE–EINSTEIN STATISTICS and have zero or integral SPIN ($s = 0, 1, 2, \dots$), are also known as bosons. The known mesons are π , K , ρ , ω , η ; K (heavy), K_A ON, L (light), μ (μ) and π (π), and π ION; and most recently a four-quark hadron: $Z(4430)$ has been introduced, consisting of two quarks and two antiquarks. In contrast, baryons obey FERMI–DIRAC STATISTICS and have half-integral spin; they are also known as fermions. Masses of the known mesons as well as baryons range from one-seventh of that of the PROTON for the π meson, extending 10 times the proton mass. Mesons are subjected to the STRONG NUCLEAR FORCE, in contrast to the LEPTON (see [Figure M.83](#)).

Figure M.83 Graphical representation of the Meson concept.

Meson theory of nuclear forces

[atomic, nuclear] Hypothesis basing the assumption of a nucleon–nucleon potential, a MESON field, which has similarities with electromagnetic fields however with a much greater force and much shorter range. Also known as the Yukawa theory.

Mesosphere

[energy, geophysics] Atmospheric layer between the stratopause and the mesopause, at an altitude between approximately 50 and 80 km. A type of LIGHTNING referred to as sprites can appear in the mesosphere above thunderstorms. In this layer, near the North and South POLES peculiarly, high-altitude noctilucent clouds are sometimes formed (see [Figure M.84](#)).

Figure M.84 Mesosphere of earth's atmosphere.

M

Metabolic activity

[biomedical, chemical, thermodynamics] The full complement of all chemical reactions that supports and maintains the cellular ACTIVITY (i.e., “life”) in an organism. Metabolic activity involves the transformation of MATTER to ENERGY on a cellular level. Both ELEMENTS are required to sustain life. Two types of metabolic processes are available on a chemical level: anabolic and catabolic. The anabolic METABOLISM is constructive, forming large molecules from small molecules in an ENDOTHERMIC PROCESS. The catabolic mechanism is exothermic and breaks down large molecules. Every person has an individualized metabolic rate, depending on hormonal balances and past and present activity, with inherent AGE and gender related implications. Due to this individualized metabolic activity, a purely nutrition-based weight control by means of diets never yields the same outcome for everyone. A baseline metabolic rate can be used linking CALORIC consumption requirements against the weight of the biological entity.

Metabolic flux analysis (MFA)

[biomedical, chemical, computational] Methodology for the determination of the migration of metabolic chemical pathway fluxes. The intracellular fluxes are derived from a model for the major intracellular reactions based on intracellular MASS BALANCE for all respective metabolites. The stoichiometric model defines the metabolic flux-pathway map, representing the CONSERVATION OF MASS on a purely chemical level, that is, atomic constituents. The parameters used in the computational process are the physical quantities of extracellular fluxes, as measured by chemical concentrations, including the derived representative uptake rates of substrates as well as secretion rates of metabolites. The FLUX calculations provide a multiparameter diagram of the biochemical reactions with an approximation of the steady-state rate for each individual reaction in the diagram (i.e., the flux); this yields a metabolic flux map. MFA studies are executed by making cells consume a radioactively labeled substrate (e.g., ^{13}C -labeled GLUCOSE). Subsequently the incorporation of the ISOTOPE is measured to determine the reaction mechanism. The downstream metabolites are derived from mass spectrometry. The computational model of the intracellular metabolic network defines the pathway fluxes

in association with physical measurements of extracellular nutrient consumption and constituent excretion rates of the respective isotope- labeled data. The detection mechanism relies on the production of microbes with imbedded ^{13}C -labeled glucose, followed by gas-CHROMATOGRAPHY mass spectrometric QUANTIFICATION of amino acids with protein-bound ^{13}C -patterns. By systematically accounting for all extracellular ^{13}C in and out fluxes as well as all other major intracellular pathways, the MFA can simulate and recreate the cellular METABOLISM based on comprehensive flux maps. The metabolic flux analysis network describes the conversion of fundamental raw material S_0 into substance S (consider for instance the intake of substrate from outside of the cell). Subsequently, substance S is converted into material A and B through the respective reactions r_1 and r_2 . Furthermore, A is converted to chemical substance C by reaction r_3 , and reaction r_4 converts constituent B into D . In general, the reaction in the map does not contain the specific stoichiometric information. The map is supplied with additional biochemical reactions, for which the stoichiometric relationships have been established and verified. The following examples are an indication of potential sequence of events: glucose + PEP $\rightarrow$ glucose - 6 - P + pyruvate, where PEP represents phosphoenolpyruvic ACID, which can be converted to glucose; respectively: pyruvate + NADH $\rightarrow$ lactate + NAD^+ , or glucose - 6 - P + ATP $\rightarrow$ 2 - glyceraldehyde - 3 - P + ADP, where ATP (ADENOSINE TRIPHOSPHATE) and ADP (ADENOSINE DIPHOSPHATE) are the energized and reduced forms of the renewable intercellular ENERGY source and NADH (nicotinamide adenine dinucleotide) the coenzyme and electron donor. The potential reaction balance proceeds as follows: reaction 0 (raw material conversion): $S_0 \xrightarrow{r_0} S$; respectively $S \xrightarrow{r_1} A$, $S \xrightarrow{r_2} B$, $A \xrightarrow{r_3} C$, and $B \xrightarrow{r_4} D$. In these cases, the material balance turns out to be: $dS_0/dt = -r_0$; $(dS/dt) = r_0 - r_1 - r_2$; $dA/dt = r_1 - r_3$, $dB/dt = r_2 - r_4$; $dC/dt = r_3$; $dD/dt = r_4$, where r_i is the respective reaction rate for each process, which can be represented in matrix format, yielding the stoichiometric matrix $\tilde{G}$, and the reactions are captured by the reaction vector

$$\tilde{v} = \begin{pmatrix} r_0 \\ r_1 \\ r_2 \\ r_3 \\ r_4 \end{pmatrix},$$

providing

$$\begin{pmatrix} S_0 \\ S \\ A \\ B \\ C \\ D \end{pmatrix} = \tilde{G}^T \tilde{v} = \begin{bmatrix} -1 & 0 & 0 & 0 & 0 \\ 1 & -1 & -1 & 0 & 0 \\ 0 & 1 & 0 & -1 & 0 \\ 0 & 0 & 1 & 0 & -1 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \begin{pmatrix} r_0 \\ r_1 \\ r_2 \\ r_3 \\ r_4 \end{pmatrix},$$

where

$$\begin{pmatrix} S_0 \\ S \\ A \\ B \\ C \\ D \end{pmatrix}$$

represents the state vector, containing the state variables (see Figure M.85).

Figure M.85 Metabolic activity schematics. (Courtesy of Intermediary metabolism; Bart P. Braeckman, Koen Houthoofd, Jacques R. Vanfleteren. Wormbook; Intermediary metabolism (February 16, 2009), WormBook, ed. The C. elegans Research Community, WormBook, doi/10.1895/wormbook.1.146.1, http://www.wormbook.org/http://www.wormbook.org/chapters/www_intermetabolism/intermetabolism.pdf.)

Metabolism

[biomedical, chemical, computational] Cellular physiological process of chemical conversion (e.g., consumption; for instance, proteins and carbohydrates) and formation of the renewable ENERGY source ADENOSINE TRIPHOSPHATE (ATP) from ADENOSINE DIPHOSPHATE (ADP) and phosphor under influence of nucleic ACID catalysts and enzymes such as insulin. The process is dependent on the formation of solutes from solids (with a specific rate constant) and relies on DIFFUSION for some of the supply passive mechanisms as well as ACTIVE TRANSPORT through the cellular MEMBRANE. The metabolic pathway also involves the RESPIRATION process for oxygen supply used for OXIDATION and exothermic reactions. The metabolic process can be modeled in a first-order approximation by an EULER METHOD, linking the respective chemical constituent gradient in the chemical PHASE TRANSITION (f) by location (x_n , with neighbor x_{n+1}) as $x_{n+1} = x_n + \Delta x f(x_n, y_n)$, and in second order by the RUNGE-KUTTA approximation $k_1 = x f(x_n, y_n)$, where k_1 is the formation rate of phosphorylation of enzyme R by kinase, with R representing the concentration of enzyme R, x a location parameter;

$k_2 = \mathcal{N}f(x_n + (1/2)x, y_n + (1/2)k_1)$, where k_2 is the loss rate of phosphorylation of enzyme R by a pH change influence, and $x_{n+1} = x_n + k_2 + \mathcal{O}(x^3)$, with $\mathcal{O}$ a chemical reaction function (with an associated reaction response).

Metacenter

[fluid dynamics] The theoretical vertical line passing through the center of BUOYANCY with respect to the vertical line passing through the CENTER OF GRAVITY when a floating body is tipped, hence crating a torque. The center of buoyancy is the effective center of the displaced fluid (e.g., the FLUID displaced by the hull of a ship), the point where the buoyant force is theoretically acting on under steady-state conditions (see Figure M.86).

Figure M.86 Metacenter, in this case outlined for a tipping sail-boat.

Metacentric height (h_m)

[fluid dynamics] Condition for the stability of a solid floating body. A specific example is found for ships, in particular with respect to a solid load. The DISTANCE between the center of mass of the floating body and the METACENTER for the floating body (h_m), where the CENTER OF GRAVITY should exert a torque with respect to the metacenter that forces the floating object to erect itself, meaning prevent it from tipping over. Metacentric height has consequences for the natural period of rolling for the hull of a ship. A large metacentric height will result in shorter periods of roll, which will create uncomfortable sensations generally for passengers. Specifically there is an optimal range associated with the metacentric height for stability and comfort. The period of roll (T_{roll}) is expressed as $T_{\text{roll}} = 2\pi R_g / \sqrt{gb_m}$, where g is the GRAVITATIONAL ACCELERATION, and $R_g = \sqrt{I/A}$ the RADIUS OF GYRATION, also referred to as gyradius, where I is the MOMENT OF INERTIA of the object in the direction of roll, and A is the surface area of the buoyant object under the LIQUID surface. The radius of gyration is a measure of the size of an object, in this case the surface of a floating body, given by the root mean square distance for a representative number of locations on the surface of the objects and associated parts with respect to the center of gravity over the length of the object. This will place a limitation on the validity of the radius of gyration with respect to a minimum longitudinal dimension.

Metal

[general, mechanics, nuclear, quantum] ELEMENT or alloy with a shine, the metallic shine and have a high density. Metals are generally not pliable. Metals are conductive for electric current and are good thermal conductors at room temperature; however, not all metals are magnetic. Certain metals are LIQUID at room temperature, for instance mercury and gallium-based alloys, since GALLIUM is generally not found in free form. The conductivity of metals is the result of one or more loosely bound valence

electrons that can easily be freed. The relative ease of releasing the outer electron results from a low IONIZATION ENERGY and low ELECTRONEGATIVITY for the respective ELEMENTS. Metals are found in the PERIODIC TABLE OF ELEMENTS as groups; group IA and group IIA (the alkali metals, which can be considered the most active metals) and the transition elements, groups IB to VIIIB. Alkali metals have their outermost (VALENCE) electron in an s-electron configuration (the BOHR ATOMIC MODEL) orbit. Metals include, but not limited to, the following elements: aluminum, caesium (cesium), calcium, copper, francium, gallium, germanium, gold, IRON, lead, LITHIUM, mercury, neodymium, platinum, potassium, rubidium, silicon, silver, sodium, TITANIUM, uranium, and additionally alloys such as brass and bronze. Most metal oxides are transparent (most well-known metal oxides: the ceramic [white] aluminum oxide $[Al_2O_3]$, and the transparent silicon oxide $[SiO_2]$), specifically also forming garnet crystals. The metallic structure relies on the metallic bonds holding the atoms together. Metallic bonds are electromagnetic interactions between atoms resulting from delocalized electrons (the conduction electrons), basically allowing the valence electrons to share hosts. The quantum-mechanical aspect of the metallic bound allows the conduction electrons to distribute their density (as a “cloud”) equally over all atoms, where the atoms inherently function as neutral (noncharged) entities. The metallic structure relies on close-packed fitting, with as many atoms as possible into the available atomic volume. Each ATOM in this structure has 12 touching neighbors. For the applicable metals, this is described as “12-co-ordinated.” Certain metals are packed less densely (notably those in group 1 of the periodic table), having only 8 neighboring atoms touching. These configurations are called “8-co-ordinated.” Generally metals are not dramatically efficient in their organization. Any piece of metal is made up of regions of regularity, consisting of grain boundaries at which the atoms have become misaligned from the ideal homogeneous LATTICE structure, forming “crystal grain.” The “crystal grains” allow for the formation of localized current loops, creating localized magnetic fields as described by the BIOT–SAVART LAW. These current loops, and implied associated MAGNETIC FIELD vector, can line up to form a PERMANENT MAGNET.

M

Metal detector

[electronics, general] Detection device responding to the changes in DIELECTRIC properties, which result in a change in the self-inductance of a coil in an *LRC* circuit (INDUCTOR (*L*), RESISTOR (*R*), and CAPACITOR (*C*) electronic resonator), with the inherent change in resonant frequency $\omega_0 = (LC)^{-1/2}$ ($\nu = \omega_0/2\pi$), with the bandwidth defined by the QUALITY FACTOR: $Q = \omega_0 L/R$. The bandwidth provides a means of separation with respect to particular electronic material properties. This mechanism of action is applied to passengers on airport screening, and by treasure hunters looking for coins and jewelry (see [Figure M.87](#)).

Figure M.87 Metal detector, popular tool for treasure hunters.

Metal fatigue

[general, mechanics] Localized gradual structural damage to a structure made from alloys or metals resulting from cyclic or infrequent repetitive loading in addition to thermal stress, either gradients or broad range fluctuations (with associated EXPANSION/contraction patterns in three-dimensional configuration). The FATIGUE results from applied nominal maximum stress below the ultimate TENSILE STRESS of the material, and generally less than the yield stress limit. When a certain stress threshold is exceeded, on a MICROSCOPIC level, certain threshold, cracks will form, weakening the integrity of the structure on a MACROSCOPIC scale. The continued exposure to the forces involving the implementation of MATERIAL FATIGUE will eventually result in breakage. Forces can for instance result from geophysical origins such as wind generating a RESONANCE of earthquakes, or man-made such as traffic, and repetitive use. One specific example is the TACOMA NARROWS BRIDGE disaster (November 7, 1940) resulting from a specific wind FLOW causing the suspension cable to provide a resonance VIBRATION (aeroelastic flutter) that made the bridge collapse after an exposure over a 2-year time frame, ultimately resulting in a severe oscillatory MOTION that lasted only a few hours when exposed to a steady 65 km/h wind from the southwestern direction (perpendicular to the axis of the bridge), generating a mixed WAVE pattern consisting of transversal, longitudinal, and rotational vibration modes (see Figure M.88).

Figure M.88 Broken key that has bent beyond the failure-mode, or bent multiple times, causing thermal restructuring of the internal molecular build-up to loose cohesion.

Metastable state (equilibrium)

[atomic, nuclear, thermodynamics] An excited state of a NUCLEUS or an ATOM with a short lifetime, which returns to the GROUND STATE by the emission of a GAMMA RAY or visible or infra-red electromagnetic emission over a measurable half-life. The excited state of an atom that, in QUANTUM mechanical terms, describes the transition from “forbidden” metastable states, which are less probable than the ALLOWED TRANSITIONS from other vetted EXCITED STATES. Particularly, the lifetime of an excited state that is *longer* than the ordinary excited states and that is universally shorter than the lifetime of the ground state, which is the lowest energy state, and is predominantly stable. Nuclides with identical numbers of protons but different neutrons are referred to as isotopes, in metastable state. The nuclides with measurable (“long-lived”) life-time have isomeric energy states that are identified as separate nuclei, respectively, designated as ISOMERS. On a MACROSCOPIC level, this also applies to the nonpreferential, and hence less stable, physical condition of a system that can be long-lived with respect to the system’s most stable state. The latter has as example isomerization. In isomerization high-energy isomers are perpetuated by the creation of (conceivably large) BARRIERS in the potential energy, preventing degrading to the ground state. Atomic metastable conditions can be identified by for instance the ZEEMAN EFFECT, based on spectroscopic diagnostic principles. Another macroscopic example on LATTICE base for carbon at standard temperature and pressure is diamond as a metastable form. Diamond can degenerate to graphite, providing excess kinetic energy, only after overcoming the POTENTIAL BARRIER associated with the crystalline LATTICE structure, captured by dispensation of activation energy. The computational aspects of metastability can for instance describe the energies and lifetimes of ionic and molecular states, including but not limited to vibronic and rotational–vibronic states. On macroscopic scale, the metastable

state can refer to a condition that may release potential energy as kinetic energy, such as an avalanche for a metastable mass of snow on the edge of a mountain cliff (*also see LASER*) (see [Figure M.89](#)).

Figure M.89 Energy configuration for a metastable state: a metastable state of weaker energy configuration [potentially an atomic bond, or vibrational state, or cohesive attraction on macroscopic scale] (#1), a transitional ‘saddle’ configuration (#2) and a final state of stronger bond (#3).

Meteor

[astrophysics, geophysics, mechanics] Encounters of galactic projectiles with the Earth’s ATMOSPHERE, were the burn up, and create a visible flash. The observed flash is referred to as a meteor. Meteors occur in the thermosphere. Meteors enter the Earth’s ATMOSPHERE at velocities generally ranging from 10 km/s to 75 km/s, keeping in mind that the earth’s angular velocity in an orbit around the Sun is on average 30 km/s. Also known as “shooting star,” a visible streak of light across the field of view. One of the annually reoccurring meteor showers is the Perseid meteor shower in the first part of August, associated with the COMET Swift Tuttle. The Perseid meteor shower received its name from the direction at which it is seen entering the Earth’s ATMOSPHERE, with the constellation Perseus in the background. This particular meteor shower has been dated back to 36 AD in Chinese astronomical records, but the annual recurrence was documented by Adolphe Quetelet (1796–1874) from Belgium in 1835 (see [Figure M.90](#)).

Figure M.90 Meteor entering the Earth’s atmosphere.

Meteorite

[astrophysics, geophysics, mechanics] Solid space debris released by the break-up of comets and ASTEROIDS.

Meteoroid

[astrophysics, geophysics, mechanics] The smallest projectiles within the SOLAR SYSTEM, ranging in size from large fragments released by the breakdown of ASTEROIDS or comets, to dust expressed as extremely small micrometeoroids.

Meteorology

[energy, fluid dynamics, general, geophysics] Field of PHYSICS dealing with physical phenomena in the lower part of EARTH'S ATMOSPHERE directly related to the weather and providing warnings for people in the path of inclement weather. Several devices have been developed in relation to this field such as the ANEMOMETER, BAROMETER, HYGROMETER, RAIN GAUGE, THERMOMETER, and wind vane (see [Figure M.91](#)).

Figure M.91 Aspect of meteorology. Illustrations of the duties and roles in meteorology.

Meter (m)

[general] Dimension of length in the Systèm International (SI) units system. The origins of the meter date back to the early part of the eighteenth century. The meter was defined as the length of a PENDULUM having a half-period of 1 s; later this was superseded under the rule of Napoleon Bonaparte (1769–1821) in 1791 as 10^{-7} time the length of the meridian through Paris from the pole to the equator. However, there is an inherent error in this definition due to the flattening of the EARTH due to its rotation, introducing a deviation of 0.2 mm. In 1889 the meter was defined as the DISTANCE between two marks on a bar of alloy of platinum with 10% iridium, “accurate” within 0.0001%. In 1960 the definition was replaced by the wavelength of the emission from krypton-86 (transition between $2p_{10}$ and $5d_5$, generating a wavelength of 605.7 nm), specifically $1/299,792,458$ (reference speed of light) of the distance traveled in a VACUUM over 1 s interval (placing the accuracy within the definition of measurement of time).

Method of moments

[acoustics, computational, fluid dynamics, mechanics] One of the oldest NUMERICAL (i.e., discrete) computational methods for obtaining point estimators, primarily based on the LAW OF LARGE NUMBERS. The SOLUTION mechanism is based on solving linear partial differential equations that have been reformulated as integral equations. In an arbitrary experiment, there will be an observable, real-valued variable X based on PROBABILITY. The distribution of the variable X can be assigned with n unknown parameters. The set of parameters can be represented by a virtual n -dimensional parameter space, with the vector coordinate $\bar{\chi} = (\chi_1, \chi_2, \chi_3, \dots, \chi_k)$. In order to fully define the vector, the system needs to be measured k -times, which yields a mean $\langle \chi \rangle = 1/k \sum_{i=1}^k \chi_i$ and VARIANCE (σ^2) . The method of moments estimator for the variance provides $\Sigma^2 = \Sigma_2 - \langle \chi \rangle^2 = 1/k \sum_{i=1}^k (\chi_i - \langle \chi \rangle)^2$. This mechanism essentially solves for boundary

conditions, rather than for the analog stretch of continuous space of the media and objects. In the process of formulating the interaction of electric and magnetic fields with MATTER and the environment, the method of moments provides a tool to solve the MAXWELL EQUATIONS. The method of moments can for instance be used to calculate ANTENNA configuration, efficacy, and function, as well as compatibility with the environmental and atmospheric conditions for interaction with ELECTROMAGNETIC RADIATION, specifically the electromagnetic WAVE propagation in a medium other than in free space (i.e., VACUUM). The key component in the solution mechanism is the formulation of Maxwell's equations as a system of hyperbolic partial differential equations. Alternatively, the objects and the media themselves can be approximated as a distribution of discrete dipoles in order to approximate SCATTERING and absorption of electromagnetic radiation by targets of arbitrary geometry. The accuracy will depend on the number of defined interactions (nuclei in the media, and objects) in the system. Also referred to as the method of weighted RESIDUALS.

Metric system

[general] Units scaled in decimal proportions (yotta: 10²⁴ ...→ yocto: 10⁻²⁴) (see SI-UNITS, Le SYSTÈME INTERNATIONAL D'UNITÉS).

VALUE	VALUE: NORMAL	NOUN	PREFIX (SI)	SYMBOL

Metrology

[acoustics, fluid dynamics, general, mechanics, optics] The science of all practical and theoretical aspects of taking and recording measurements.

Michaelis, Leonor (1875–1949)

[biomedical, computational] Physician from the Prussian Empire, Germany, biochemist, and physical chemist. Michaelis worked with MAUD MENTEN (1879–1960) on the mathematical description of enzymatic kinetic interaction and reaction equations (*also see* MICHAELIS–MENTEN EQUATION) (see [Figure M.92](#)).

Figure M.92 Leonor Michaelis (1875–1949). (Courtesy of Humboldt-Universität zu Berlin, Berlin, Germany, Universitätsbibliothek.) Porträtsammlung Berliner Hochschulelehrer; Historische Sammlungen der Universitäts-Bibliothek; Berlin, Germany.

Michaelis–Menten equation

[biomedical, computational] Mathematical description of the transport of substrates (concentration: $[S]$) and drug-related events that have an enzyme (concentration: $[E]_0$) as a catalyst to drive the reaction. Mediated DIFFUSION is faster than regular diffusion described by the DIFFUSION EQUATION. The reaction will have a production rate (v_{reaction}) that changes with time and is dependent on the chemical concentrations of the constituents. An example of this type of reaction is the binding of oxygen to hemoglobin, which for one depends on the partial oxygen pressure next to the acidity (pH) among other factors such as a catalyst. Frequently the SOLUTION is derived by graphical interpretation with for instance the EADIE–HOFSTEE PLOT. The need for this type of computational approach is due to the often ill-defined experimental boundary conditions. The Michaelis–Menten equation is best described as $v_{\text{reaction}} = V_{\text{max}}([S]/(K_M + [S])) = k_{\text{cat}}[E]_0([S]/(K_M + [S]))$, where V_{max} is the maximum reaction velocity, K_M is the Michaelis–Menten constant, indicating the concentration at which the reaction rate for the enzyme is at half the maximum production rate or reaction velocity, and k_{cat} is the rate of conversion for the substrate molecules to the final product, also referred to as the turnover number. In this case, a small Michaelis–Menten constant (K_M) indicates a high binding affinity. Other applications are for instance DNA–DNA hybridization, and antigen to antibody binding (*also see* LANGMUIR EQUATION for equivalence in the description of ADSORPTION of biomolecular constituents, next to nuclear reactions).

Michelson, Albert Abraham (1852–1931)

[acoustics, atomic, biomedical, general, optics] Physicist and scientist from Germany/Poland, born in what was at the time known as the Kingdom of Prussia, later immigrated to the United States. Michelson is primarily known for his contributions in OPTICS. In 1907 Albert Michelson received the Nobel prize in Physics for his work in SPECTROSCOPY and optical instrumentation (see [Figure M.93](#)).

Figure M.93 Albert Abraham Michelson (1852–1931). (Courtesy of Smithsonian Institution.)

Michelson interferometer

[acoustics, atomic, biomedical, general, optics] Path length balanced device that generates INTERFERENCE when the path of the ENERGY traveling to and from the target or probe site is equal to the length of the path traveled by the identical energy signature (frequency, PHASE, designation [PARTICLE, electromagnetic, pressure wave, etc.] and other parameters of identification and material conditions) in a standardized reference path. The path length equivalence is determined by the coherence length of the WAVE package. The Michelson interferometer can be free space or fiber optic. The Michelson interferometer is characterized by four arms, one incoming, one arm that leads to the target (probe site), one reference arm, and the fourth provides the mechanism of detection of interference as a sensor branch. An optical balancing construction where a beam is split into two components that are branching off in perpendicular directions to interact with two media in the respective arms of the INTERFEROMETER, mainly reflective objects returning the two beams back to a 4th arm where they reunite and the wave patterns interact based on the respective phases of the two beams of electromagnetic

radiation as a function of location. When the light is in phase, the interference will be constructive, alternatively when in the opposite phase the waves will cancel each other (destructive interference) (see Figure M.94).

Figure M.94 Michelson interferometer.

Michelson–Morley experiment

[atomic, nuclear] Experimental design to prove/disprove the existence of ether (also known as AETHER), by ALBERT MICHELSON (1852–1931) and EDWARD MORLEY (1838–1923) in 1887. Ether is the historically assumed medium for the propagation of ELECTROMAGNETIC RADIATION, a concept dating back to BC from the philosophies of the Greek scientists. The experimental sign was attempting to determine the relative MOTION of the EARTH with respect to the perceived LUMINIFEROUS ETHER. The design of the experiment used an INTERFEROMETER to determine the path length difference traveled between arms of a split beam of light. In case the path length of two arms (each with length L_{arm}) is equal, the light will be additive (constructive interference). A similarity can be found with swimming a track parallel to the FLOW of a river and perpendicular respectively, returning at the point of origin over equal distances, executed by two equally capable swimmers departing exactly at same time. The difference in path length expressed as the time traveled along the “ether” and perpendicular to the ether was expressed as $\Delta t \cong (L_{\text{arm}}/c)\beta_M^2$, where $\beta_M = v/c$, with v the speed of the object, and $c = 2.99792458 \times 10^8$ m/s the speed of light. The movement of the Earth would account for the lengthening/shorting of the measuring arm, while the reference arm would remain constant, resulting in a shift of INTERFERENCE fringe in the sensing arm. This phenomenon however went unobserved and the ETHER concept was dismissed. The MICHELSON INTERFEROMETER will provide a respective fringe shift for influence of moving ether expressed as $n = \ell v^2 / \lambda c^2$, where ℓ is the respective arm length, and λ the wavelength of the light.

Microarray

[biomedical] A lab-on-a-chip. A two-dimensional array constructed on a solid substrate, made of a GLASS or silicon thin-film CELL. The array assays a large quantity of biological material. The miniaturized microarray detection method is primarily used in DNA analysis, and through high-throughput

screening, multiplexed and PARALLEL PROCESSING of the configuration of the complex molecule can be derived (see [Figure M.95](#)).

Figure M.95 DNA-Microarray.

Microelectronic-mechanical systems (MEMS)

[acoustics, electronics] Electromechanical systems of integrated electronic and mechanical interactions of components (see [Figure M.96](#)).

Figure M.96 MEMS device miniature microphone/speaker set.

Microfluidics

[biomedical] Fluid manipulation in conduits with dimensions of less than 1 mm diameter. Microfluidics is found in biological PERFUSION, inkjet printers, and “lab-on-chip” designs for chemical analysis as well as targeted delivery at a MICROSCOPIC level. The RHEOLOGY of blood in capillaries is an example of microfluidics that changes the FLUID behavior due to the size of the red blood cell, forming a flat velocity profile in the center of the tub.

Microgravity

[biomedical, general] Projectiles in free fall are generally considered to be weightless. Microgravity can be created in a plane flying in a parabolic arc lasting only several seconds (see [Figure M.97](#)).

Figure M.97 The time event for microgravity during specialized flight patterns.

Microphone

[acoustics, electronics] Device designed to convert pressure fluctuations into an electronic SIGNAL from recording purposes or for real-time amplification and transmission over loud speakers or over RADIO or television channels as well as telephone systems (including mobile phone and ham-radio). A microphone can be constructed from piezoelectric material that under mechanical deformation produces an electric signal that changes in frequency and AMPLITUDE in direct correlation (cause-and-effect) with respect to the

external mechanical stimulus. The mechanical stimulus can be changed in density of a GAS, or physical compression due to movement of a mass of solid or LIQUID (see [Figure M.98](#)).

Figure M.98 Microphone, classic design.

Microprocessor

[electronics, general] Integrated circuit used for performing computational algorithms. Semiconductor CHIP containing a central processing unit (CPU) electronic circuit configuration. The first microprocessor was introduced in 1974 by the Intel® Corporation (founded in 1968) with 8-bit capability, leading to the rapid reduction in the size of the computer to a portable device. The microprocessor forms the HEART of every modern day computer and control unit. Microprocessors provide the logic for most digital devices, ranging from fuel injection to nuclear power plant temperature regulation. The microprocessor is designed with a specific clock speed, well in excess of 2.4 GHz at the time of this work, indicating the number of calculations that can be performed per SECOND. Next to the processor speed, a microprocessor is classified by the bandwidth of the SIGNAL; 8-, 16-, 32-, 64-, or 128-bit (not common in personal computers [PCs]). The processor's "bit" parameter refers to the MAGNITUDE of the data types that the processor can handle next to the size of its registry. A 64-bit processor has the capability of

storing 264 computational values, where the data are also temporarily stored in memory addresses. The 64-bit CPU is hence capable of accessing over 10^9 times as much physical memory in comparison to a 32-bit processor (see [Figure M.99](#)).

Figure M.99 Microprocessor.

Microsaccade

[biomedical, electronics, theoretical] μ -saccade, small random movements (plural) of the EYE across the field of view outlined by the azimuthal and the polar ANGLE in a spherical coordinate system. The movement is predominantly involuntary and is supposedly designed (biologically) to avoid retinal SATURATION. Ocular fixation on a single point in the view will eventually bleach out and will become invisible unless the eye moves away from this point. The body is generally more responsive to change than to status quo. This small amount of eye movement is disorganized with no preferential pattern. Other MOTION of the eye with respect to fixation on a view-point is classified as TREMOR and DRIFT. The movement is shorter than a regular SACCADIC. The angular motion in humans and animals ranges from 2 to 120 arcmin. This phenomenon was first documented by Robert Darwin (1766–1848) a medical doctor from Great Britain, the father of the naturalist, genetic researcher, and geologist Charles Darwin (1809–1882). Microsaccades also provide the mechanism for the visual interpretation that a pattern of small markings in a dense distribution is moving when looking at it in a fixed stare (see [Figure M.100](#)).

Figure M.100 (a) Illustration of how the microsaccades, high-frequency twitches, are superimposed on the normal drift motion (saccades) of the eye movement and (b) representative frequency and angular distribution of microsaccades.

Microscope

[general, imaging, optics] Device used to provide a detailed view of an object with greater RESOLUTION than what can be obtained with the naked eye, with no specific lower limit on the magnification. The standard microscope was what we now consider a magnifying GLASS. The MICROSCOPE is generally constructed of one or more optical ELEMENTS, including lenses, mirrors, and prisms. The use of more than one optical ELEMENT constitutes the compound microscope. The standard optical microscope was developed between 1590 and 1608, independently (debatably), by two teams of LENS makers (eye glasses) from the Netherlands: HANS JANSEN (sixteenth century, no exact dates), and ZACHARIAS JANSEN (1580–1640) and HANS LIPPERSHEY (1570–1619). The microscope was the result of experimentation with lenses since the first eye-glasses were introduced between 1282 and 1285 in Florence, Italy by Alessandro di Spina. The concept was the culmination of the publication of the properties of curved glass providing magnifying by ROGER BACON (1214–1294) in 1262. The compound microscope is attributed to ROBERT HOOKE (1635–1703) in Great Britain, created in 1665, while a similar device was concurrently constructed by Jan Swammerdam (1637–1680) in the Netherlands in 1675. The Hooke microscope was actually constructed by a London instrument maker named Christopher Cock (seventeenth century, no exact dates). The Hooke microscope attained a magnification of 30 times. The Swammerdam microscope reached magnification of 150 times. The microscope was improved by the lens-maker ANTONIE VAN LEEUWENHOEK (1632–1723) from the Netherlands, published in 1716. The van Leeuwenhoek microscope used pinholes and lenses made from water droplets. This device was used in the eighteenth century for the equivalent to current medical pathological investigation. Microscopes in the early 1700s were made using crown glass. In 1733, a breakthrough discovery was made by the amateur optician, Chester Moor Hall (1703–1771) from Great Britain, minimizing CHROMATIC ABERRATION through a combination of lenses made with different refractive materials to form a complex lens. This discovery can be attributed to the introduction of a new lead-containing flint glass. The microscope forms an IMAGE of an object placed in the (adjustable) FOCAL PLANE of a set of or single magnifying glass(es). The magnifying glass is a biconvex axial symmetric glass spheroid. Light reflects from the object (specimen) placed under the lenses and is refracted at the air–glass interface and again exiting at the glass–air interface. In case the formed image cannot be projected on a screen, it is defined as a virtual image. Alternatively when the image can be projected on a screen, the image is defined as real. The refracted light is hence focused by the lens providing the formation of an image, either virtual or real. When a virtual image is formed, the EYE can observe this on the RETINA, appearing on the same side of the lens, and in the approximately similar azimuth and ZENITH locations, as where the object is located. The virtual image formed by the lens and observed by the eye is most sharp when its position falls in the NEAR POINT of the eye. The near point of the eye is the closest DISTANCE between an object and the cornea of the lens of the eye that can be perceived as a well-defined image by the retina. The near point for the average human being is approximately 250 mm removed from the cornea. In order to understand the function of the microscope, first some of the basic principles of ray forming by a single lens in image formation need to be described. Two general types of lenses can be distinguished: concave and convex. A concave lens is thinner on the optical axis than farther removed from the axis of symmetry. Concave lenses are also called diverging lenses since they will never produce a real image. Convex lenses are thicker on the optical axis and will produce a real image on the opposite side of the lens when the object is at a distance greater than the focal length. When the object is at a distance shorter than the focal length, the convex lens will also form a virtual image. The distance on the optical axis of the lens with respect to the material center to the plane where the light from an object at infinity forms the smallest real image, generally undistinguishable since all rays from every point on the object converge, is known as the focal distance f . The focal length is positive for the convex lens (also known as POSITIVE LENS) and the focal length for a concave lens is negative (virtual, and this lens is also called a “negative lens”). The image of the object formed by the convex lens appears inverted in the FOCAL POINT. The power of the lens is defined as the inverse of the focal length of the lens. The image formed by any lens is a factor or fraction greater than the object. The object has a height b_o , the image has a height b_i , and the distance of the image to the lens is d_i , while the object distance from the lens is d_o . The lateral magnification for a simple lens is defined as the ratio of the image height over the object height, which can be shown by geometric analysis to be equal to the ratio of the respective distances as $M = b_i / b_o = d_i / d_o$. Modern microscopes have a minimum of two lenses or two lens sets (corrections for chromatic and spherical

aberration), and objective and an ocular. The ocular lens is located in the eyepiece of the microscope. The ocular generally has a magnification of 10 times. The objective lens is placed closest to the specimen on the examination stage. The objective is selected to suit the required total magnification for the investigation of details with the appropriate resolution. The total magnification is the product of the two respective magnifications for the two lens systems. Based on the Raleigh criterion or **ABBE CONDITION**, the maximum magnification for a standard optical microscope operating at the wavelength with peak retinal sensitivity (570 nm) is 600 times. Different types of microscope have been developed to overcome the limitations in **OPTICAL MAGNIFICATION**. Additionally, the standard optical microscope has been outfitted with techniques to take advantage of the electromagnetic parameters, including phase and wavelength, and polarization **ANGLE** to enhance the contrast for optimization in detection of deviations from the norm. One type of microscope takes advantage of the wave properties of light and is called the **INTERFERENCE** microscope, taking advantage of the fact that the optical path length varies with local index of **REFRACTION**. The **PHASE** contrast microscopy also relies on interference of light waves, with deviations resulting from diffraction, with associated phase retardation. Another type of microscope uses the **DISPERSION** of light in tissues based on the direction of the electric field and the direction of the electric influences of the medium under investigation, known as **BIREFRINGENCE** of most tissues. In particular, the loss of the birefringence resulting from clinical (disease) or external damage to the tissue, artificially induced (e.g., coagulation), and is referred to as polarization microscope. Many other **MICROSCOPIC** devices have been developed over time, not all based on the optical principles. Some optical microscope variations are fluorescent microscopy, confocal microscopy, scanning optical microscopy, two-photon microscopy, and near-field-scanning optical microscopy. One of the latest microscope introductions is three-dimensional imaging with optical coherent tomography (**OCT**) imaging devices, based on the phase information of the wave property of light, relying on interference. Microscopes using other techniques are the **ELECTRON MICROSCOPE** based on the **DE BROGLIE WAVELENGTH** of an accelerated charge **PROJECTILE** as does the helium-ion microscope. Additional resources are the **ATOMIC-FORCE MICROSCOPE (AFM)** using the electronic attraction and repulsion of the medium and an extremely fine needle tip mounted on a cantilever (see [Figure M.101](#)).

Figure M.101 Microscope.

[general, nuclear] *See* NUCLEAR MICROSCOPE.

Microscope, resolving power

[atomic, nuclear] *See* RESOLVING POWER.

Microscope, scanning ion-conductance

[general] *See* SCANNING ION-CONDUCTANCE MICROSCOPE.

Microscopic

[biomedical, chemical, general, solid-state] Not visible by the naked eye, requiring visual aids to identify the characteristics; that is, the use of a magnifying GLASS or MICROSCOPE.

Microstate

[general, mechanics, thermodynamics] Thermodynamic condition that applies to a MICROSCOPIC subsegment of a system. This principle applies specifically to statistical MECHANICS. The assembly of all local microstates dictates the collective macrostate of the medium or entire system.

Microtome

[biomedical, mechanics] Precision cutting device used for preparation of histology slides. The tissue in most cases is embedded in paraffin after being fixed first in formaldehyde or equivalent chemical. Additional operational mechanism of action employs a frozen section and the device is called a cryostat microtome (see [Figure M.102](#)).

Figure M.102 Microtome cutting device used for histology slide preparation. An extremely thin slice of tissue imbedded in paraffin is cut from the large formaldehyde fixed block and curls off the blade. The wafer-thin slice of tissue is subsequently placed on a microscope glass-slide for examination of the tissue structure and potential identification of pathological deviation in cell structure (e.g., cancer cells mixed-in with the regular organ cells) under microscopic examination.

Microwave

[general] Electromagnetic WAVE in the wavelength spectrum ranging from order of millimeter to 1 m, or equivalently, with frequencies ranging from 300 to 0.3 GHz. Most well-known is microwave radiation in the 2.54 GHz range (wavelength: $\lambda = 124$ mm), used in wireless communications such as CELL phones and bluetooth, and the heating of food in the MICROWAVE OVEN. Microwave radiation is generally produced by a magnetron electronic device (see [Figure M.103](#)).

Figure M.103 Microwave with magnetron signal generator depicted.

Microwave imaging

[general] Due to the relatively high-penetration potential of microwave radiation through various media as a function of wavelength, the use of microwave ELECTROMAGNETIC RADIATION can be used as a mechanism for functional and anatomical imaging of biological media as well as for commercial imaging, such as radar. On a biological scale, the electromagnetic interaction with DEPOLARIZATION of groups of cells forms a perturbation that can be localized using line-of-sight, specifically when applying multiple rays at a relative ANGLE with each other in a synchronous detection mechanism arranged in circular symmetry. Radar (acronym for radio detection and ranging) relies on the deflection and detection for boundaries under an operating mechanism very similar to ultrasonic biological imaging and ultrasonic radar. The use of frequency modulation provides an added mechanism for enhanced RESOLUTION and spectral information about the physical properties of the object under scrutiny (see [Figure M.104](#)).

Figure M.104 (a) Microwave signal detection used by police officer for the assessment of the velocity of moving automobiles and (b) spinning RADAR antenna on a ship for reconnaissance.

Microwave oven

[general] Device that relies on the use of millimeter ELECTROMAGNETIC RADIATION for vibrational excitation of MOLECULAR MOTION (i.e., DIELECTRIC heating), resulting in localized heating of the object. The local temperature is the average kinetic ENERGY of the molecular vibrations ($T = (3/2k_b)mv^2$, where k_b is the Boltzmann coefficient, m is the average molecular mass, and v is the vibrational, rotational, and translational velocity). The use of primarily 2.54 GHz limits the use to heating of materials that contain water such as meat or just liquids. The frequency of 2.54 GHz still has relatively low absorption in water vibration, which ensures deep penetration and volumetric heating. High attenuation at higher frequency MICROWAVE will result in primarily surface heating. Large industrial ovens operate at 0.915 GHz (see [Figure M.105](#)).

Figure M.105 Microwave oven used to heat-up a cup of tea.

M

Middle ear

[biomedical, general] Anatomical segment in the HEARING mechanism for mammals conveying the longitudinal pressure WAVE incident on the eardrum (tympanic membrane) at the end of the OUTER EAR, to the oval window on the cochlea of the INNER EAR. The middle ear has a mechanism of controlling the LOUDNESS of the sound propagated to the inner ear (primarily to prevent structural damage as well as increase the AMPLITUDE and frequency resolution). The pivoted bone system (OSSICLES) in the middle ear consisting of the malleus (“hammer”), incus (“anvil”), and stapes (“stirrup”) that can be relaxed with respect to its interconnection, hence reducing the MAGNITUDE of translational movement; reducing the AMPLITUDE applied to the oval window. Keeping in mind that the tympanic MEMBRANE is 20 times larger in area than the oval window, this indicates the first mechanism of “amplification” available for hearing. The ossicles can respond to a

displacement of the tympanic membrane in the order of nanometers, setting the lower limit of hearing at (approximately) 0 dB at approximately 3500 Hz for a healthy young human ear. With excessive loudness, the fibrous/muscular connections between the ossicles wear down, reducing the sensitivity, leading to gradual procession of deafness. Additionally age-related degeneration of the ELASTICITY of biological materials hearing will decline in both frequency response and intensity sensitivity (see [Figure M.106](#)).

Figure M.106 (a) Full diagram of auditory subsystem (ear) and (b) outline of the Middle ear for *Homo sapiens* (humans); left to right: eardrum, malleus, incus, stapes. The eardrum forms the separation from the outer-ear, whereas the stapes are connected to the inner ear at the oval window.

Mie, Gustav Adolf Feodor Wilhelm Ludwig (1868–1957)

[optics] Physicist from Germany. Mie is best known for his description of the interaction of light with large particles in 1908. MIE SCATTERING stand in comparison to RAYLEIGH SCATTERING for PARTICLE size equal to or smaller than the wavelength (see Figure M.107).

Figure M.107 Gustav Adolf Feodor Wilhelm Ludwig Mie (1868–1957).

Mie absorption

[astrophysics, biomedical, optics] Numerical method used to calculate the maximum absorption coefficient of a medium constructed primarily of spherical particles in clear (i.e., transparent) suspension. In line with the spherical geometry of the particulate constituents, the model is symmetric that allows for SEPARATION OF VARIABLES in the HELMHOLTZ EQUATION $(\nabla^2 + k^2)\Psi(r, \theta, \phi) = 0$, in spherical coordinates, where ∇ is the Laplace operator, and $k = \omega/c = 2\pi/\lambda_0$ the WAVENUMBER, where $\omega = 2\pi\nu$ is the ANGULAR VELOCITY, ν the frequency, λ_0 the wavelength of a monochromatic electromagnetic source, and c the speed of light) for the interaction of the RADIANT ENERGY FLUENCE RATE (Ψ) with the medium that applies to this condition. Separation of variables ($\Psi(r, \theta, \phi) = R(r)\Theta(\theta)\Phi(\phi)$), with a radial component $R(r)$, a cylindrical component $\Theta(\theta)$, and an azimuthal component $\Phi(\phi)$, results in three ORDINARY DIFFERENTIAL EQUATIONS $(d^2\{rR(r)\}/dr^2 + (k^2 - [n(n+1)]/r^2)rR(r) = 0$, where n is a separation constant with solutions as spherical BESSEL FUNCTIONS or spherical Hankel functions of the first kind or spherical Neumann functions, $(1/\sin\theta)(d/d\theta)(\sin\theta(d\Theta(\theta)/d\theta)) + (n(n+1) - m^2/(\sin\theta)^2)\Theta(\theta) = 0$, where m is another separation constant with a LEGENDRE FUNCTION ($P_n^m(\theta)$) as solution $\Theta(\theta) = P_n^m(\theta)$, and $d^2\Phi(\phi)/d\phi^2 + m^2\Phi(\phi) = 0$ with $\Phi(\phi) = e^{im(\phi)}$. From these solutions, the absorption efficiency for a sphere (Q_{abs}) can be derived, which is a direct representation of the ABSORPTION COEFFICIENT (μ_a): $Q_{\text{abs}} = 2/\xi \sum_{n=1}^{\infty} \{(2n+1)[\Re(a_n + b_n) - (|a_n|^2 + |b_n|^2)]\}$, where a_n and b_n are coefficients that are functions of the size parameters: $\chi = kr_i$ and $\xi = k(r_i + e)$.

Mie scattering

[astrophysics, computational, optics, particle] Theoretical approximation of the attenuation resulting from SCATTERING based on a spherical particle model. Mie scatter stands next to RAYLEIGH SCATTERING for atomic and molecular media, such as the creation of the blue sky by means of atmospheric gasses. Both the directional pattern (profile of scattering ANGLE) and magnitude of attenuation resulting from redirecting the electromagnetic WAVE while interacting with DIELECTRIC units with spherical geometry in transparent suspension

(e.g., tissue model, space dust, atmospheric vapor [i.e., haze/fog/clouds] or dust, and paint). In the case where the dimension of the PARTICLE characteristics of the ELECTROMAGNETIC RADIATION interacts (i.e., WAVICLE) with is of the order of MAGNITUDE of the WAVELENGTH of the RADIATION, the interaction closely approximates GEOMETRICAL OPTICS. A more precise definition involves the SOLUTION of the MAXWELL EQUATIONS applied to the interface with an isotropic, homogeneous, dielectric sphere. The Maxwell equations solved in spherical coordinates yields the SCATTERING CROSS SECTION: σ_M , and a SCATTERING ANISOTROPY FACTOR: g (see [Figure M.108](#)).

Figure M.108 Overcast sky, potentially with dust, providing Mie scattering red glow.

The scattering anisotropy factor is also described by what is generally referred to as a SCATTERING PHASE FUNCTION. The scattering phase function is defined by the PROBABILITY of a PHOTON being scattered in the direction θ , expressed by $P(\theta)$. This yields $g = \int_0^{4\pi} P(\theta) \cos\theta \, d\omega$, where ω represents the SOLID ANGLE of space. This can also be expressed in vector format. In this case photons are approximated as rays. A photon is regarded as coming in from direction $\vec{s}$, and after scattering the photon path is redirected into direction $\vec{s}'$. This provides the following statement for the angular scattering probability distribution: $g = \int_0^{4\pi} P(\vec{s}, \vec{s}') \cdot (\vec{s}, \vec{s}') \, d\omega$. This accounts for events taking place over the full 4π steradian, a.k.a. spherical geometry. This process often assumes spherical symmetry, which accounts for a radially, and often axially, homogeneous medium.

Milky Way

[astrophysics, thermodynamics] GALAXY constructed of stars, planets, and dust and GAS in which the Earth's SOLAR SYSTEM is located. The generally accepted view and calculated description of the Milky Way is a flat dual "cymbal" shaped assembly of over 100 billion stars and in the order of 400 billion planets. A rough estimate of the diameter of the Milky Way is at this moment in the order of 5.22×10^4 lightyears. The "bulge" in the center of the Milky Way has a spheroidal distribution of stars and planets and potentially a "BLACK HOLE" in the center. The currently accepted value of the DISTANCE of the Sun from the galactic center is 2.77×10^3 light-years, or 8.5 kiloparsecs (a parsec is equal to 2.06×10^5 times the average distance between the Sun and the EARTH), located approximately half-way between the center and the edge of the Milky Way galaxy. A resembling shape of a spiral galaxy is shown for the Splinter Galaxy. All planets, gasses, and stars revolve around the center of the Milky Way in a uniform fashion, with relatively a constant rotational velocity in the plane of the disk; the velocity at the location of our SOLAR SYSTEM is

approximately 240 km/s. The disk of the Milky Way is surrounded by a spheroidal collective of stars, described as a halo, which is seemingly devoid of gasses and dust (see [Figure M.109](#)).

Figure M.109 Reconstruction of what the Milky Way may look like observed from within the distant galaxy (so far we have not traveled outside our solar system), let alone outside our Milky Way.

M

Miller indices

[atomic, nuclear] “Vector” style notation system in crystallography to specify directions and planes in crystal lattices (namely Bravais lattices). The Miller index for a plane defines how the plane intersects with any of the main crystallographic axes of the crystal, respectively solid, and also applies to any parallel plane (*also see* LATTICE PLANES) (see [Figure M.110](#)).

Figure M.110 Miller indices for atomic lattice structures.

Millikan, Robert Andrews (1868–1953)

[atomic, general, nuclear] American scientist and experimentalist. Millikan's contributions to the nuclear model are in his "oil-drop" experiment and the verification of the PHOTOELECTRIC EFFECT in both experimental and mathematical concepts (see [Figure M.111](#)).

Figure M.111 Robert Andrews Millikan (1868–1953), in 1917. (Courtesy of University of Chicago Science Series.)

Millikan oil-drop experiment

[atomic, general, nuclear] An atomizer provides a continuous droplet stream of OIL droplets that fall through the central hole of two plates that have an ELECTRIC FIELD (E) applied. An applied continuous beam of X-RAY radiation forms a mechanism for charging the droplets. Charged droplets will be suspended, actually lifted, while the uncharged (neutral) droplet will continue in free fall, reaching the TERMINAL VELOCITY v_g . The balance of the three forces, GRAVITATION, FLOW resistance, and electric field force, will result in a rising velocity of constant magnitude, depending on the electric field velocity (v_E). The experimental design was implemented by Robert Millikan (1868–1953) and coworkers in 1909. The experiment provided the MAGNITUDE of the charge of an electron (q): $q = (k/e)(v_g + v_E)$, where k_S is a proportionality factor derived by GEORGE GABRIEL STOKES (1819–1903) for the flow resistance $F_R = k_S v = 6\pi\eta r v = 18\pi\left\{\eta^3 v_g / 2g(\rho - \rho_a)\right\}$, where η is the VISCOSITY of the resisting medium, r the radius of the body in FLOW (i.e., droplet radius), g the GRAVITATIONAL ACCELERATION, ρ_d the density of the oil, ρ_m the density of the medium, and v the magnitude of PARTICLE velocity (see [Figure M.112](#)).

Figure M.112 Millikan's oil-drop experiment.

Minimum dissipation theorem

[fluid dynamics] Theoretical approach in nonequilibrium THERMODYNAMICS to form a prediction of likely steady state situations as well as other dynamical structures that a physical system, specifically pertaining to ENERGY flow and real flow, might exhibit. Helmholtz formulated the minimum dissipation energy principle as the energy difference of a stationary flow of INCOMPRESSIBLE FLUID with respect to FLOW with arbitrary MOTION while containing the same velocity distribution. In 1869, HERMANN VON HELMHOLTZ (1821–1894) stated his principle of least viscous dissipation of kinetic energy. This principle entails that for a steady flow in a viscous fluid, with the small flow velocities on the boundaries of an incompressible fluid, under steady-state conditions, will evolve in currents with turbulent tendencies. This perturbation of the LIQUID flow will evolve in a distribution within which the dissipation of kinetic energy by FRICTION is minimal. The bases for the minimal dissipation of energy is that these fluid motions will be below the threshold for TURBULENCE due to viscous forces. In 1878, Helmholtz applied similar principles to electric currents in a SOLUTION of electrolytes that exhibits a concentration gradient. This balance of forces shows nonequilibrium coupling between forces resulting from electric effects and based on DIFFUSION resulting from the concentration gradient. The reciprocal relation discovered by Helmholtz was later redefined by the Norwegian scientist, chemist, and mathematician Lars Onsager (1903–1976). The original expression of Hermann von Helmholtz in 1868 was later redefined by Onsager in 1931 in terms of a force (F , a hypothetical thermal “force,” which proved the mechanism-of-action for the conduction of heat) as $F = \int_V \Phi dV \xrightarrow{\delta F=0} \text{minimum}$, where $\Phi = 1/2 \sum_{i,j=1}^n R_{ij} J_i J_j$, and J_i and J_j are SCALAR forms of thermodynamic flows and R_{ij} the flow corresponding to the RESISTANCE for a VOLUME (V) outlined by a surface (S). This indicates the viscous dissipation that can be minimized. For the Stokes flow, this relates to the rate of strain within the fluid e_{ij}^s (TENSOR), while the flow velocity is bound by $\nabla \cdot \vec{v} = 0$, where the velocity can be disbanded in two components as $\vec{v} = \vec{u} + \vec{w}$, providing two respective rates of strain components e_{ij}^u and e_{ij}^w as $\int_V e_{ij}^u e_{ij}^u dV = 2 \int_{\partial V} w_i n_j e_{ij}^u dS - 2 \int_V \vec{w} \cdot \nabla P dV$, where P is the local pressure. The second term is negligible by definition under the assumed flow conditions, while the first term reaches zero as the components $w_i = 0$ on the surface. The Dutch mathematician Diederik Korteweg (1848–1941) in 1883 verified Helmholtz’s hypothesis, stating that in any basically connected region, with known boundary velocities, meaning that the squares and products of the velocities of an incompressible viscous fluid may be neglected when small and uniformly distributed, there will be only one solution to the equations for the steady motion, and this solution is always nondiverging and stable.

Minimum energy

[fluid dynamics] Statement by LORD KELVIN (1824–1907) in 1910 pertaining to the fact that an irrotational motion of a LIQUID occupying a simply connected region contains less kinetic ENERGY than any other (rotational or otherwise turbulent) motion corresponding to a mechanism of MOTION that has equivalent normal velocity conditions on the outlying boundary of the system’s domain (e.g., surface of a volume of FLUID in FLOW). A theorem in FLUID DYNAMICS relates the steady state condition to minimum kinetic energy of an ideal fluid. The ideal fluid will be inviscid, incompressible, and irrotational. The SOLUTION provides statements concerning the POTENTIAL FLOW uniqueness. Also known as Kelvin’s minimum energy theorem (*also see* MINIMUM DISSIPATION THEOREM FOR COMPARISON).

Minimum mean square error

[acoustics, computational] In the process of making systematic estimates on behalf of predictions with respect to quantities or making predictions, the use of data obtained from similar systems can be useful but error prone. Certain assumptions or established connects must be made between the unknown and the known systems of values. Choosing the estimate wisely will rely on establishing a minimum mean square error. Combining multiple values that are somehow correlated to another ultimate parameter relies on a process referred to as linear minimum mean square error estimation, applying recursive values to provide the additive error. The estimate can be based on a PROBABILITY distribution ($f_Y(y)$), which is either known or inferred, providing the estimate ($\hat{y}$) for a random variable (Y). For this the minimization process follows, minimize: $\text{ERROR}[(Y - \hat{y})^2] = \int (y - \hat{y})^2 f_Y(y) dy$, which yields the variance σ_Y^2 .

Minimum phase filter

[acoustics, computational, theoretical] Electronic or mechanical (ACOUSTICS) filter based on the fact that the linearity of response to the PHASE of a WAVE is not critical in preserving the waveshape. In this case, we may allow the phase to be arbitrary, or alternatively to define the phase in such a way that the AMPLITUDE response to the process (and inherently the processing algorithm) is easier to match. In SIGNAL PROCESSING, the minimum phase filters are by definition stable due to the fact that the POLES must be inside the unit circle of the defined region of validity. In addition, the inverse filter is also stable when the operator is minimum phase since the function zeros must also be inside the unit circle. Mathematically, minimum phase filters form an algebraic operator group in which the ELEMENTS are formed by respective IMPULSE RESPONSE contributions and the group operation is formed by convolution.

Minimum velocity of water waves

[fluid dynamics] Wavelength- dependent formulation defining the validity of applying the WAVE EQUATION to a problem in the transition from CAPILLARY WAVES to GRAVITATIONAL WAVES. This velocity limit places a threshold on the application of the wave model to be used. Under capillary WAVE MOTION, the SURFACE TENSION has an over powering force influence on the wave description. Generally, water waves with a wavelength less than $\lambda = 0.0173$ m can be considered capillary waves. At this point, the PHASE VELOCITY has a minimum value 0.231 m/s. Note that the velocity of water waves (v) beyond this point is a function of depth (h), as $v = \sqrt{((g\lambda/2\pi) \tanh[2\pi(h/\lambda)])}$, which goes asymptotically to $v = \sqrt{(g\lambda/2\pi)}$ for deep water (see Figure M.113).

Figure M.113 The velocity of waves on water (liquid in general) is a function of the depth h to $h + \eta$ with respect to wavelength (i.e., prone to dispersion) while the water surface moves down the “slice” of water to the bottom of the ocean or river will change in “thickness” dx to $dx + d\chi$ with respect to the raised water surface, providing for the slice of width L in continuity: $Lhdx = L(h + \eta)(dx + d\chi)$, which yields $\eta = -h(\partial\chi/\partial x)$, converted into the wave-equation: $\partial^2\chi/\partial t^2 = gh(\partial^2\chi/\partial x^2)$, which provides the wave velocity $v = \sqrt{gh}$, g the gravitational acceleration.

Mini-sparker

[acoustics, computational, geophysics] Agitation source in a geophysical seismic model, primarily based on mechanical pulse response. The concept also applies to computational modeling of the response of hydrophones in deriving the WAVE diffraction response function and in calibration. The mini-sparker will have a frequency response (i.e., spectral profile) and pulse shape. On a smaller scale, the process applies to sonic imaging in marine applications, such as submarine echo ranging.

Mirror

[general, mechanics, optics] Device that forms an IMAGE of an object by means of REFLECTION. Optical and acoustical mirrors can be concave with a FOCAL POINT on the side of the source, or convex, where the focal point is on the opposite side of the device surface with respect to the source. Generally concave will form either a virtual (when the object is placed at a DISTANCE closer than the focal point) or a real image, whereas convex mirrors and flat mirrors always form a virtual image. The focal point (f) of a curved mirror is half the radius of curvature (R): $f = R/2$. The image magnification (M) is the ratio of the image size (i) to the object size (o): $M = i/o$. Parabolic mirrors provide a mechanism to generate a parallel beam from a source with finite dimensions placed in the focal point. The headlights of an automobile are most known for their parabolic mirror shape. Alternatively, the collection of waves from a not perfectly parallel on-axis source to form an image in the focal point of a parabolic mirror will be more likely to form a small spot size than a spherical mirror, providing corrections to SPHERICAL ABERRATIONS. Radio antennas provide the best example of parabolic collection devices, specifically requiring a less than perfect on-axis alignment. Only an infinitely small source will produce a parallel outgoing beam when placed in the focal point of a spherical mirror. Mirrors are used to direct the path of SOUND waves, RADIO and television waves and optical rays. The exercise of outlining the formation of an image resulting from a source configuration and a mirror design is referred to as ray tracing, and can be performed with pen and paper or by computer simulations. In a complex system, both lenses and mirrors can be applied. An aspherical mirror is not symmetric as compared to a standard parabolic mirror. One specific example of an aspherical mirror is found on the passenger side of the car (objects are closer than they appear).

Mirror formula

[general] Formula describing how the size of the object (o) and the IMAGE size (i) are linked by the radius of curvature of the reflecting object (R_{reflect}) used to generate the image: $1/o + 1/i = 2/R_{\text{reflect}}$, note that a converging MIRROR (concave) has positive radius, and a convex mirror has negative radius, where a positive image reflects a real image and a negative image means virtual.

Mirror nuclei

[atomic, nuclear] Atomic nucleus that is constructed of a respective number of neutrons and protons that, in comparison with another nucleus, are mutually interchanged; the number of protons may match the number of neutrons of the mirror and vice versa. The mirror nuclei are generally isotopes, such as ^{14}O and ^{14}C , and may be short-lived. Mirror nuclei will have a mass difference that is the result from the difference in ENERGY (E) configuration between the two nuclei, expressed by the respective energy states (s_i , with respect to GROUND STATE s_0), and specifically the difference in the total population assembly (n , representing the GREEN'S FUNCTION of occupation for the new with respect to the old nucleus for an ISOTOPE; the energy content of the changed state of the isotope [the "MIRROR"] is compared to the indigenous state of the original stable nucleus) of energy states: $\Delta E = a^2 \sum_{s_j s_i} \Gamma_{s_j s_i}^{s_0 s_0} (n'_{s_i} - n_{s_i})$, where $\Gamma_{s_j s_i}^{s_0 s_0}$ represents the Coulomb interaction on an elementary PARTICLE level for the constituents of the NUCLEUS.

Mitochondria

[biomedical, energy] Specialized cellular component (organelles) in living cells that use oxygen. The living CELL (eukaryotic) has a nucleus. The mitochondria have the sole responsibility for the production and storage of ENERGY to make the cell operate, specifically the formation of ADENOSINE TRIPHOSPHATE (ATP) synthesis. In the process executed by the mitochondria, OXIDATION of simple organic compounds produces electrons generated during a chain of four membrane-bound enzymes, housed in the MEMBRANE. The reduction process is referred to as the electron transport or respiratory chain. The final stage involves the reduction of oxygen to produce water, generating an electron movement that builds a proton gradient across the membrane. The PROTON gradient drives the ATP generation as a TURBINE. The mitochondria additionally house several metabolic enzymes that support the survival of the cell. The inner structure of

the mitochondrial membrane uses surface enlargement for optimal performance, since all energy processes take place in the membrane itself, next to the storage in the LIQUID of the organelle. The outer membrane consists of a lipid bilayer that is freely permeable to a broad range of molecules. The permeability to the molecules, specifically smaller than about 5000 daltons, results from the abundance of a channel-forming protein called porin. Some of the enzymes in the mitochondrial FLUID also assist in the production of phosphates that can be converted to ATP, by phosphorylating other nucleotides. Mitochondria have a diameter ranging from 0.5 to 1.0 μm and length ranging from 1 to 10 μm , depending on the type of cell in the biological system (see Figure M.114).

Figure M.114 Microscopic view of a mitochondria in a biological cell.

Mixing

[biomedical, chemical, thermodynamics] Combining fluids and solids. When solids, liquids, and gases are mixed their respective thermodynamic properties as well as that of the combined system will be altered. Mixing a SOLVENT with one of more solutes, or blending constituents in different phases, to form a single PHASE is mixing. Dissolved oxygen in BLOOD forms a mixture as does coffee with milk and sugar. Atmospheric AIR is a mixture of nitrogen, oxygen, argon, and TRACE elements as well as water VAPOR, all acting as ideal gases. The Gibbs ENERGY of a mixture forms the sum of the fractional components, expressed by means of the number of moles (n) and the respective partial molar Gibbs energy ($G^* = \mu_{\text{chem}}$; which is equal to the chemical potential): $G = \sum n_i G_i^*$. Based on the fractional contribution (n_i/n) the change in Gibbs free energy due to mixing is $\Delta G|_{\text{mix}} = nRT \sum_i (n_i/n) \ln(n_i/n)$, with GAS constant: $R = 8.3144621(75) \text{ J/Kmol}$ and the process at temperature T . In case the mixture is for gases at pressure P_i , the Gibbs energy for the mixture can be written as $\Delta G|_{\text{mix}} = \sum_i n_i (\mu_{\text{chem},i} + RT \ln P_i)$. Similarly, the entropy change as a result of mixing is $\Delta S|_{\text{mix}} = nR \sum_i (n_i/n) \ln(n_i/n)$. The enthalpy change is provided by $\Delta H|_{\text{mix}} = \Delta G|_{\text{mix}} + T \Delta S|_{\text{mix}}$. In all cases, the entropy of the mixture will be greater than that of the components separately. The first-order derivative of the Gibbs free energy provides a negative, implicating that mixing is generally spontaneous. The second-order derivative of the entropy will also always be negative, indicating that the mixture will be adverse to phase separation and supports miscibility (i.e., no preferential mixing ratio) (also see **RAOULT'S LAW**, **HENRY'S LAW**, **FUGACITY**, and **GIBBS–DALTON MIXTURE**).

Mixing length (ℓ_m)

[fluid dynamics] In FLUID flow the mixing length describes the DISTANCE (ℓ_m) over which the momentum transfer takes place within a NEWTONIAN FLUID thin shear BOUNDARY LAYER by means of TURBULENCE Reynolds stresses under the influence of Boussineq eddy viscosity (mathematician from France, Joseph Valentin Boussineq [1842–1929]), and is proportional to the half-width of the shear layer (ℓ_s) for free SHEAR FLOW. The ratio of shear layer to mixing length for specific objects is, for instance, $\ell_m = 0.09\ell_s$ for plane JET flow, and $\ell_m = 0.075\ell_s$ for circular jet flow. The concept was introduced by LUDWIG PRANDTL (1875–1953) in. The eddy VISCOSITY MODEL is described as $-u'_i u'_j = \eta_T ((\partial U_i / \partial x_j) + (\partial U_j / \partial x_i)) - 2/3 \delta_{ij} \epsilon_{\text{Boussineq}}$

where $u'_i u'_j$ is the average of the product of the horizontal and vertical components, known as REYNOLDS STRESS, $\eta_T = \ell_m'^2 |\partial U_k / \partial x_k|$ is the eddy viscosity, measured in the direction of FLOW, u'_n the FLOW velocity components in the respective dimensional reference frame with components ($n = (i, j, k)$), U_n is the, δ_{ij} the Kronecker delta function, and $\kappa_{\text{Boussinesq}} = |u'_m u'_m|/2$. Ludwig Prandtl (1875–1953) proposed that the mixing length is linked to the eddy viscosity and the turbulent velocity as $\eta_T \sim u \ell_m$; furthermore, Prandtl postulated a link between the flow velocity component and the turbulent velocity component as $u \sim \ell_m |\partial U_j / \partial x_j|$. (Note: For incompressible flow of a homogeneous fluid the flow velocities can be split into a mean part $[u_i]$ and a fluctuating part $[u'_i]$ using Reynolds decomposition, defined as $u_i = u_i + u'_i$.)

Mixing time ($\theta_m = t_m/t_c$)

[chemical, computational, mechanical, thermodynamics] Dimensionless number yielding the ration between the time to phenomenological time frame: t_m , and the time to pass through one CIRCULATION loop, cycling time: t_c . In computational PHYSICS this refers to the relative time that RANDOM WALK phenomena will intersect. In MECHANICS it relates to the time frame needed to achieve a set level of homogeneity during physical joining of two or more constituents. In THERMODYNAMICS the mixing time describes the time span in which a phenomenon will evolve into an irreversible process and the ENERGY transitions involved in the time lapse. In computational physics the MARKOV PROCESS will reach a predefined form of homogeneity in PROBABILITY of the distribution of states at the end of the mixing time, also called MARKOV CHAIN MIXING TIME.

MKSA system

[general] System of units based on the elementary parameters: length, meter (m); mass, kilogram (kg); time, second (s); and current (charge flow), AMPERE (A). This makes the Coulomb unit (C), for charge $C = As$. The unit volt (V) for electric potential becomes $V = kg/m^2 s^2 C = kg/m^2 s^3 A$.

Möbius, August Ferdinand (1790–1868)

[astrophysics/astronomy, computational, mechanics] Mathematician and astronomer from Germany, the Prussian Empire. Möbius is best known for his contributions to analytic geometry and his work in topology. Möbius designed the belt that has only “one surface,” the MÖBIUS BAND, or Möbius strip (see [Figure M.115](#)).

Figure M.115 August Ferdinand Möbius (1790–1868).

Möbius band

[computational] Strip of material that has a twist in it so that one can follow the surface around 720° and return to the same point, while a 360° passage will not cross with any points that were passed on the track. This is referred to as an infinite band, or strip, described by AUGUST FERDINAND MÖBIUS (1790–1868) (see [Figure M.116](#)).

Figure M.116 Illustration of the Möbius band concept.

Mode conversion

[acoustics] Sound traveling in a solid material can convert its ENERGY into a different format. One example is a longitudinal (e.g., acoustic) compression wave (P-WAVE, i.e., pressure wave) incident on an interface at an ANGLE. Due to the MICROSCOPIC interaction the longitudinal displacement can cause PARTICLE movement in the transverse direction, which initiates a shear wave (S-wave), or transverse wave (*also see* LAMB WAVE, EVANESCENT WAVE, or RALEIGH WAVE). Nonperpendicular wave incidence on an interface between two media with different acoustic impedances will also generate mode conversion. S-waves and P-waves can be transformed into each other at discontinuities, such as rock-faces in soft crust during an EARTHQUAKE. S-waves can be transmitted in polarized form. Acoustic S-waves were described in the 1800s based on the stress–strain relationship for an isotropic solid, providing the stress relation: $\tau_{ij} = \lambda_L \delta_{ij} \epsilon_{ii} + 2\mu_L \epsilon_{ij}$, where μ_L and λ_L are the Lamé coefficients, introduced by GABRIEL LAMÉ (1795–1870), $\epsilon_{ij} = (1/2)(\partial_j v_i + \partial_i v_j)$ and respectively $\epsilon_{ii} = \partial v_i / \partial x_i$ strain, v_i the velocity in the direction i , ∂_i the gradient change normal to the MOTION, and δ_{ij} the Kronecker delta function. This transforms into the SEISMIC WAVE equation: $\rho(\partial^2 \vec{v} / \partial t^2) = (\lambda_L + 2\mu_L) \nabla(\nabla \cdot \vec{v}) - \mu_L \nabla \times (\nabla \times \vec{v})$, where ρ represents the density of the medium.

Mode-locked laser

[energy, optics, quantum] Laser operating under pulsed conditions that use either an active ELEMENT (an optical modulator: e.g., crystal such as KTP) or a nonlinear passive element (a absorber that can saturate, holding the excitation process and subsequent release followed by a very high ENERGY burst of photons at the wavelength of the medium) in the laser cavity, and are capable of producing extremely short pulses, in the order of femto- and picosecond duration. The spectral width of mode-locked lasers is broad due to the condition linking frequency bandwidth ($\Delta\nu$) to time of light pulse (Δt) as $\Delta\nu\Delta t \geq 1/4\pi$. Active mode-locking can be achieved by integration of either an electro-optic or an acousto-optic modulator in the laser cavity. Examples of active modulators are a Mach–Zehnder integrated optic modulator, or a semiconductor electro-absorption modulator. If the modulation frequency is synchronized with the resonator path of the laser cavity the laser will produce light only at the resonant convergence maxima. Technically, the operational mode of the modulator needs to lock-in with the preferred laser mode (see Figure M.117).

Figure M.117 Graphical representation of the Mode-Locked LASER concept.

Moderator

[nuclear] Rod in a nuclear power reactor that moderates the rate of degradation of URANIUM (^{235}U), by means of slowing down the released fast neutrons, created during the disintegration that can initiate the expedited fission DECAY of the unstable uranium to ^{236}U , under $^{235}\text{U} + n_{\text{slow}} \rightarrow ^{236}\text{U} \rightarrow X + Y + \nu n_{\text{fast}}$, where the reaction is sustained when the constant $\nu_{\text{neutron}} > 1$, the MULTIPLICATION FACTOR, and X and Y are short-lived reaction products. The reaction is regulated by absorbing neutron in carbon rods, known as control rods, regulating the quantity ν_{neutron} . Keeping in mind that naturally occurring uranium (as used in the fuel

rods) only consists of 0.72% ^{235}U , with the balance ^{238}U ; which converts to ^{239}U under absorption of a NEUTRON, thus depleting the FISSION process, however the reaction CROSS SECTION is less than 1 barn $\cong 10^{-28} \text{ m}^2$, while the cross section for ^{235}U is 582 barn. Generally for uranium the process is well controlled for $v_{\text{neutron}} = 2.47$, while for PLUTONIUM (^{239}Pu) $v = 2.91$ (see Figure M.118).

Figure M.118 Boron moderator rods in uranium nuclear power reactor.

Modes of vibration

[general, mechanics] The geometrical deformation patterns in a vibrating MEMBRANE or disk, such as percussion instruments (drums and timpani), as well as in the working of the eardrum. The WAVE EQUATION in two dimension will provide the superposition of multiple waves with different or equal wavelengths traveling or standing in various directions within the vibrating surface: $\partial^2 u / \partial t^2 = v^2 \left((\partial^2 u / \partial x^2) + (\partial^2 u / \partial y^2) \right) = v^2 \left((\partial^2 u / \partial r^2) + (1/r) (\partial u / \partial r) + (1/r^2) (\partial^2 u / \partial \theta^2) \right)$, where u signifies a field MAGNITUDE or a displacement in a Cartesian coordinate system or in a cylindrical coordinate system, and v is the velocity of propagation of the transverse or LONGITUDINAL WAVE in the medium, since the wave may also be confined to a thin layer of gaseous medium. The classification of the EIGENFUNCTION solutions for each geometry provides an indication of the wave form on the surface. The number of modes are a function of the SURFACE TENSION, the diameter (characteristic lengths; the larger the characteristic length the greater the number of modes), elastic modulus, and thickness. These all provide the boundary conditions to the acoustic problem. The AMPLITUDE for higher modes for a small diameter drum will be proportionally less and become negligible (i.e., higher modes become critically damped) (see Figure M.119).

Figure M.119 (a) Outline of some of the simpler modes of vibration for a circular plate. (b) Various, selected (not all) vibrational modes for a circular skin under tension (i.e., drum surface) or metal (steel drum).

Modulus decay

[energy, fluid dynamics, quantum] Generic cosmic SCALAR fields in the GRAND UNIFIED THEORY have consequences which can be analyzed in the form of moduli which will primarily DECAY through gravitationally suppressed interactions only. This generates a production mechanism of gravitinos (the hypothetical GRAVITATION particles) resulting from moduli decay.

Modulus of elasticity (Y)

[general, mechanics] The ratio of the stress to the strain. Description of the elastic properties of linear objects such as cables, shafts, or structural columns subjected to stretch or compression. ELASTICITY is a material property that will result in the restoration to the original shape of the object after distortion (*see* HOOKE'S LAW). Also referred to as the “Young's modulus” of the material.

Modulus of rigidity

[mechanics] Coefficient of ELASTICITY with respect to an applied shearing force, used in materials science $G_{\text{rig}} \equiv \tau_{xy}/\gamma_{xy} = (F/A)/(\Delta x/l) = Fl/A\Delta x$. Defined as the ratio of SHEAR STRESS (the force $[F]$ per unit area (A) : τ_{xy}) to the displacement (Δx) per unit length (l) of the object (i.e., the shear strain: γ_{xy}), derived from the slope of a stress–strain curve. It is also known as shear modulus.

Moens, Adriaan Isebree (1846–1891)

[fluid dynamics] Scientist and physician from the Netherlands. When focusing his research on the principles of arteriosclerosis and vascular stiffness his work produced the foundations for the mathematical description of pulse propagation in flexible tubes in 1878. His collaborator was the mathematician from the Netherlands, Diederik Korteweg (1848–1941). Moens was a close friend of WILLEM EINTHOVEN (1860–1927), the scientist from the Netherlands who introduced the acquisition of the electrocardiogram (*see* Figure M.120).

Figure M.120 Adriaan Isebree Moens (1846–1891). (Courtesy of Museum Boerhaave.)

Moens–Korteweg equation

[fluid dynamics] *See* MOENS–KORTEWEG VELOCITY.

Moens–Korteweg velocity

[computational, fluid dynamics] Mathematical description of a FLOW process in a flexible tube, such as a BLOOD vessel or rubber tube (e.g., oil filling, gasoline pumping, etc.), allowing for local expansion in the cross-sectional flow area. The principle was introduced by the Dutch team ADRIAAN ISEBREE MOENS (1846–1891) and Diederik Korteweg (1848–1941). The elastic WALL expansion process produces a WAVE propagation that travels with a propagation velocity: $v_{\text{MK}} = \sqrt{(E_Y \tau_{\text{wall}}/2R\rho)}$, where E_Y represents the elastic modulus of the tube, τ_{wall}

the local wall thickness, R the radius of the tube, and ρ the LIQUID medium density; under the assumption that EXPANSION is isotropic and responds in isovolumetric change with respect to pulse pressure. It is also known as the MOENS–KORTEWEG EQUATION. This approach is an extension to the NAVIER–STOKES EQUATION.

Moiré pattern

[acoustics, fluid dynamics, optics] The term Moiré has its origin in a woven fabric pattern that creates an impression of three-dimensional depth and speaks to the imagination. The original silk textile weave resembles water waves, dating back to a process found in the fourteenth or fifteenth century called “marmoreus,” later (mid-sixteenth century) interpreted as “mohair.” In the mid-seventeenth century his was interpreted in French as “mouaire.” In the early nineteenth century the term made it back to English as “moire.” Form of ALIASING, where two identical patterns are overlaid at a slight ANGLE to each other whereby false patterns can be observed in an IMAGE. The patterns can be produced by optical aberrations, defects in instrumentation, inferior quality of optical ELEMENTS (lenses, windows), or intentionally resulting from illumination of an uneven surface through a grid pattern where the LIGHT SOURCE is placed at an angle from the observer. The latter will create irregularities in the cross pattern based on the elevation of the uneven surface observed behind the multislit screen. A picket fence can provide the conditions to observe the topography of a flowerbed and grass field while the Sun illuminates through the fence at great ZENITH ANGLE (with respect to the normal). For SOUND, the overlap of two waves can result in a “beat” that is the consequence of the differences between two patterns. In moving patterns, the beat of light and dark also has a beat that is associated with the velocity at which the two patterns move with respect to each other. An optical Moiré pattern can also result from the limitations in RESOLUTION of the recording device with respect to the spatial frequency of a pattern under observation, which can be the EYE looking at a fine line pattern (see Figure M.121).

Figure M.121 Moiré pattern. The fringe interference pattern spatial density can be used to identify elevation when a line pattern is projected on an uneven surface and viewed through a screen with the same spatial frequency as the pattern emerging from the projector, without the requirement of stereoscopic vision.

Moist air

[thermodynamics] Quantification of the amount of water vapor in the AIR (see RELATIVE HUMIDITY, ABSOLUTE HUMIDITY, and SPECIFIC HUMIDITY).

Molar heat capacity (c_m)

[atomic, thermodynamics] Quantity of HEAT (Q) required to produce a temperature (T) rise in a quantity of substance, measured in moles (n) of chemical constituents: $c_m = (1/n)(dQ/dT)$, expressed in J/mol°C, which is, for instance, $c_m^{\text{H}_2\text{O}} = 75.3$ J/mol°C and $c_m^{\text{Gold}} = 25.4$ J/mol°C. This is very similar to the SPECIFIC HEAT of a medium, quantified by mass, which has the following values, at constant pressure $c_p^{\text{H}_2\text{O}} = 4180$ J/kg°C and $c_p^{\text{Gold}} = 130$ J/kg°C.

Molar mass

[thermodynamics] Mass associated with a MOLE of atoms, ions, or molecules quantified by the number of components expressed by AVOGADRO'S NUMBER.

Molding stresses

[acoustics] Residual stress resulting from shape formation in a mold. Residual, or molding stress, is a process-induced stress, encapsulated in a molded part. The stress can result from either FLOW during injection molding or thermal effects (cooling [thermal gradients] or curing related). When the molding stress is greater than the internal COHESION forces the part will warp upon ejection from the mold.

Mole

[atomic, biomedical, chemical, general, thermodynamics] Unit to express the number of atoms, electrons as well as ions and specifically molecules in a volume of medium, either dissolved or as dry mass. The carbon ATOM was initially used to quantify the number of atoms in a mass yielding that 12 g of carbon consists exactly of one mole of carbon [^{12}C] atoms. The number of specific items in 1 mole is defined by the AVOGADRO NUMBER ($N_A = 6.02214078 \times 10^{23} \pm 1.8 \times 10^{16}$ [atoms/gram] or [molecules/gram] [2011 definition]), representing $6.02214078 \times 10^{23} \pm 1.8 \times 10^{16}$ atoms of carbon-12 in 12 g of carbon substance. The definition of molecular mass and quantity of substance dates back to 1805, when JOHN DALTON (1766–1844) published the first table of atomic weights.

Molecular band

[atomic, chemical, nuclear, optics, thermodynamics] Absorption lines observed when a pure substance of molecular emulsion is illuminated by broadband ELECTROMAGNETIC RADIATION. Similarly, during excitation (heating or electric current as well as other means of ENERGY delivery), the spectral emission lines comprise a pure substance of single molecular composition. The “empty” orbital electron bands are separated from the “occupied” electron orbital bands in atomic and molecular structure by the FERMI ENERGY (see Figure M.122).

Figure M.122 Molecular absorption spectrum for the chemical compound Paraben.

Molecular beam

[atomic, nuclear] Stream of molecules ejected within a small **SOLID ANGLE**, moving in the same general direction. The emission of molecules can be through an evacuated chamber or from a pressure **NOZZLE**. Due to the essentially one-directional **MOTION** of the atoms, ions, or molecules, specific properties can be studied under deflection by electric and/or **MAGNETIC** fields. The molecular beam may be directed onto a target, consisting of **GAS**, a solid, or intercept an alternative beam of atoms, ions, or molecules. Molecular beams are inherently of low density to avoid collisions.

Molecular beam epitaxy

[computational, fluid dynamics, mechanics, solid-state, thermodynamics] A specific process used in the formation of crystal structure invented at the Bell Laboratories in the late 1960s and is used in the formation of transistors and other electronic components. The **EPITAXIAL GROWTH** process requires high or ultrahigh **VACUUM** conditions and slow deposit rate, significantly less than 1 nm/s, forming a single crystalline layer on a formed or existing crystalline substrate.

Molecular diameters (σ_{molec})

[nuclear] Based on the van der Waals equation, the “covolume” component, $b = 4N_aV$, with N_a **AVOGADRO'S NUMBER** and V the volume of the **MOLECULE**, can be used to derive the size of the molecule in a **GAS**, when taking the volume of one molecule ($V_{\text{molec}} = (4/3)\pi\sigma_{\text{molec}}^3$) when dividing by the Avogadro's number based on the value of b . In the **KINETIC THEORY** of gases the molecular diameter can be used to define the **VISCOSITY**: $\eta = 5/(16\sigma_{\text{molec}}^2)(m\kappa T/\pi)^{1/2}$, where κ is Boltzmann's constant, T the temperature of the gas, and m the mass of the molecule of the gas, assuming that the molecules behave as hard spheres.

Molecular dynamics

[computational] Theoretical study of the physical movement of atoms and molecules by means of simulation of an N -body interaction. The particulate (atoms and molecules) trajectories are derived from **NUMERICAL** solutions to Newton's **EQUATIONS OF MOTION** for a system of interacting units. The forces between the particulates and the acting potential **ENERGY** result from molecular mechanic force field definitions.

Molecular heat

[atomic, nuclear] Heat capacity per **MOLE** for a pure **ELEMENT** of material: amount of heat required to raise the temperature of 1 mole of a substance 1 K (*also see* **MOLAR HEAT** and **HEAT CAPACITY**).

Molecular motion

[nuclear] See **BROWNIAN MOTION**.

Molecular spectra

[atomic, nuclear] See **MOLECULAR SPECTROSCOPY**.

Molecular spectroscopy

[atomic, quantum, solid-state] Under atomic **SPECTROSCOPY** the examination can be based on a gaseous state under electric discharge that separates the atoms into neutral or charged atoms. Alternatively, the **GAS** may be molecular in composition and irradiated by an external excitation source of **ELECTROMAGNETIC RADIATION**. The molecules undergo **ENERGY** transitions based on **GROUND STATE** excitation or return. In general three excitation processes can be distinguished: electronic excitation, vibrational excitation, and rotational excitation, specifically due to the fact that the **MOLECULE** may be asymmetric. For a diatomic molecule the Hamiltonian (H) for the **MOTION** wavefunction approach can be written as (assuming that

the rotational excitation is relatively small compared to the first two):

$H = -(\hbar/2m_1)\nabla_1^2 - (\hbar/2m_2)\nabla_2^2 + V(r_{12})$, where ∇_i^2 is the second-order derivative with respect to the coordinates of nucleus 1 or 2 respectively, m_i the respective atomic/nuclear masses of the molecular constituents, $V(r_{12})$ the electric potential between the two components (both atomic and nuclear), and $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ Planck's constant. This will yield the following SOLUTION for the energy levels that can be identified by spectroscopic analysis: $E = (v_{\text{vib}} + 1/2)\hbar\omega + (J(J+1)\hbar^2)/2\mu_m r_0^2$, where $v_{\text{vib}} = 0, 1, 2, \dots$ the vibrational QUANTUM number, ω the vibrational frequency (the VIBRATION frequency can be associated with a "spring" phenomenon in molecular attraction), $J = 0, 1, 2, \dots$ the rotational QUANTUM number (with transition selection rule: $\Delta J = \pm 1$), $\mu_m = m_1 m_2 / (m_1 + m_2)$ the REDUCED MASS, and r_0 the average nuclear separation. A diatomic molecule can for instance be hydrogen chloride (see Figure M.123).

Figure M.123 Illustration of early design flame-spectroscopy device for use on molecular gasses, salts, and other chemicals.

Molecular weight

[thermodynamics] The sum of all atomic weights of the constituent atoms forming a MOLECULE.

Molecule

[atomic, biomedical, chemical, general, thermodynamics] The smallest chemical unit of material that has all the characteristics of the substance or ELEMENT in mass quantity (i.e., it can exist by itself while

retaining all the properties of the original homogeneous substance; see Figure M.124). The molecule consists of two or more atoms that are held together by covalent attractive forces to form a stable unit with no externally observable charges, the molecule is electrically and electronically neutral. The most well know molecules are oxygen (O_2) and WATER (H_2O).

Figure M.124 Graphical representation of the molecular structure of various hydro-carbon molecules.

Mollier chart

[thermodynamics] Graphical representation of the interconnecting relationships between temperature, moisture content, and respective entropy and enthalpy of composite gases, such as the ATMOSPHERE (composed of nitrogen, water vapor, oxygen and ozone, argon, neon, helium, methane, krypton, hydrogen, nitrous oxide, and xenon). The basic Mollier chart is used to plot the total heat against entropy. The chart was designed by the German physicist Richard Mollier (1863–1935) in 1904. The Mollier chart forms an elementary design tool to account for air–grain–moisture system in a malting process, refrigeration (performance analysis of VAPOR compression systems), and is also used by power station engineers in, for instance, the steam cycle. The chart shows ENTHALPY (H) with respect to internal ENERGY U , as well as

pressure P and volume V . The Mollier chart also applies to the Rankin cycle (*also see* PSYCHROMETRIC CHART, of which the Mollier diagram is a variant) (see [Figure M.125](#)).

Figure M.125 Mollier entropy chart for 410 refrigerant. (Courtesy of DuPont®.)

Molniya orbit

[astrophysics, general, mechanics] Highly eccentric orbit of Russian (USSR—Union of Soviet Socialist Republics) (in Russian: Союз Советских Социалистических Республик: “СРСС”) satellites at an azimuth inclination of 63.4° with orbital period of one-half of a sidereal day (sidereal time is based on the earth’s rate of rotation with respect to the fixed observable stars, used by astronomers to track the position of their TELESCOPE). These satellites have been in orbit since the 1960s. In Russian the word Molniya stands for “LIGHTNING.” In this configuration the SATELLITE spends the majority of time over the northern

hemisphere, reaching its highest orbital DISTANCE (apogee) of 40,000 km. For continuous coverage of the northern hemisphere a minimum of three Molniya satellites will be required. Satellites of this type can be used for communication as well as espionage (see [Figure M.126](#)).

Figure M.126 Representation of the Molniya orbit on postage stamp.

Moment arm

[biomedical] The perpendicular DISTANCE from line of force application with respect to the axis of rotation. This applies to the rotational MOTION of a joint in a biological vertebrate animal produced by the torque applied by musculoskeletal attachment, such as the elbow and the knee (see [Figure M.127](#)).

Figure M.127 The moment arm of the chimpanzee, proving a powerful lever, much stronger than the human elbow (a chimpanzee will easily overpower a human).

Moment coefficient

[fluid dynamics] Heuristic method used to quantify the aerodynamic forces on an object under FLUID flow conditions. The general form for a regular object (e.g., rod, WING, plate, or a bullet) is $C_m = \alpha_1 / (\text{Re}^{\alpha_2} [1 - \{\alpha_3 \text{Re}^{\alpha_4} \text{arcsinh}(\alpha_5 \text{Re}^{\alpha_6})\}])$, with α_i constants that are dependent on the conditions and shape and size, and Re is the REYNOLDS NUMBER of the object subjected to FLOW. For a sphere this yields $C_{m_{\text{sphere}}} = 8g / \text{Re}_{\text{sphere}}$, where $\text{Re}_{\text{sphere}}$ is the Reynolds number of the sphere in the flow, and g the GRAVITATIONAL ACCELERATION. The method is of particular relevance under transverse Blasius BOUNDARY LAYER flow. One specific example of interest refers to the aerodynamic aspect of a bullet in flight. There are several moments involved that describe the role, yaw and trajectory of a bullet, defined as follows: rolling moment coefficient— $C_{\ell} = \mathcal{L} / q S d$, where $\mathcal{L}$ is the rolling moment, S the cross-sectional surface area, q the kinetic pressure, and d the PROJECTILE diameter; SPIN dampening moment coefficient— $C_{\ell\phi} = \partial C_{\ell} / [\partial(\phi d / 2v)]$, where ϕ is the projectile spin rate, v the projectile velocity; overturning PITCH moment coefficient— $C_{m\phi} = \mathcal{M} / q S d$, where $\mathcal{M}$ is the overturning moment; Magnus moment coefficient slope— $C_{m\phi\beta} = \partial^2 C_{m\phi} / [\partial(\phi d / 2v) \partial \beta]$, where β is the ANGLE of sideslip; pitch DAMPING moment coefficient— $C_{mq} = \partial C_{m\phi} / [\partial(Q d / 2v)]$, where Q represents the overturning moment/pitch moment. In all cases the moment aspect refers to aspects of the MOMENT OF INERTIA and the MOMENT ARM (see Figure M.128).

Figure M.128 The concept of moment coefficient illustrated.

Moment of a force

[general] See TORQUE.

Moment of inertia (I_m)

[general, mechanics] Scalar quantity that provides a mechanism to describe the rotational MOTION response of a system of particles with nonuniform or uniform distribution in a geometric shape as the consequence of an external force with respect to a particular axis of rotation. The moment of inertia is defined as $I_m = \sum_i r_i^2 m_i$, in a reference frame of choice as summarized over all the masses ($\sum_i m_i = M$) (each respective mass (m_i) or finite mass ELEMENT dm) constituent identified by (m_i) as a function of each respective location

(r_i) contributed from a system of particles (regardless of size and structure; including atoms and molecules). In integral form $I_m = \int r^2 dm = \int \rho r^2 dV$, with ρ the local density and V the volume of the constituent at a respective location. In rotational KINEMATICS, the net TORQUE (τ) of all constituents of a revolving object around the axis of rotation is defined with respect to the moment of inertia and the angular acceleration (α) as $\Sigma \tau = I_m \alpha$ as the rotational counterpart to NEWTON'S SECOND LAW (see Figure M.129).

Specific examples of the moment of inertia of certain shapes with uniform density are as follows:

SHAPE	MOMENT-OF-INERTIA	SHAPE DRAWING
Circular annulus with inner radius R_1 and outer radius R_2 revolving around the central axis. With M the mass of the unit.	$I_m = M \frac{R_1^2 + R_2^2}{2}$	
Uniform right cone with maximum radius R_1 and length l revolving around the central axis. With M the mass of the shape.	$I_m = \frac{3}{10} MR^2$	
Uniform thin rod length l revolving around the axis through the center of mass, perpendicular to the central axis of the geometry.	$I_m = \frac{1}{12} M \ell^2$	
Uniform solid cylinder with radius R revolving around the central axis of the geometry.	$I_m = \frac{1}{2} MR^2$	
Uniform solid cylinder with length l and radius R revolving around the axis through the center of mass, perpendicular to the central axis of geometry.	$I_m = \frac{1}{4} MR^2 + \frac{1}{12} M \ell^2$	

Figure M.129 Moment of Inertia.

Moment of inertia (L), spin rate

[general, mechanics] In figure skating, the skater can retract the arms and/or an extended LEG, resulting in an increase in rotational velocity based on CONSERVATION OF ANGULAR MOMENTUM, since I_m is reduced with the diminished lengths of the components. The same principles apply to a merry-go-round, moving to and fro the edge changes the rotational angular velocity (see [Figure M.130](#)).

Figure M.130 Spin rate Moment of Inertia.

Momentum ($\vec{p}$)

[mechanics, nuclear] The fact that a body in MOTION tends to stay in motion is captured by the momentum of the body as the MASS (m) multiplied by the velocity (v) expressed as $\vec{p} = m\vec{v}$. More generally, the momentum of a massless entity can be captured as the rate of change (over time: t) in net ENERGY ($E = KE + PE$, where KE is the kinetic energy and PE the potential energy, respectively) as a function of velocity (v), expressed as $\vec{p} = dE/dv$. Under the conditions of NEWTON'S SECOND LAW a body will increase or decrease in momentum directly proportional to the applied net force (F), expressed as $\sum \vec{F} = d\vec{p}/dt$. Analogously, an ISOLATED SYSTEM will have conservation of momentum since no external forces are applied. There is a close relation with impulse, however, momentum generally provides a more useful concept. In PROPULSION with a gas-burning jet ENGINE, the mass of the object will vary (i.e., diminish: Δm), ejecting the propulsion waste with a velocity: $\vec{u}$ yielding the following condition involving the (conservation of) momentum: $d\vec{p}/dt = m(d\vec{v}/dt) - \Delta m(d\vec{v}/dt) + \vec{u}(dm/dt)$; note, there is no external force. (also see ANGULAR MOMENTUM). The product of the mass of a body and its velocity. CGS unit: gm-cm/s (see [Figure M.131](#)).

Figure M.131 The game of croquet illustrating the concept of Momentum, in specific the transfer of momentum.

Momentum change (Δp)

[general] In classical MECHANICS the change of momentum is the impulse: $J = \Delta p$ of a system. The change of momentum with respect to time is force ($F = dp/dt$) resulting from the change in momentum, applied to the phenomenon that made the momentum change; for instance, hitting a nail with a hammer over a short period of contact makes the hammer drive the nail into the wood, or a baseball fly into the outfield (see Figure M.132).

Figure M.132 How the change in momentum provides the force to drive a nail into a piece of wood.

Momentum eigenfunction

[atomic, fluid dynamics] In particle FLUX theory a free particle can be considered to be suspended by a constant potential V , that can be assumed $V = 0V$, which provides the one-dimensional SCHRÖDINGER EQUATION: $-(\hbar/2m)(d^2\Psi/dx^2) = E\Psi$, which yields a WAVE EQUATION solution $\Psi = Ce^{ikx} + De^{-ikx}$, and $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ Planck's constant, and E the particle ENERGY. In order for the PARTICLE to behave with constant momentum this solution is an EIGENVALUE function (i.e., EIGENFUNCTION) of the momentum operator: $p_{x_i} \rightarrow (\hbar/i)(\partial/\partial x_i)$, this will place as boundary conditions: $(\hbar/i)(\partial/\partial x)(Ce^{ikx}) = \hbar k Ce^{ikx}$ and $(\hbar/i)(\partial/\partial x)(De^{-ikx}) = -\hbar k De^{-ikx}$, which represents a particle with momentum $p_x = \hbar k$, with $k = 2\pi/\lambda$ the wavenumber of the eigenfunction with wavelength λ .

Monatomic gases

[general] Gases that consist of single atoms only, examples are all of the noble gases: argon (Ar), helium (He), krypton (Kr), neon (Ne), RADON (Rn), and xenon (Xe).

Mondeville, Henry de (1260–1320)

[biomedical, chemical, optics] (*See* **DE MONDEVILLE, HENRY**.) French physician. The work of De Mondeville is one of the first known documented descriptions of therapeutic applications of light, now known as photodynamic therapy, in the treatment of smallpox.

Monochromatic light

[general, optics] **ELECTROMAGNETIC RADIATION** of a single wavelength, such as produced by a laser. The mechanism of action of the light amplification process in **LASER** produces truly identical photons that are all traveling in **PHASE** (coherent) at one fixed wavelength. Due to **ENERGY** requirements, the production of monochromatic light is complex and cannot be achieved by filtration. Filtering light by spectral means such as a **PRISM** or a colored filter will provide light with a finite bandwidth that relies on the definition of the device used to select a specific wavelength range. Generally, filtering by any means will result in an exponential increase in device cost with decreasing waveband, reaching infinity for a single wavelength.

Monod, Jacques Lucien (1910–1976)

[biomedical, chemical] Biologist from France. Nobel Prize winner in 1965, Physiology or Medicine, with respect to the work on control of enzyme and virus synthesis in collaboration with François Jacob (1920–2013) and André Michel Lwoff (1902–1994), based on the discovery that the adjustment of enzyme concentrations in all biological cells occurs through regulation of transcription; the first step of gene expression, transcribing DNA onto RNA by means of RNA polymerase enzyme (see [Figure M.133](#)).

Figure M.133 Jacques Lucien Monod (1910–1976). (Courtesy of Memorial University of Newfoundland.)

Monod equation

[biomedical, chemical] Mathematical description of microorganism growth rate, described by **JACQUES LUCIEN MONOD** (1910–1976) in 1949. The equation describes the growth of microorganisms based on the maximum specific growth rate ($\mu_{\text{Growth}}^{\text{Max}}$), the concentration of the enzyme substrate that initiates the growth process ($[S_{\text{substrate}}]$), and an empirical “half-velocity” constant defining the conversion process ($K_{\text{conversion}}$, the Monod constant; the concentration of $[S_{\text{substrate}}]$ at “half growth”: $\mu_{\text{Monod}}/\mu_{\text{Growth}}^{\text{Max}}$) as $\mu_{\text{Monod}} = \mu_{\text{Growth}}^{\text{Max}} ([S_{\text{substrate}}] / ([S_{\text{substrate}}] + K_{\text{conversion}}))$.

Monolayer

[fluid dynamics, general, solid-state] Steady-state or FLUID dynamic single uniform one MOLECULE thick film, or layer of closely packed atoms, molecules, or cells at an interface. In FLUID DYNAMICS the monolayer forms a BARRIER between the free FLOW and the rigid or semirigid wall. The WALL may be the surface on the wing of an airplane, or the inner perimeter of a tube or BLOOD vessel. Monolayers can consist of, for instance, but not limited to lipids, nanoparticles, polymers, and proteins. Surfactants will also form a monolayer (e.g., soap). Also known as Langmuir film (see [Figure M.134](#)).

Figure M.134 Illustration of the monolayer concept with regard to soap (detergent/surfactant).

Monolithic

[electronics, general, geophysics] Geological single feature consisting of a stone or rock formation, for instance, a mountain. In semiconductor manufacturing, the monolithic layer is composed of a homogeneous ceramic or composite structure of several nanometer to micrometer thickness, with specific electronic and electromagnetic properties, potentially used to produce light through an excitation process, for instance, in customized LED development.

Monolythic

[electronics, general, geophysics] See MONOLITHIC.

Monomer

[biomedical, chemical] Single molecule. This MOLECULE may bind to other molecules to form a POLYMER, often used in the description of protein structures; e.g., monomeric protein. One example of a common

monomer is glucose, found as a building block in plant MATTER (77%) and related as essential food constituent for human consumption. Glucose form a polymer when bond by glycosidic bonds to form CELLULOSE and starch. Another example is vinyl chloride, which is the monomer that form the synthetic POLYMER POLYVINYL CHLORIDE (PVC) (see [Figure M.135](#)).

Figure M.135 Structural chemical formulas of 20 basic monomer amino acids.

Monopole, magnetic

[general] Hypothetical particle or magnetic segment within a medium, that consists of only a NORTH or south pole, as such assigned with a “magnetic charge.” In practice this is inconceivable since MAGNETIC FIELD lines are by definition forming a closed loop. The theoretical concept originates from hypothetical concepts such as the GRAND UNIFIED THEORY.

Monopole antenna

[general] Mast ANTENNA that uses GROUND as a MIRROR to produce a virtual bipolar source. The monopole antenna requires half the voltage to produce the same field intensities as a free-space bipolar antenna.

Monte Carlo integration

[computational] Special technique in Monte Carlo methods used for NUMERICAL integration using random numbers based on PROBABILITY of events and associated magnitudes.

Monte Carlo method

[computational] Numerical technique for simulating analog processes based on PROBABILITY distribution of phenomena with certain distributions in MAGNITUDE with the assistance of random number generation to select specific events in the probability distribution on the fly. Monte Carlo simulation allows to account for risks process analysis in quantitative analysis and decision making, providing a range of possible effects and results with the associated probabilities that this will occur as the result of a particular choice of action. The Monte Carlo technique is used in ENERGY estimates and predictions, ENGINEERING, environmental predictions, finance, insurance, manufacturing, project management, research and development, transportation, and the utilities (e.g., oils, GAS) (see [Figure M.136](#)).

Figure M.136 Illustration of the random number distribution used in Monte Carlo modeling, roulette game-of-chance.

Montgolfier, Jacques-Étienne (1745–1799)

[engineering, general] Scientist and inventor from France. Together with his brother JOSEPH-MICHEL MONTGOLFIER (1740–1810) they started the design of the MONTGOLFIER-STYLE HOT-AIR BALLOON, approximately in 1777 (see [Figure M.137](#)).

Figure M.137 Montgolfier brothers, Jacques-Étienne Montgolfier (1745–1799) and Joseph-Michel Montgolfier (1740–1810).

Montgolfier, Joseph-Michel (1740–1810)

[engineering, general] Scientist and inventor from France. Together with his brother JACQUES-ÉTIENNE MONTGOLFIER (1745–1799) they launched the MONTGOLFIER-STYLE HOT-AIR BALLOON, approximately in 1782.

Montgolfier-style hot-air balloon

[engineering, general] Hot-air balloon that served as the basis for the modern hot-air balloon introduced by the two brothers JOSEPH-MICHEL MONTGOLFIER (1740–1810) and JACQUES-ÉTIENNE MONTGOLFIER (1745–1799) from France at first ascent in 1782. The first manned balloon ride was performed in 1783 and subsequently a presentation was made to King Louis XVI of France (1754–1793) and Queen Marie Antoinette Josephina (1755–1793) from Austria (see [Figure M.138](#)).

Figure M.138 Montgolfier hot-air balloon.

Moody diagram

[fluid dynamics] Graphical tool to estimate the FLUID dynamic friction coefficients in FLOW. The derived FRICTION coefficients are also known as MOODY FRICTION FACTOR. The Moody friction factor (found as either λ_{Moody} or f_{Moody}) is a major component in the Darcy–Weisbach major loss equation (see Figure M.139).

Figure M.139 Moody diagram providing a plot of the Darcy–Weisbach friction factor against Reynolds number for a range of roughness conditions. (Courtesy of S. Beck and R. Collins, University of Sheffield.)

Moody friction factor

[fluid dynamics] Coefficient of FRICTION for FLUID flow, with respect to conduit conditions. The Moody friction coefficient is a complex function of the REYNOLDS NUMBER and relative roughness. Also found as Darcy–Weisbach friction factor.

Moon

[astrophysics, general] Celestial body in stable orbit around a larger planetary object. The EARTH has one Moon at an average DISTANCE of 384,400 km (apogee: 405,503 km), with distinct crust, mantle, and core, all with geochemically well-defined compositions and total mass of 7.3477×10^{22} kg. The earth's Moon influence the tidal rise and fall due to gravitational interaction. Certain planets have more than one Moon; for instance, MARS has two moons and JUPITER, NEPTUNE, SATURN, and URANUS each have several moons. Generally moons can also be referred to as (natural) satellites. The earth's Moon has been described in the greatest detail due to its proximity and centuries of observation. Our Moon has several phases of observation; ranging from new Moon to full Moon, with waxing from new to first quarter to full and waning to new, passing the last quarter. The observation of the Moon and its size relative to its position in the sky was described as far back as documented history reveals to the seventh century BC, providing an optical

focusing and magnification by the Earth's ATMOSPHERE when close to the horizon. The Moon ORBITS the Earth in an elliptic plane, approximately in 27.3 days, with respect to the fixed stars, or about Earth 29.5 days, as described by CASSINI's LAWS. The Moon itself has an equatorial rotation velocity of 4.627 m/s, synchronous with the PLANET Earth. Generally, same side of the Moon always faces Earth (the "near side of the Moon"), with the consequent preverbal "dark side of the Moon"; however, this "far side of the Moon" does receive equal proportions of solar exposure (*also see* PHASE OF THE MOON) (see [Figure M.140](#)).

(a)

(b)

Figure M.140 (a) Moon as seen from the northern hemisphere (Courtesy of NASA) and (b) Moon phases in reference to the illumination by the Sun with respect to the position of the Moon to the Sun in the orbit around Earth as well as around the Sun while Earth revolves around the Sun.

Moore, Earle Gordon (1929–)

[computational, general, quantum] An American scientist and the founder and chairman emeritus of the Intel Corporation (a leading manufacturer of MICROPROCESSOR chips for computers, founded in 1968). His work in CHIP design prompted him to coin the statement about the technological increase in computing power, known as MOORE'S LAW, introduced in 1965 (see [Figure M.141](#)).

Figure M.141 Earle Gordon Moore (1929–). (Courtesy of Intel Corporation, Santa Clara, CA.)

Moore's law

[computational, general, quantum] Statement by EARLE GORDON MOORE (1929–) (Intel Corp.) in 1970 relating the technological advancement in MICROPROCESSOR design with respect to the perceived processing speed with 18 month increments of 200%. The alternate interpretation relates the increase of the number of TRANSISTOR components integrated on a processor CHIP in the same manner, double every 18 months to 2 years, which has been reliably appropriate for more than two decades since the first proclamation in 1965. The incremental increase of transistors is directly related to the ever reducing size of electronic hardware. In practicality, the processor power of the computer board is close to double every year at this point.

Morgan–Keenan luminosity classes

[astronomy] Classification of stars by order of luminous radiance: Ib: Supergiants; II: Bright Giants; III: Giants; IV: Subgiants; V: Main-Sequence Stars (*also see* LUMINOSITY FUNCTION *and* HERTZSPRUNG–RUSSELL DIAGRAM) (see [Figure M.142](#)).

Figure M.142 Diagram of Morgan–Keenan luminosity classes, with the guiding reference: $R_{\odot}$, the radius of our Sun.

M

Morley, Edward Williams (1838–1923)

[general, optics] Scientist, physicist, and chemist as well as theologian, born in the United States. Morley is most known for his work in OPTICS and general PHYSICS as well (*see* MICHELSON–MORLEY EXPERIMENT) (see [Figure M.143](#)).

Figure M.143 Edward Williams Morley (1838–1923).

Morse, Harmon Northrop (1848–1920)

[chemical, thermodynamics] Chemist from the United States. Morse introduced refinements to the VAN'T HOFF EQUATION for OSMOTIC PRESSURE under the MORSE EQUATION. Additional work on the pressure effects of solutes was presented by ERNEST STARLING (1866–1927).

Morse, Philip McCord (1903–1985)

[chemical, computational, solid-state] Physicist born in the United States. Philip Morse derived the MORSE POTENTIAL for a harmonic oscillator, specifically applied to the nuclear forces in a diatomic MOLECULE (see [Figure M.144](#)).

Figure M.144 Philip McCord Morse (1903–1985), in 1972. (Courtesy of Massachusetts Institute of Technology [MIT] Web-Museum.)

Morse, Samuel Finley Breese (1791–1872)

[theoretical] Artist and painter from the United States who was also an inventor. In collaboration with the American physicist known for the discovery of self-induction, JOSEPH HENRY (1797–1878), and American mechanical engineer Alfred Vail (1807–1859), the TELEGRAPH system was developed as well as the communication mechanism, referred to as MORSE CODE (see [Figure M.145](#)).

Figure M.145 Samuel Finley Breese Morse (1791–1872) in 1840, photographer potentially Louis Jacques Mandé Daguerre (1787–1851).

Morse code

[theoretical] Pulse pattern of long and short duration pulses that represent letters in the alphabet as well as numbers. Morse code was (and still is) easily transmitted by optical, mechanical, and electronic means over great distances. The coding mechanisms is constructed of combinations of pulses with different duration, referred to as dashes and dots. The duration of a dash is three times the duration of a dot. The principle dates back to approximately 1836, where the collaborative effort of an artist Samuel F. B. Morse, physicist JOSEPH HENRY (1797–1878), and mechanical engineer Alfred Vail (1807–1859) developed an electric TELEGRAPH system. The telegraph system was designed to send electric pulses along wires leading to an ELECTROMAGNET that generated a tapping SOUND under the influence of the electric pulses. Samuel Morse developed a code based the duration and the silence between pulses, to convey messages. The Morse code is resilient against many NOISE factors and can be recognized even under low SIGNAL strength. Morse code only

requires a single wire for transmittance of information. The most well-known Morse code sequence is for S-O-S (save our souls; distress call) (see [Figure M.146](#)).

Figure M.146 (a) Morse code encryption scheme and (b) picture of person operating Morse-code apparatus with finger tapping, transmitted via telegraph system and wiring.

Morse equation

[chemical, thermodynamics] COLLOID OSMOTIC PRESSURE (Π) description formulated by HARMON NORTHROP MORSE (1848–1920), expressed as a function of the molarity of the SOLVENT ($[M]$), defined at a specific temperature (T) as $\Pi = i_{vH} [M] RT$, where i_{vH} is the VAN'T HOFF FACTOR (i.e., degree of dissociation: $i_{vH} = 1 + \alpha_{\text{dis}}(n-1)$, where α_{dis} is the fraction of the original molecules of the SOLUTE that have dissociated and n the number of ions/atoms/molecules in the dissociation product), and $R = 8.3144621(75) \text{ J/Kmol}$ the universal GAS constant.

Morse potential

[atomic, chemical, computational, nuclear solid-state, thermodynamics] A simplified diatomic potential expression, constructed from the Rydberg–Klein–Rees (RKR) curves, derived by PHILIP MCCORD MORSE (1903–1985). The Morse potential ($U(r-r_e)$) is expressed as $U(r-r_e) = D_e \left(1 - e^{-\beta(r-r_e)}\right)^2$, where D_e is the dissociation ENERGY (which is the nuclear potential minimum), r_e is the equilibrium DISTANCE between the respective nuclei of the diatomic molecule, and β is a correction factor for the dissociation energy and is related to the REDUCED MASS of the MOLECULE in addition to the resonance frequency harmonics ω_e . The

RESONANCE FREQUENCY of the atomic bond is ruled by a Hook's law type force as $E_\psi = (1/2\pi c)\sqrt{k/\mu_m}(\psi + (1/2)) = \omega_c(\psi + (1/2))$, where E is the energy of VIBRATION, ψ is the vibrational quantum number (integers), k the molecular spring constant, c the speed of light, and μ_m the reduced mass of the molecule with ATOM constituents A and B : $(1/\mu_m = (1/m_A) + (1/m_B))$. The modes of OSCILLATION are as follows: rotation, scissor, translation, and vibration (EXPANSION/contraction). Also known as the potential energy of a diatomic molecule. Equation derived by Philip Morse as a function of the separation between the atoms (r) as $(V(r) = D_{\text{well}}(1 - e^{-a_{\text{well}}(r-r_{\text{eq}})})^2)$, where D_{well} is the well depth, r_{eq} the diatomic equilibrium distance, and $a_{\text{well}} = \sqrt{(k_{\text{well}}/2D_{\text{well}})}$ is the parameter that defines the width of the POTENTIAL WELL, with k_{well} the "spring constant" at the minimum of the well (smaller value of a_{well} corresponds to a larger well) (see Figure M.147).

Figure M.147 Graphical representation of the Morse Potential.

Morton number ($Mo_{\text{Liquid}} = g\eta_f^4\Delta\rho/\rho_f^2\sigma^3 = We^3/FrRe^4$)

[computational, fluid dynamics] Dimensionless number that characterizes the size and shape of a droplet or BUBBLE, specifically when used together with the Eötvös number. In this definition we have the following parameters: g the GRAVITATIONAL ACCELERATION, η_f is the FLUID viscosity of the ambient medium, ρ_f the density of the ambient medium, $\Delta\rho$ the difference in DENSITY (ρ) between the LIQUID and GAS PHASE, and σ the SURFACE TENSION coefficient. Additionally, the following DIMENSIONLESS NUMBERS have been inserted: We the Weber number, Fr the Froude number, and Re the REYNOLDS NUMBER.

Moseley, Henry (Harry) Gwyn Jeffreys (1887–1915)

[atomic, nuclear] Physicist from Great Britain. Introducer of the concept of the atomic number in 1915, identifying the quantity of protons in the NUCLEUS of an ATOM, hence indicating the total positive ELECTRIC CHARGE of the nucleus. Moseley performed additional groundbreaking experimental work on X-ray SPECTROSCOPY and implementing BRAGG'S DIFFRACTION law to describe the atomic and crystalline structure of ELEMENTS and their natural occurrence. Bragg's diffraction law was developed by the British father-and-son team SIR WILLIAM HENRY BRAGG (1862–1942) and WILLIAM LAWRENCE BRAGG (1890–1971), for which

they received the Nobel Prize in Physics in 1915. Moseley described the relationship between the ATOMIC NUMBER (Z) and the emission wavelength in X-RAY under CATHODE ray exposure, known as MOSELEY'S LAW (see [Figure M.148](#)).

Figure M.148 Henry (Harry) Gwyn Jeffreys Moseley (1887–1915).

Moseley diagram

[atomic, nuclear] Plot of the square root of the emission frequency of the K and L lines against the atomic number (initially a chosen integer, later connect to the atomic number by Moseley) produces a set of (almost) straight lines resulted. HENRY (HARRY) GWYN JEFFREYS MOSELEY (1887–1915) devised an apparatus for bombarding samples with electrons, of all the ELEMENTS available at the time (early 1900s) ranging from aluminum to gold and measuring the emission wavelengths (in the X-RAY), and hence the frequencies, in the spectra for the respective elements. The diagram allowed for X-ray-based identification of elements. Moseley also “discovered” certain elements that should be in the graph, since there were voids indicating new elements. The square root dependency could be explained by the Bohr theory (see [Figure M.149](#)).

Figure M.149 Moseley diagram with frequency versus proton number (Z ; atomic number). Electrons falling from the K-shell (lowest shell, highest binding energy) produce X-ray radiation known as K-series radiation: K_α , K_β , K_γ respectively, while the second level: L produces an L-series spectrum.

Moseley's law

[atomic, electromagnetism, general, nuclear] Frequency (ν) of the α -line or main K-line (K-ALPHA LINES) in X-RAY emission following the ENERGY pattern described in the BOHR ATOMIC MODEL based on the atomic number Z , designating the number of protons in the NUCLEUS, as developed by HENRY (HARRY) GWYN JEFFREYS MOSELEY (1887–1915) expressed as $\nu = [k_1(Z - k_2)]^2 = 2.476 \times 10^{15} (Z - 1)^2 H\zeta$, where k_1 and k_2 are emission line-dependent constant, which are equal for any $K\alpha$ -line. The value of k_1 changes for the transitions from the L-shell or the M-shell (smaller value for orbits farther out, by order of MAGNITUDE each time). For the K-line $k_1 = (3cR_y/4)^{1/2}$, c the speed of light, $R_y = 1.097 \times 10^7 \text{ m}^{-1}$. The RYDBERG CONSTANT is also known as Moseley's rule.

Mössbauer effect

[nuclear] Special phenomenon in nuclear resonance FLUORESCENCE under conditions of recoil-free GAMMA RAY absorption and emission. The phenomenon was recognized by Rudolf Ludwig Mössbauer (1929–2011) and described in 1958. The collision-free RESONANCE is established by initiating nuclear excitation by means of beta-decay, while simultaneously re-exciting another NUCLEUS of the same species in a resonance scheme, specifically using a collimated beam. Hypothetically, the emitter nucleus and the resonant target nucleus are refrained from movement. This approach relies on the fact that the ENERGY configuration of the process has a line width of $\Gamma^* = \lambda/2\pi\tau_{\text{life}}$, where τ_{life} is the average lifetime of the excited nuclear state and λ the wavelength of the gamma DECAY, with associated (relatively large) interaction CROSS SECTION $\sim (\lambda/2\pi)^2$, and note that the PHOTON carries a momentum: $p = E/c$, where $E = h\nu$ is the photon energy for frequency ν and $c = 2.99792458 \times 10^8 \text{ m/s}$, the speed of light. The realistic manifestation of this principle is emission as a mixture of resonant idealized and unconstrained spectrum. The idealized case has no nuclear motion, which is not easily (not realistic) achieved, while the unconstrained case where there is recoil resulting from the absorption of the QUANTUM momentum (see [Figure M.150](#)).

Figure M.150 Mössbauer effect.

Motility

[biomedical, computational, energy, general, mechanics] Capability of moving under the consumption of ENERGY, or having the power to move spontaneously (under a biological fuel system), in particular for unicellular biological life forms, such as spores or sperm. Even though the principle applies to all forms of

life, the specific interests are in the unicellular and simple multicellular organisms. Additionally, motility also refers to the ability of an organism to transport food through the digestive tract. Examples of the food transportation are the PERISTALTIC MOTION of the intestines and esophagus (see [Figure M.151](#)).

Figure M.151 The motility of a bacterial cell by means of flagella.

Motion

[astrophysics, atomic, biomedical, computational, energy, general, geophysics, mechanics, thermodynamics] Movement of objects in linear displacement, revolution or rotation, or VIBRATION and combinations of these such as PRECESSION. Motion can be split into two topic headings: KINEMATICS and DYNAMICS. Motion around the center of mass becomes rotation, whereas linear free-space MOTION falls under ballistics. Harmonic (vibrational) motion is widely found in many applications (mass-spring concept) as well as in atomic and molecular ENERGY configuration. Motion requires an initial force, or a sustaining force (see [Figure M.152](#)).

Figure M.152 Motion, skateboarded using the muscles in the leg to apply force to the ground to advance the board occupied by the mechanism of motion.

Motional feedback loudspeaker

[acoustics, electronics, fluid dynamics, mechanics] Acoustic emission device with feedback mechanism to modulate the frequency profile and enhance durability. Process developed and implemented in LOUDSPEAKER devices by Philips Electronics, Best, the Netherlands (see [Figure M.153](#)).

(a)

(b)

(c)

Figure M.153 Design and mechanism of operation for the motional feedback loudspeaker. (a) Inside view of feedback electronics within speaker box. (b,c) Piezoelectric pick-up on loudspeaker for feedback mechanism.

Motor

[general] Mechanical device that can perform work and is powered by an ENERGY source. Examples are combustion ENGINE, direct- (DC) and ALTERNATING CURRENT (AC) (electro-) motor, and wind-powered engines. Frequently the class of electromotors is the only group and energy source used to describe motor function. *Electric motors* operate based on any of the following three principles: magnetic, electrostatic, and piezoelectric; which are all physically different in providing the MOTION. The most common mechanism of action is MAGNETIC (see [Figure M.154](#)).

Figure M.154 Electromotor design, in comparison to an electrical generator.

Mott, Nevill Francis, Sir (1905–1996)

[nuclear] Scientist from Great Britain. In 1977, Mott won the Nobel Prize for Physics. Mott investigated the electronic structure of MAGNETIC systems. The special focus of Mott's work was on disordered systems, in particular amorphous SEMICONDUCTORS. Mott shared the Nobel Prize with PHILIP WARREN ANDERSON (1923–) and John Hasbrouck Van Vleck (1899–1980), who worked on similar projects and sometimes collaborated as well (see [Figure M.155](#)).

Figure M.155 Sir Nevill Francis Mott (1905–1996).

Moving coil galvanometer

[general] CURRENT (I) measuring device that uses a coil with N windings placed between two permanent magnets with MAGNETIC FIELD B . The torque on the coil as a function of the current passing through the coils will change the direction of a dial as an ANGULAR DISPLACEMENT (θ) attached to the coil as $I = (k/NAB)\theta$, where k is the spring constant that prevents the coil from rotating under the force, applied by a rotating spring with force $F = k\theta r$, where r is the LEVER arm of the attachment of the spring to the coil.

M-phase

[biomedical, energy] The mitotic biological CELL division process which is composed of mitosis and cytokinesis, before the G_1 -phase and after G_2 - and S -phases. M-phase consists of producing two identical cells in a process starting out from one cell starting in the G_1 -phase; also known as the telophase. During mitosis, the organization of the cell becomes physically representative of the final mature cell (G_1 -phase), the chromosomes are recoiling after they have split and reproduced in S -phase. The cell division process is preceded by a nutrient intake episode called the interphase. Cells not in cell division are in a dormant or quiescent stage, also referenced as G_0 -phase. The entropy and internal ENERGY (i.e., Gibbs energy) of the cell changes with the changes in cell division (see Figure M.156).

Figure M.156 M-phase in cell mitosis (cell-division), telophase; in the process starting from Prometaphase, into prophase, followed by interphase and metaphase with the anaphase culminating in the telophase.

MRI

[imaging] See MAGNETIC RESONANCE IMAGING.

Mu meson

[nuclear] See MUON.

Multiparameter inversion

[acoustics, computational, geophysics, solid-state] Wave propagation in anisotropic elastic media can be modeled by assuming perturbations to a homogeneous, single format medium, the background model.

Mathematically, the SCATTERING of the propagating waves can be approximated by implementation of a location specific pseudodifferential operator that mimics the discontinuities in the background model. The field perturbations are described by the model vector $\vec{m} = (m_1, \dots, m_n)$, consisting of n material component parameter perturbation fields m_i . The applied field of operators, expressed as a matrix.

$$[N_{\text{opp}}] = \begin{bmatrix} N_{\text{opp}}^{11} & \dots & N_{\text{opp}}^{1n} \\ \vdots & \ddots & \vdots \\ N_{\text{opp}}^{n1} & \dots & N_{\text{opp}}^{nn} \end{bmatrix}$$

yields: $[N_{\text{opp}}] \vec{m} = \vec{m}_{\text{mig}}$. The resulting migration output vector: $\vec{m}_{\text{mig}}$ contains “images” of the WAVE due to perturbations. The observed data (d_{obs}) are linked to a migration operator ($[F_{\text{opp}}]$) as $[F_{\text{opp}}] \vec{m} \approx \vec{d}_{\text{obs}}$, where $[F_{\text{opp}}][F_{\text{opp}}]^* \vec{m} = [F_{\text{opp}}]^* \vec{d}_{\text{obs}}$, with $[F_{\text{opp}}]^*$ the transposed (adjoint) matrix of $[F_{\text{opp}}]$.

Multiple linear regression

[computational] The multiple regression forms an EXPANSION to modeling the relationship between a single or functional variable: x (i.e., explanatory variable) to a SCALAR dependent variable y to include two or more explanatory variables, yielding a three-dimensional relationship.

Multiple photon photoelectric effect

[general] Multiphoton interaction can yield the sum of the ENERGY of the interacting photons, thus acting as if a shorter wavelength single PHOTON created the interaction. The PHOTOELECTRIC EFFECT is generally more effective with higher efficiency at shorter wavelength ELECTROMAGNETIC RADIATION. The multiphoton effect can be achieved under high-power density irradiation, increasing the PROBABILITY of simultaneous photon interaction on an atomic or molecular level.

Multiplication factor

[atomic, nuclear] In the general operations of a nuclear reaction, the reaction will need to be self-sustaining, which involves causing on an average more than one nuclear reactions. The multiplication factor, ν_{neutron} , is the average number of neutrons generated by one FISSION that will initiate another fission, the effective NEUTRON multiplication factor. It is also known as neutron multiplication factor. For $\nu_{\text{neutron}} < 1$, the REACTOR will not sustain a CHAIN REACTION, and is considered subcritical; whereas for $\nu_{\text{neutron}} > 1$ the reactor can go beyond the point of control by the controller bars and moderator bars and is generally considered supercritical (*also see MODERATOR BAR*).

Multiplicity of spectra

[atomic, nuclear, quantum] The multiplicity of spectral lines ($\mathcal{M}_{\text{spectral}}$) for atomic spectral analysis is based on quantum PHYSICS principles on atomic or molecular level. The phenomena of multiplicity of spectral lines applies both to OPTICS and magnetic resonance imaging (MRI). Optically, the principles rely on atomic excitation, specifically the SPIN orientation of the transitions: $\mathcal{M}_{\text{spectral}} = 2\Sigma + 1$, where Σ is the sum of all the spins s and is consistently the number of VALENCE electrons for specific ELEMENTS plus 1, such as POTASSIUM (K), calcium (Ca), scandium (Sc), and vanadium (V). For calcium, this provides an EMISSION SPECTRUM of singles and triplets due to the valence of 2. In NUCLEAR MAGNETIC RESONANCE (NMR) imaging, the same multiplicity applies to the PROTON resonance spectral lines, providing singlet, DOUBLET, triplet, quartet, and so on RESONANCE frequencies. In this case the spectra of a given NUCLEUS follows from spin coupling, specifically coupling to Σ number of equivalent nuclei. In the latter case, the coupling to equivalent nuclei raises the concept of equivalent ligands and uses Pascal's triangle to form the splitting pattern. For instance, 1,1,2-tribromoethane

($\text{C}_2\text{H}_3\text{Br}_3$) has two identical hydrogen nuclei, with concomitant two NMR peaks, one with multiplicity three ($\Sigma = 2 + 1 = 3$, i.e., three resonant lines— H_3 —the peak has three lines; from the Pascal's triangle, it is a triplet), and one with multiplicity two (2; since H_1 and H_2 act equivalently) (see [Figure M.157](#)).

Figure M.157 Molecular bond configuration in 1,1,2-tribromoethane ($\text{C}_2\text{H}_3\text{Br}_3$) that can provide the mechanism to support Multiplicity of Spectra due to the ambivalence of the energy structure.

Multiplier tube

[atomic, nuclear, optics] See **PHOTON MULTIPLIER TUBE**.

Multipole

[computational, electromagnetism, solid-state, thermodynamics] Model of a symmetric periodic system by the sum of sines and cosines in the form of a **FOURIER SERIES** with the necessary parameters (the multipole moments) or as a set of Legendre polynomials in a spherical coordinate system. One example of the use of multipoles in approximations is applied to predicting the electric potential field due to a complex molecule by eliminating the contributions of all the respective atoms (which can become an elaborate task, specifically including the interatomic fields) and decomposing the molecule in a few multipole moments as a reasonable approximation. Examples are monopole, **DIPOLE**, quadrupole, octupole, and so on. Multipoles can provide an acceptable impression of how the field behaves, without the need to know the exact fundamental field.

Multipole moment

[nuclear] The collection of necessary parameters to define the coefficients in the **FOURIER SERIES** and the Legendre polynomials for the description of multipoles.

Multipole radiation

[computational, nuclear] Description of electromagnetic or gravitational radiation resulting from perturbations in the distribution of sources in a time-dependent system. This theoretical mechanisms can describe phenomena ranging from **GRAVITATIONAL WAVES** to gamma radiation due to nuclear **DECAY**.

Muon

[astronomy/astrophysics, atomic, general, nuclear, quantum, thermodynamics] Elementary **MESON** particle in the category of **LEPTON**, unstable but behave very similar to electrons, although with much greater mass. The muon, discovered in 1938, has a mass-equivalent **ENERGY** of $E = mc^2 = 106 \text{ MeV}$. The discovery of the muon

resulted from studying COSMIC RAYS. Generally, two types of muons can be recognized, with opposite charge, each decaying according to a specific path, into ELECTRON (e^-) or POSITRON (e^+) according to their nature, and two neutrinos according to the following rules: $\mu^+ \rightarrow e^+ + \nu_e + \bar{\nu}_\mu$ or $\mu^- \rightarrow e^- + \bar{\nu}_e + \nu_\mu$, where ν_e and ν_μ are neutrinos and anti-neutrinos ($\bar{\nu}_\mu$; $\bar{\nu}_e$), respectively, the lifetime of a muon is approximately 2 μ s (see Figure M.158).

Figure M.158 (a) Placing the muon in the scheme of elementary particles and (b) muon decay mechanism.

Murray's law

[biomedical, fluid dynamics] In hemodynamic flow there should be certain design constraints that provide conditions to ensure minimization of ENERGY requirements to maintain fluid transport. In BLOOD CIRCULATION the work performed is dependent on, but not limited to, the HEART muscle contraction, vascular COMPLIANCE as well as Bernoulli pressure gradients. Specifically with respect to vascular radius, there is an optimum in the work performed (minimal), balancing work, and momentum (p). The momentum is linked to the FLOW with (average) velocity (v or rather v_{avg} across the vessel diameter) as $p = mv \sim [d(m\dot{x})/dt]$, where the MASS (m) of liquid in a segment of vessel with radius (r) and cross-sectional area (A_{cross}) is changing over time based on the vascular compliance: $\dot{m} = dm/dt = \rho_{\text{fluid}} v_{\text{avg}} A_{\text{cross}}$ where blood is an INCOMPRESSIBLE FLUID and hence the density: $\rho_{\text{fluid}} = \text{const}$. The minimum work associated with flow is defined by Murray's law as the vascular radius for which the following hold true: $dW_{\text{tot}}/dr = 0$, where the total power exerted by the circulation $W_{\text{tot}} = W_{\text{flow}} + W_{\text{blood}}$ is the sum of the power to maintain flow W_{flow} and the effort involved in maintaining blood supply: W_{blood} . The blood flow obeys the POISEUILLE'S LAW: $W_{\text{flow}} = Q\Delta P = 8\ell Q^2 \eta_{\text{visc}} / \pi r^2$, where Q is the flow, ΔP the pressure gradient of length ℓ for a FLUID with VISCOSITY η_{visc} . The "creation of blood" relies on the synthesis of proteins and additional biological processes, which can be captured by the ARRHENIUS EQUATION: $W_{\text{blood}} = \alpha_{\text{blood}} \nabla_{\text{blood}}$, with α_{blood} the production energy for one unit of blood, and $\nabla_{\text{blood}} = \pi r^2 \ell$ the volume of blood.

Muscle

[biomedical, chemical, electromagnetism, mechanics] Mechanical MOTOR function of biological units. In humans three different kinds of muscle can be distinguished: cardiac (in the HEART), skeletal (attached to JOINTS and bone), and smooth (e.g., in the WALL of veins [multiunit] and in the reproductive system as well as the digestive system [visceral]). SKELETAL MUSCLE is connected to bone through cartilage, with seamless integration between the various biological components; the tendon integration with muscle is achieved by aponeuroses (broad fibrous sheets). Muscular contraction is a digital phenomenon. Higher frequency of pulses sent by the motor unit to the muscle increases the contraction. The motor unit itself is stimulated by the brain or through autonomic regulation. This means that the motor unit may act independently, irrespective of will power (see [Figure M.159](#)).

Smooth muscle

Skeletal muscle

Cardiac muscle

Figure M.159 (a). Types of muscles: from left to right represented by histological view: smooth, skeletal, and cardiac (Courtesy Dr. S. Girod, Anton Becker.) and (b) diagram of a motor unit.

Muscle, anatomy

[biomedical, chemical, electromagnetism, mechanics] A **SKELETAL MUSCLE** fiber is a thin elongated cylinder with rounded ends and may extend the full length of the muscle. Beneath its sarcolemma (**CELL MEMBRANE**), the cytoplasm or sarcoplasm of the fiber contains many small, oval nuclei and mitochondria. Within the sarcoplasm are numerous threadlike myofibrils that lie parallel to one another. They play an important role in muscle contractions. The myofibrils contain two kinds of protein filaments: (1) thick ones composed of the protein **MYOSIN** and (2) thin ones composed of the protein **ACTIN**. The arrangement of these filaments in repeated units are called sarcomeres, which produce the characteristic alternating light and dark striations of muscles. Light areas are the I-bands and the darker areas are A-bands. Z-lines are where adjacent sarcomeres come together and thin myofilaments of adjacent sarcomeres overlap slightly. Thus, a **SARCOMERE** can be defined as the area between Z-lines. Myosin filaments are located primarily within the dark portions of the sarcomeres, while actin filaments occur in the light areas. Within the cytoplasm of a muscle fiber is a network of membranous channels that surround each myofibril and runs parallel to it, which is the sarcoplasmic reticulum. Transverse tubules (t-tubules) extend inward from the fiber's membrane. They contain extracellular **FLUID** and have closed ends that terminate within the light areas. Each t-tubule contacts specialized enlarged portions (cisternae) of the sarcoplasmic reticulum near the region where the actin and myosin filaments overlap. These parts function in activating the muscle contraction mechanism when the fiber is stimulated. Each skeletal muscle fiber is connected to a fiber from a nerve cell. Such a nerve fiber is a branch of a **MOTOR** neuron that extends outward from the brain or spinal cord. The site where the nerve fiber and muscle fiber meet is called a neuromuscular junction (myoneural junction). At this junction the muscle fiber membrane is specialized to form a motor end plate. The end of the motor nerve fiber is branched, and the ends of these branches project into recesses (synaptic clefts) of the muscle fiber membrane. The cytoplasm at the ends of the nerve fibers is rich in **MITOCHONDRIA** and contains many tiny (synaptic) vesicles that store chemicals called **NEUROTRANSMITTERS**. When a nerve impulse traveling from the brain or spinal cord reaches the end of a motor nerve fiber, some of the vesicles release neurotransmitter into the gap between the nerve and the motor end plate. This action stimulates the muscle fiber to contract. A muscle fiber contraction is a complex action involving a number of cell parts and chemical substances. The final result is a sliding movement within the myofibrils in which the filaments of actin and myosin merge. When this happens, the muscle fiber is shortened, and it pulls on its attachments. The length and tension of muscles vary indirectly. In the contraction mechanism, the chemical mechanism of action involves kinesins and dyneins, which are microtubule-dependent motor proteins that advance in incremental steps toward opposite ends of the microtubule cables. Both mechanochemical enzymes make use of a pair of motor domains that take intersecting hand-over-hand advances along the surface of the microtubule. In vitro measurements have provided proof that these head domains make steps of 8 nm and generate in the order of 6 pN of peak force during a single ATP hydrolysis cycle. Chemical advancement velocities are ATP dependent of single kinesin molecules obey the Michaelis–Menten relationship. Myosins are one- and two-headed actin-dependent chemical motors with step sizes ranging from 5 nm to greater than 40 nm. In particular, the two-headed isoform of Myosin II contribute in the contractile assemblies that manipulate the sarcomere length in muscle cells as well as influence the actomyosin ring constriction as part of the cytokinesis during cell division. Because the orientation of these actin filaments have inherently different polarity, myosins reverse polarity along the myosin filaments, and ATP hydrolysis cause the actin filaments to advance toward each other as an integral part of the motor domains. One-headed myosins do not have tails that form coiled coils, in contrast to Myosin I. One-headed myosins as a result do not actively participate in contractile mechanisms. Alternatively, the tails of these myosins facilitate the binding of vesicles and organelles and in this manner to transport them in lengthwise direction along actin filaments (see [Figure M.160](#)).

Figure M.160 Muscle fiber anatomical diagram. Muscle contraction based on the chemical attraction between actin and myosin fibers. (Courtesy Hank van Helvete.)

Muscle, major skeletal groups

[biomedical, chemical, electromagnetism, mechanics] The major SKELETAL MUSCLE groups are facial, mastication, head, pectoral girdle, arms, abdominal, pelvic, and legs. The anterior view of skeletal muscles within the HUMAN BODY shows the frontal muscle structure. The facial muscles are epicranii, orbicularis oculi, orbicularis oris, buccinator, zygomaticus, and platysma. The epicranii covers the upper part of the cranium and has two parts, one that lies over the frontal bone and another that lies over the occipital bone. Lifting the eyebrows and making the forehead wrinkle are its main functions. Multiple stimulations of these muscles can lead to headaches. The orbicularis oculi is a ring of muscle that surrounds the EYE and is used for closing or blinking of the EYE. It also aids in the FLOW of tears. The orbicularis oris orbits the mouth and is also known as the kissing muscle since it allows the mouth to pucker and help keeping food in place is done by the buccinator muscles. They also aid in blowing AIR out of the mouth. Zygomaticus' main function is allowing the corner of the mouth to smile or laugh. The platysma extends from the chest to the neck and its function can be seen by the expression of pouting. Chewing movements are accomplished by four pairs of muscles that are part of mastication. These muscle pairs are masseter, temporalis, medial pterygoid, and lateral pterygoid. Two of these pairs close the mouth while the others allow for side-to-side movements. The masseter is primarily for raising the jaw. A fan-shaped muscle used also for raising the jaw is known as the temporalis. The medial pterygoid is used for closing the jaw and allowing for the sliding movements. The lateral pterygoid allows the jaw to close and move forward. There are four pairs of muscles that move the head, allowing for rotation. The sternocleidomastoid is located in the side of the neck and when one side contracts, the head is turned to the opposite side. When both are contracted, the head is bent toward the chest. In the back of the neck, the splenius capitis allows the head to rotate and bend toward one side. For rotating, extending, and bending the head, the semispinalis capitis and longissimus capitis both help with these functions. Muscles that move the pectoral girdle or chest area include the trapezius, rhomboideus major, levator scapulae, serratus anterior, and pectoralis minor. The trapezius muscle raises the shoulders allowing for the "shrugging" expression. The rhomboideus major connects the upper thoracic vertebrae to the scapula and helps to raise the scapula. The levator scapulae runs almost vertical along the neck also helping to raise the scapula. Moving the scapula downward is accomplished with the serratus anterior. It also moves the shoulders forward when pushing something. The pectoralis minor lies beneath the pectoralis major and can move the ribs. For the upper arm, the muscles can be grouped by their primary actions of flexors, extensors, abductors, and rotators. The flexors are the coracobrachialis and pectoralis major, which flex the arm and move the arm across the chest. The extensors are the teres major and the latissimus dorsi that allow for rotation and moving the shoulder down and back. The supraspinatus and deltoid both help in abduction in the upper arm. The subscapularis, infraspinatus, and teres minor allow for rotation medially and laterally. In the forearm there are seven major muscles and can be categorized by their action. The flexor muscles are the biceps brachii, brachialis, and the brachioradialis all of which help in the rotation and lateral movements about the elbow. The primary extensor of the elbow is the triceps brachii. To rotate the arm, the supinator, pronator teres, and pronator quadratus allow for movements. In the wrist, hand, and fingers, the two major groups are flexors and extensors. Flexing of the wrist is accomplished with the assistance of the flexor carpi radialis and the flexor carpi ulnaris. The palmaris longus connects the humerus to the palm and functions to flex the wrist. To make a fist the flexor digitorum profundus flexes the distal JOINTS of the fingers. All four of these are flexors. The extensors of the wrist and hand are the extensor carpi radialis longus, extensor carpi radialis brevis, extensor carpi ulnaris, and the extensor digitorum. The first three aid in extending the wrist while the last one deals with the functions of the fingers. Four muscles located in the abdominal WALL region help with breathing, defecation, urination, and childbirth. These muscles are the external oblique, internal oblique, transversus abdominis, and the rectus abdominis. All of these muscles function in a similar manner and compress the abdominal cavity. The pelvis region consists of two major muscle sheets that are the pelvic diaphragm and the urogenital diaphragm. The pelvic diaphragm has two major muscles that are the levator ani and the coccygeus that provide a sphincter-like action in the anal canal and the vagina in women. The three major muscles within the urogenital diaphragm are the superficial transversus perinei, bulbospongiosus, and the ischiocavernosus muscles. The superficial transversus perinei supports the pelvis. The other two help in urination within men

and constriction of the vagina from opening in women. In the thigh, there are two groups: the anterior and posterior groups. The anterior groups' main job is for flexing while the posterior groups are for extending or rotation. The psoas major and the iliacus make up the anterior group and their function is to flex the thighs. The posterior group consists of the gluteus maximus, gluteus medius, gluteus minimus, and the TENSOR fasciae latae. These muscles help in flexing and rotating the thigh. A third group of muscles, the adductor longus, adductor magnus, and gracilis, adduct, flexes and/or rotates the thigh. The muscles of the LEG can be separated into two categories that are the flexors and extensors about the knee. The flexors are the biceps femoris, semitendinosus, semimembranosus, and sartorius and all help to flex and rotate the leg. The extensors of the lower legs are the quadriceps femoris, which extends the leg at the knee. In the ankles, feet, and toes, there are four categories of muscles based on their function. The dorsal flexors, which include the tibialis anterior, peroneus tertius, and extensor digitorum longus aid in the moving the foot upward. The plantar flexors move the foot downward and contain the GASTROCNEMIUS, soleus, and flexor digitorum longus muscles. Turning the sole of the foot outward or inward is accomplished by the two groups: the invertor and evertor. The tibialis posterior is within the invertor group and allows for the INVERSION of the foot. The eversion of the foot is done by the peroneus longus that is within the evertor group. Although each muscle is specialized within a certain area, all of these muscles help in maintaining posture and movement (see Figure M.161).

Figure M.161 Diagram of lever classes, with respective locations of movement force, resistance, and axis of rotation defining the individual classes. (Continued)

Figure M.161 (Continued) Diagram of lever classes, with respective locations of movement force, resistance, and axis of rotation defining the individual classes.

Muscle, performance

[biomedical, chemical, electromagnetism, mechanics] The following factors affecting SKELETAL MUSCLE strength and performance can be identified. Gender, AGE, training experience, muscle strength, and fatigue all affect strength performance. Muscles in humans makes up 40%–43% of the total body weight in men on world-wide average; and respectively, 23%–25% statistically averaged in women. For a healthy, average height woman who weighs 62 kg, 7 kg is composed of bones, 16 kg of organs and SKIN, 16 kg of fat, and 23 kg of muscles. Both male and female can develop muscular strength at the same rate, although due to hormones, namely testosterone, male muscles have a greater potential for strength. As humans mature, strength increases. However, roughly by age 30 (depending on a broad range of boundary conditions, including training and consumption of food, as well as natural and artificial chemicals), muscles start to degenerate. The degeneration is a reversible process but continuous training is required. The length of time devoted to training and the type of training regiment influence muscle strength. The initial length of the muscle fibers and the insertion length affect the amount that muscles can LIFT and support. Fatigue relates to the condition that the muscle does not allow for the same amount of power output. FATIGUE is highly variable and is influenced by the intensity and duration of the contractile ACTIVITY, by whether the muscle fiber is using aerobic or anaerobic METABOLISM, by the composition of the muscle, and by the fitness level of the individual. Most experimental evidence suggests that muscle fatigue arises from excitation–contraction

failure of control neurons and neuromuscular transmission. The ability for muscle to change its length or lengthwise tension has been shown by the process of contraction. The underlying factor is the exchange of energy from the BLOOD stream with the muscle cells (see [Figure M.162](#)).

Figure M.162 Diagram of energy exchange with muscle cells to support function. In addition, the production of waste during muscle action is illustrated, eluding the potential build-up of lactic acid, generating muscle fatigue and cramp. The build-up of lactic acid degrades the natural metabolic activities.

Muscle physics, skeletal muscles

M

[biomedical, chemical, electromagnetism, mechanics] A **LEVER** is a simple mechanical machine consisting of a bar on a fixed point that transmits a force. Lever types are defined by three classes according to the axis of rotation, resistive force, and movement force. In a third-class lever, the movement force is applied between the axis of rotation and the resistive force. This lever favors movement speed over movement force. Most muscles in the **HUMAN BODY** use this type of lever. A second-class lever is one in which the **RESISTANCE** is between the movement of force and the axis of rotation. This type allows for great movement force. When the axis of rotation is between the movement force and the resistance this lever is known as a first-class lever. They are like third-class levers since they are big on movement speed and lack in movement force. The bicep **MUSCLE** works as a third-class lever where the movement of force is between the axis of rotation and the resistance. The mathematical relationship of the force can be calculated upon knowing some muscle measurements. People are built differently and depending on their muscle force, force lever, or resistance lever to maintain balance and perform functions. Torque is the force that tends to rotate and turn things. Mathematically, it is equal to the force multiplied by the **DISTANCE**. This distance is usually radial from a central point. Power is the measure of how fast work can be done. It equals the amount of torque on an object multiplied by the rotational speed. To solve power as a function of human output, the following question can be proposed: How much power can a human output? One way to solve this problem is to see how fast one can run up a flight of stairs. First, measure the height of a set of stairs that reaches three stories. Second, record the time to run up the stairs. Finally, divide the height of the stairs by the time, where this equals the instantaneous speed. The weight of the individual must also be known. For instance, if it took 15 s to run up 10 m, then the speed equals 0.66 m/s (only speed in vertical direction is important). Then one needs to figure out how much force was exerted over 10 m, this force is equal to your weight. The amount of power output = weight multiplied by speed. $\text{Power}(W) = [\text{height of stairs(m)}/\text{Time to climb(s)}] * \text{weight}$ (Units: Newton [N]). The contractile strength of a muscle is most closely related to its cross-sectional size. The electrical **ACTIVITY** in muscle is due to the effect of the concentration gradients, the difference in potential across the membrane, and the **ACTIVE TRANSPORT** system. Positive and negative charged ions within the muscle fiber have the ability to move between intercellular fluids. These charges create a differential in potential. The net effect of these charges is a **POSITIVE CHARGE** on the exterior of the **MEMBRANE** and a negative

charge on the interior. In a healthy neuromuscular system, this polarized muscle fiber remains in equilibrium until upset by an external or internal stimulus. There are different measurement techniques to measure the mechanical and electrical properties of muscle. A dynamometer measures the mechanical force or power a muscle can exert and electromyography measures the electrical activity related to muscle contractions. Dynamometers measure mechanical power and come in a variety of different configurations. One such configuration allows measurement of the clench action of hands. The basis of surface myoelectric activity is the relationship between the ACTION POTENTIAL of muscle fibers and the extracellular recording of those action potentials at the SKIN surface. Electrodes, external to the muscle fiber can be used to detect action potentials. The most common electrodes are surface and fine wire electrodes. For general muscle groups surface electrodes are suitable, however, they are limited in detecting small muscles or muscles deep within the body, where fine wire electrodes are recommended. Detection electrodes are usually used in a bipolar manner. Two electrodes are positioned on the muscles while a third is a reference (GROUND) to the body. A difference preamplifier increases the AMPLITUDE of the signals between each of the detecting electrodes and the common mode reference. Signals nearly zero are deemed common mode signals. The difference preamplifier improves the signal-to-noise ratio allowing the SIGNAL of small twitch to be detected. The most common NOISE problem is 60 Hz interference. This signal distortion occurs when the reference ELECTRODE is not applied properly, a loose wire, or when electrical fields persist (see [Figure M.163](#)).

Figure M.163 Binary response of muscle contraction to electrical stimulus pulse trains.

Muscle relaxation

[biomedical] After DEPOLARIZATION the MEMBRANE of the muscle CELL repolarized, at which time the chemical “heads” on both the ACTIN and the MYOSIN of the sarcomeres are losing their attraction, allowing recoil to extend the muscle cell to expand.

Muscles, functioning

[biomedical, chemical, electromagnetism, mechanics] The length and tension of muscles vary indirectly. When a muscle contracts because of a LOAD applying a force, the MUSCLE produces one of two types of contraction: ISOTONIC or ISOMETRIC. Skeletal muscle contracts either by increasing or decreasing force while maintaining the same length (isometric) or shorten through constant force (isotonic). *Note:* Muscles generally have an ANTAGONIST or external phenomenon that increases the length of the muscle. Antagonists are for instance biceps and triceps in the human upper arm, whereas in BLOOD vessels the stretch is achieved by the pressure associated with the blood flow. A SKELETAL MUSCLE fiber is a thin elongated cylinder with rounded ends and may extend the full length of the muscle. Beneath its sarcolemma (CELL MEMBRANE), the cytoplasm or sarcoplasm of the fiber contains many small, oval nuclei and MITOCHONDRIA. Within the

sarcoplasm are numerous threadlike myofibrils that lie parallel to one another. They play an important role in muscle contractions. The response to a single stimulation or ACTION POTENTIAL is called a twitch. A twitch contains three parts: a latent period, a contraction period, and a relaxation period. During the latent period, there is no change in length but the impulse travels along the sarcolemma and down the t-tubules to the sarcoplasmic reticulum. Calcium is released during this period, triggering the muscle to contract. The contraction period is when the tension in the muscle increases causing a swiveling action of the SARCOMERE components. The contraction following from the chemical attraction resulting from the electrical POLARIZATION of both the ACTIN and the MYOSIN can be described as a rate of bond-forming (number of bonds: n_b) process expressed as $dn_b/dt = k_f n_L n_R - k_r n_b$, where k_f is the forward rate constant, n_L the number of ligands involved, and k_r the reverse rate constant. GEORGE IRVINE BELL (1926–2000) defined the rate constant as $k_r = k_{r0} \exp[\gamma_b F / N_c k_B T]$, with F the applied contraction force, N_c the number of LIGAND complexes in the actin–myosin volume, $k_B = 1.3806488 \times 10^{-23} \text{ kgm}^2/\text{s}^2\text{K}$ the Boltzmann constant, γ_b the extension of the muscle defined as the DISTANCE between adjacent attractive molecules (the actin molecules grab sequential molecules on the myosin in each stage of the contraction), k_{r0} the unloaded reverse rate constant in the absence of applied forces, and T the muscle temperature (giving additional meaning to “warming-up”). The molecular ADHESION was defined by Bell as the force per unit chemical bond: $f_b = F/n_b = 0.7(k_B T/\gamma_b) \ln([L]/K_D^0)$, where K_D^0 is the dissociation rate for the unstressed bonds and $[L]$ the free ligand concentration. This ADHESION applied generally to all cellular molecular attractions. The muscle tension decreases during the relaxation period and returns to its original shape. The three components of the twitch and the different types of contraction are well defined. When an increase in frequency with which a muscle is stimulated increases, the strength of contraction also increases known as WAVE summation. This occurs by re-stimulation of muscle fibers while there is still muscle contraction ACTIVITY. With several stimulations in rapid succession, calcium levels in the sarcoplasm increase and produces more activity and a stronger contraction. When rapid stimulation occurs and there is not enough time between successive stimulations a buildup of calcium can occur and there will be no relaxation between stimulations. This leads to a smooth sustained contraction known as tetanus. There are three types of muscle in the HUMAN BODY: skeletal, smooth, and cardiac. Smooth muscles can be found lining organs in the body, and cardiac muscle pertains to the HEART. The movements of the bones at JOINTS and posture maintenance are the main job of skeletal muscle. Skeletal muscles mode of control is voluntary, meaning the user has control of its actions, while smooth and cardiac muscles are involuntary. Smooth muscle is controlled by the autonomic nervous system and is found primarily in the walls of organs and tubes. The spindle-shaped cells that make up the composition of this type of muscle are arranged in sheets. These cells contain small amounts of sarcoplasmic reticulum but lack transverse tubules. The cells are made up of thick and thin myofilaments but do not contain sarcomeres and therefore are not striated like skeletal muscles. Chemically, calcium binds to a protein and induces contraction. There are two types of smooth muscles: visceral and multiunit. Visceral is found in the digestive, urinary, and reproductive systems. For this type of smooth muscle, a unit is composed of multiple fibers that contract and in some cases are self-excitable. In multiunit smooth muscle, nervous stimulation activates motor units. This type is found lining the walls of large blood vessels and in the EYE. They also are located at the base of follicles and can produce a “goose-bump” effect. Cardiac muscles have a distinctly different configuration. Heart walls have three distinct layers, which are the endocardium, myocardium, and epicardium. The endocardium lines the CIRCULATORY SYSTEM, is the innermost layer, and is composed of epithelial tissue. The myocardium is the thickest layer and consists of cardiac muscles. The epicardium is a thin layer and is the external MEMBRANE around the heart. Cardiac muscle is striated and contains sarcomeres, which makes this muscle similar to skeletal. Adjacent cells are joined end-to-end at structures known as intercalated discs. These discs contain two types of junctions: desmosomes and gap junctions. Desmosomes act like rivets and hold cells tightly together while gap junctions allow action potentials to spread from one cell to another. The specific characteristic for the heart muscle is the intercalated discs with desmosomes and gap junctions. Cardiac muscle forms two functional units called the atria and ventricles. There are two of each where by the atrias both act together, followed by the ventricles. For contraction, there are two types of cells: contractile cells and autorhythmic cells. The contractile cells contract when stimulated while the autorhythmic cells are automatic. For focus of discussion of this topic, only skeletal muscle will be explored. Skeletal muscles have

the ability to shorten quickly and recover, where this action is defined as contraction. One end of the muscle, origin, is stationary while its other end, insertion, shifts. A contraction always moves from the insertion to the origin. When a contraction occurs, both the AGONIST muscle and ANTAGONIST muscle work against each other. The agonist muscle or flexion is the muscle that is being acted upon while the antagonist or extension muscle contracts in opposition to the flexion. A contraction is only the shortening of the muscle and does not describe the actual generation of a force. A force only occurs when there is a RESISTANCE to the muscle contraction. To understand the nature of contractions, the ANATOMY of skeletal muscle must be studied. Second, the PHYSIOLOGY of muscular contraction, meaning the excitation and relaxation will be investigated. The PHYSICS of the muscle acting as a lever for skeletal muscle is one ENGINEERING point that shows the impact of the attachment to the bone to provide the level, comparing human arms to that of apes and monkeys. Muscle is composed of several kinds of tissue including striated cells, nerve, blood, and various connective tissues. The basic unit of contraction in an intact skeletal muscle is a motor unit, composed of a group of muscle fibers and a motor neuron that controls them. When the motor neuron fires an action potential, all muscle fibers in the motor unit contract. The number of muscle fibers in a motor unit varies, although all muscle fibers in a single motor unit are the same fiber type. Thus, there are fast-twitch motor units and slow-twitch motor units. The determination of which kind of fibers associated with a particular neuron appears to lie with the NEURON itself. Force of contraction within a skeletal muscle can increase by recruiting additional motor units where by this process is called motor unit recruitment. An individual muscle is separated from adjacent muscles and held into position by layers of fibrous connective tissue called fascia (a bundle). This fascia is part of a network of connective tissues that extends throughout the skeletal muscle system and its attachment with other parts. These connective tissues become either tendons or aponeuroses. The fibers in the tendon become intertwined with bone, which allows muscle to be connected with bone. Aponeuroses are broad fibrous sheets that may be attached to adjacent muscles. The layer that closely surrounds a skeletal muscle is called the epimysium. Other layers of connective tissue called the perimysium extend inward from the epimysium and separate the muscle tissue into small compartments. These compartments contain bundles of skeletal muscle fibers called fascicles. Each muscle fiber within a fascicle is surrounded by a layer of connective tissue in the form of a thin, delicate covering called endomysium. These layers allow for some independent movement as well as allowing blood vessels and nerves to pass through (see Figure M.164).

Figure M.164 Force displacement diagram of isometric (constant length) versus isotonic (constant force) muscle contraction, respectively, in response to stimulus from the motor neuron.

Musculoskeletal system

[biomedical, general, mechanics] Biological structure of **MUSCLE** attachment to bones of the skeleton in animals by means of connective tissues including cartilage, tendons, and ligaments. The muscle attachments provides the mechanism to apply a force, or more specifically, a torque which provides stability and the capacity to perform **MOTION**.

Musschenbroek, Pieter van (1692–1761)

[electrical, mathematics, mechanics] See **VAN MUSSCHENBROEK, PIETER**.

Mutual stable equilibrium

[thermodynamics] Subsystems of a composite system that is in a stable **EQUILIBRIUM STATE**, are in mutual stable equilibrium as well. Subsequently, when a composite system is in partial equilibrium the subsystems will be in partial mutual stable equilibrium.

mv (Product of mass and speed)

[general] The momentum (p_{motion}) of an object in **MOTION**: $p_{\text{motion}} = mv$, the momentum changes in response to an impulse (J). The impulse is defined as the summation of all forces (ΣF) applied over a period of time preceding the change in momentum, usually expressed as the integral over **TIME** (t) for the forces $J = \int_{t_1}^{t_2} F dt$.

Myelinated nerve

[biomedical, electronics] Nerve **CELL** with myelin envelop over a short **DISTANCE** at consecutive segments over the entire length of the nerve cell. Certain specialized nerve cells have formed a coalition with a separate cell to create a unique conduction system. Over time the axon is wrapped in patches of fatty, white myelin sheath at regular intervals along the length of the axon. The myelin is a secretion resulting from the **ACTIVITY** of specific cell type called glial cells. Oligodendrocytes produce myelin sheaths that insulate certain vertebrate axons in the central nervous system. Schwann cells have a similar function in the peripheral nervous system. Myelin builds up over time and is not fully formed at birth. The propagation speed for action potentials (conduction rate) of myelinated nerve cells is two orders of **MAGNITUDE** greater than that for unmyelinated nerve cells, switching from 2 m/s to 120 m/s (*also see* **NERVE**) (see [Figure M.165](#)).

Figure M.165 Outline of the myelinated nerve principles. Description of the action-potential propagation for a myelinated nerve axon.

Myopia

[biomedical, general, optics] Optical property of the **EYE** where far away objects cannot be displayed sharp or in focus on the **RETINA** due to anatomical disorder of the eyeball that place the **LENS** of the eye at a too

great-a-distance to the retina so that the accommodation process will no longer allow for adjustments to fully focus. The far-point of the myopic eye is relatively close, sometimes within meters, or CENTIMETERS instead of infinity. This condition can be corrected by a corrective, DIVERGING LENS, that places the object as a virtual image at a reduced DISTANCE (see Figure M.166).

Figure M.166 (a) Myopia and vision correction by means of a lens in front of the eye and (b) the effects of LASIK surgery to correct myopia on a more permanent basis.

Myosin

[biomedical, chemical] Chemical structure working with ACTIN to perform contraction in MUSCLE tissue (see MUSCLE).

Myotis pulse

[acoustics, biomedical, theoretical] Frequency sweep in acoustic scanning for the *Myotis* family of bats during hunting. This specific sweep spans one OCTAVE, for instance, from approximately 40–80 kHz over a specific time span. The time span between pulses generally ranges from 50 to 100 ms in cruising mode (scanning), whereas the pulse interval can decrease to 10–50 ms during attack for hunting mode. In comparison, the acoustic pulse of the *Eptesicus* bat is quite different. For the *Eptesicus* bat, both the sweep speed and the frequency range changes between surveillance mode and hunting mode. In hunting mode the FREQUENCY SPECTRUM is lower (i.e., shorter wavelength range with increased ASSOCIATED RESOLUTION) while simultaneously the pulse length is shorter. This type of SIGNAL PROCESSING is applied in other forms by several other animals. The same principles are applied both in communication as well as in diagnostic scanning applications in both biological and device imaging. For instance, the hawk applies a similar concept in VISION, switching from low resolution scanning to high-resolution hunting, using specifically different anatomic and functional regions of the RETINA, with respective signal processing on different sections of the brain. The device applications vary from mechanism of action to user interface with the operator (see BAT and ECHO-LOCATION) (see Figure M.167).

Figure M.167 (a) A bat and (b) the principle and application of the myotis pulse in bats for guidance and recognition of prey during hunting. (Courtesy of "Sarah" acquired during an award winning project with American Museum of Natural History: "The World Through a Bat's Ears"; <http://www.amnh.org/learn-teach/young-naturalist-awards/winning-essays2/2005-winning-essays/the-world-through-a-bat-s-ears>.)

η

[fluid dynamics] (Greek: “eta”), [coefficient of] Viscosity of a FLUID in motion, often confined to an incompressible, irrotational fluid. The ratio of shear stress to velocity gradient: $\eta = (F/A)/(dv_x/dz)$, where F is the force parallel to the surface (A) at which the VISCOSITY is determined, v_x the FLOW velocity and z the DISTANCE perpendicular to the flow. The generally accepted unit for viscosity is *poise* [P], named after the French physiologist JEAN LÉONARD MARIE POISEUILLE (1799–1869). Ten poise equal one Pascal second [Pa s]. The KINEMATIC VISCOSITY (ν_{kin}) is the viscosity per unit DENSITY (ρ): $\nu_{\text{kin}} = \eta/\rho$. The unit for kinematic viscosity is cm^2/s , which equals the unit *stokes*: $1St = 1 \text{ cm}^2/\text{s}$, after the Irish physicist and mathematician GEORGE GABRIEL STOKES (1819–1903) (see [Figure N.1](#)).

Figure N.1 Viscous flow of water from a roof after a rain storm.

N¹³, ¹³nitrogen

[atomic, biomedical] Radioactive isotope of ¹⁴nitrogen (¹³N), which decays to carbon-13 (¹³C) by beta + DECAY (e^+) with a half-life of 9.965 min: $^{13}\text{N} \rightarrow ^{13}\text{C} + e^+ + \nu_e + 1.20 \text{ MeV}$, where e^+ is a positron and ν_e and electron NEUTRINO. N¹³ is used in positron emission TOMOGRAPHY imaging. N¹³ is produced by bombarding oxygen by hydrogen (i.e., PROTON) with kinetic ENERGY of slightly more than 5.55 MeV: $\text{O}^{16} + \text{H}^1 \rightarrow \text{N}^{13} + \text{He}^4$.

N¹⁴, ¹⁴nitrogen

[atomic, biomedical] Standard nitrogen: ¹⁴N, discovered by the Scottish physician, chemist, and botanist Daniel Rutherford (1749–1819) in 1772. The Earth’s ATMOSPHERE consists of approximately 78% nitrogen as a GAS under standard conditions. Nitrogen has a EVAPORATION temperature (boiling point) at 77.355 K = −195.795°C and a SOLIDIFICATION temperature (MELTING POINT) of 63.15 K = −210.00°C; the TRIPLE POINT is at 63.151 K under pressure of 12.52 kPa, and the critical point is at 126.192 K at

3.3958 MPa. The heat of FUSION for nitrogen is 0.72 kJ/mol and the heat of vaporization for nitrogen is 5.56 kJ/mol. Nitrogen is a popular and effective component of fertilizer. ANTOINE-LAURENT DE LAVOISIER (1743–1794) named nitrogen “mephitic air” referring to the fact that animals would not survive and flames were extinguished when under the inert 100% concentration, a name that is found to carry through in several languages. Evaporating LIQUID nitrogen provides low-rolling clouds of nitrogen and condensate water vapor (see Figure N.2).

(a)

(b)

Figure N.2 (a) Nitrogen in dewar used for refrigeration of samples in test-tubes. (b) Illustration of the atmospheric nitrogen cycle.

Nabla (∇)

[computational, fluid dynamics, mechanics] Differential operator describing the mathematical operator for expressing gradient, DIVERGENCE, or curl. In mathematical expression, the application to a function (f) is ∇f , pronounced as “del f ,” where $\nabla f(x, y, z) = (df/dx, df/dy, df/dz)$; as a Cartesian gradient, this yields $\nabla f(x, y, z) = (df/dx) + (df/dy) + (df/dz)$. As an expression for divergence, the formulation is in “dot” product: $\nabla \cdot f(x, y, z) = \text{div } \mathbf{f}(x, y, z) = (du/dx) + (dv/dy) + (dw/dz)$, where the matrix function $\mathbf{f}(x, y, z) = u\vec{i} + v\vec{j} + w\vec{k}$ with $\vec{i}, \vec{j}, \vec{k}$ the unity directional vectors for the x , y , and z directions, respectively. The curl is a vector operator describing the rotation in infinitesimal steps of a three-dimensional vector field: $(\nabla \times \mathbf{f}) \cdot \vec{n}$, where $\vec{n}$ is the normal vector.

National Advisory Committee for Aeronautics (NACA)

[general] A US federal agency erected in 1915 with the goal to institutionalize aeronautical research as well as to promote and undertake aeronautical activities and exploration. The agency was dissolved in 1958. The assets and its personnel were transferred to the newly created NATIONAL AERONAUTICS AND SPACE ADMINISTRATION (NASA).

National Aeronautics and Space Administration (NASA)

[general] A US agency founded in 1958 under President Dwight David “Ike” Eisenhower (1890–1969; 34th president); it is responsible for aeronautics and aerospace research and the US national civilian space program. Many exploratory rockets and manned space flights have been planned and executed by NASA, following the work initiated by the NACA in 1946 with the launch of the Bell X-1 for exploration of supersonic flight and the early 1950s launch of an artificial SATELLITE following the space journey by Sputnik-1 in 1957 launched by the Union of Soviet Socialist Republics (USSR [Russian: Союз Советских Социалистических Республик: СССР]) (see [Figure N.3](#)).

(b)

Figure N.3 (Continued) (b) NASA space flight emblem.

National Center for Biotechnology Information (NCBI)

[biomedical] A US government-funded national resource for molecular biology information founded in 1988. The NCBI is a subdivision of the US National Library of Medicine (NLM). The NLM is a branch of the US National Institutes of Health.

National Institute of Standards and Technology (NIST)

[general] NIST is the US federal technology agency instituted in 1988; its intention is to work with the industry to develop and apply technology, measurements, and standards. NIST has, for instance, advanced the development of prototype tools for experimental medical imaging techniques for diagnostics of medical conditions. Between 1901 and 1988, it was known as the National Bureau of Standards.

National Institutes of Health (NIH)

[biomedical] An agency of the US Department of Health and Human Services. The primary agency of the US government responsible for all health-related and biomedical research (see [Figure N.4](#)).

Figure N.4 Illustration of the NIH emblem.

[biomedical] The US medical library founded in 1836 and is the largest medical library in the world. The NLM also supports and conducts research. Additionally, the NLM support the development and training in biomedical informatics and health information technology.

Natural angular frequency

[acoustics, general] Resonant frequency of an undamped, unforced OSCILLATOR: $\omega_0 = \sqrt{(k_{\text{spring}}/m)}$, where k_{spring} is the spring-constant for the flexible medium and m the mass of the resonator in MOTION with respect to the flexible medium (i.e., spring). In case the RESONANCE is dampened by a “pod” with dampening coefficient b_{damp} , the frequency for the DRIVEN DAMPED HARMONIC OSCILLATOR becomes the resonant angular frequency: $\omega_{\text{Res}} = \sqrt{(\omega_0^2 - (b_{\text{damp}}^2/2m^2))}$. The NATURAL FREQUENCY (ν_0) associated with the angular frequency ($\nu_0 = \omega_0/2\pi$) is also referred to as the “resonant frequency” (see Figure N.5).

Figure N.5 (a) Metronome, used for setting the pace during a musical performance.

(Continued)

(b)

Figure N.5 (Continued) (b) The pendulum is maintained by gears that rotate under the influence of weights.

Natural convection

[general] Fluid motion as well as HEAT TRANSFER based on thermal gradient; no active mechanism is involved. For instance, BUOYANCY forces driving the FLUID motion due to difference in density resulting from temperature gradients and variations in the fluid, for example, “warm air rise” (*also see CONVECTION*) (see [Figure N.6](#)).

Figure N.6 Natural convection of rising warm air and the ensuing wind generated based on the thermal gradient induced by the differences in specific heat (related terminology: heat capacity or thermal capacity) of land and water masses and the resulting solar heating during the day versus radiant cooling at night.

Natural frequency

[acoustics, electromagnetism, general, mechanics] Resonant phenomena of mechanical devices and electronic circuits based on their composition characteristics (*also see* **HELMHOLTZ RESONATOR**). The natural frequency (ν_0) of a single-opening design (e.g., GLASS bottle; a SOUND is generated when blowing over the open neck of the bottle) is mathematically defined by the physical characteristics including device volume V , cross-sectional area of the ORIFICE A , effective neck length, which includes a correction for the air-volume near the opening (i.e., $\delta\ell$) that flows in and out in order to generate the sound $\ell' = \ell + \delta\ell$, yielding $\nu_0 = v_s / 2\pi\sqrt{A/\ell'V}$, or $\omega(\vec{r}, t) = A\sqrt{E_{\text{mech}}/\rho\ell'^2}$, with v_s the speed of sound, E_{mech} the Young's modules, and A is the constant. The HELMHOLTZ RESONATOR has a behavior similar to a mass-spring harmonic oscillator with mass $m = \rho A\ell'$ and spring-dashpot ELEMENT where for a volume of FLUID, the spring constant is defined by $k = \rho v_s^2 (A^2/V)$. The dampener or DASHPOT will contribute a RESISTANCE R to the ENERGY equation (resulting in extinguishing the AMPLITUDE); however, generally the resonant frequency is in this case defined as $\nu_0 = 1/2\pi\sqrt{k/m}$. Analogously, the RESONANCE FREQUENCY for an electronic circuit with a RESISTOR (R), CAPACITOR (C), and INDUCTOR (L) in series is given as $\nu_0 = 1/2\pi\sqrt{1/LC}$, where the resistor will merely reduce the amplitude as a function of time (see [Figure N.7](#)).

Figure N.7 Tuning fork that will resonate at the natural frequency defined by the metal and geometrical configuration.

Natural light

[general] See SUN LIGHT.

Natural logarithm

[general] Logarithm to the base e , where $e \cong 2.718281828$, written as $\ln x$ or $\log_e x$, where $\ln a = \int_1^a (1/x)dx$, also known as “hyperbolic logarithm.” The concept of the natural logarithm was documented back to 1619 in tabulated solutions by John Speidell (~1600 to ~1635?), but was officially mentioned in 1668, by the German scientist and land surveyor Nicholas (Nikolaus) Mercator (1620–1687) in his work *Logarithmotechnia* (*also see* **LOGARITHM**).

Natural materials

[biomedical] Materials that are biocompatible with the biological nature, can be integrated in biological units (e.g., prosthetic devices and PACEMAKER), or can degrade without release of toxic components (e.g., SCAFFOLD for tissue ENGINEERING and regenerative medicine).

Navier, Claude-Louis Marie Henri (1785–1836)

[computational, fluid dynamics, general] An engineer and scientist from France. Known for his FLUID DYNAMICS work, specifically describing the equation of MOTION behavior of an INCOMPRESSIBLE FLUID (the NAVIER–STOKES EQUATION) and the follow-up by SIR GEORGE GABRIEL STOKES (1819–1903), and in MECHANICS defining the general theory of ELASTICITY in a convenient mathematical form in 1821. In 1826, Claude Navier defined the ELASTIC MODULUS as a material property (see [Figure N.8](#)).

Figure N.8 Claude-Louis Marie Henri Navier (1785–1836): bust erected at the École Nationale des Ponts et Chaussées in Paris, France.

Navier–Stokes equation, viscous fluid

[energy, fluid dynamics, general] Equation of MOTION, specifically for FLUID behavior, defined by the work of CLAUDE-LOUIS NAVIER (1785–1836) in 1822, and later refined by SIR GEORGE GABRIEL STOKES (1819–1903). The following definitions are used in the description of the Navier–Stokes equations for FLOW: the three-dimensional flow velocity is defined by $\vec{u} = (u, v, w)$, Cartesian coordinate system $\vec{x} = (x, y, z)$, ∇ is the Laplace operator, P the pressure, Q resp. q the heat flux, $\vec{g} = (g_x, g_y, g_z)$ gravitational orientation with respect to flow ELEMENT, E_t the total ENERGY of the system, Pr is the Prandtl number, Re is the REYNOLDS NUMBER, ρ is the density of the fluid,

$$\tau = \begin{pmatrix} \sigma_{xx} & \tau_{xy} & \tau_{xz} \\ \tau_{yx} & \sigma_{yy} & \tau_{yz} \\ \tau_{zx} & \tau_{zy} & \sigma_{zz} \end{pmatrix}$$

defines shear stress, with σ the normal stress: for example, $\sigma_{xx} = (F_x/A_x)$, F_x the force ($\vec{F}$) acting in the x direction over a presumed contact surface: $A_x \mu$ the dynamic VISCOSITY, and λ the secondary

viscosity (which is zero for incompressible flow) The following Navier–Stokes equations are available to describe three-dimensional UNSTEADY FLOW phenomena. The EQUATION OF CONTINUITY reads $\partial\rho/\partial t + \partial(\rho u)/\partial x + \partial(\rho v)/\partial y + \partial(\rho z)/\partial z = 0$. The momentum equations (in CARTESIAN COORDINATES) for incompressible fluids are as follows:

$$\begin{aligned} \rho g_x - \frac{\partial P}{\partial x} + \frac{\partial}{\partial x} \left[2\mu \frac{\partial u}{\partial x} + \lambda \nabla \cdot \vec{u} \right] + \frac{\partial}{\partial y} \left[\mu \left(\frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right) \right] + \frac{\partial}{\partial z} \left[\mu \left(\frac{\partial w}{\partial x} + \frac{\partial u}{\partial z} \right) \right] \\ = \rho \left[\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z} \right], \end{aligned}$$

respectively

$$\begin{aligned} \rho g_y - \frac{\partial P}{\partial y} + \frac{\partial}{\partial y} \left[2\mu \frac{\partial v}{\partial y} + \lambda \nabla \cdot \vec{u} \right] + \frac{\partial}{\partial x} \left[\mu \left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \right] + \frac{\partial}{\partial z} \left[\mu \left(\frac{\partial w}{\partial y} + \frac{\partial u}{\partial z} \right) \right] \\ = \rho \left[\frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} + w \frac{\partial v}{\partial z} \right], \end{aligned}$$

and

$$\begin{aligned} \rho g_z - \frac{\partial P}{\partial z} + \frac{\partial}{\partial z} \left[2\mu \frac{\partial w}{\partial z} + \lambda \nabla \cdot \vec{u} \right] + \frac{\partial}{\partial x} \left[\mu \left(\frac{\partial u}{\partial x} + \frac{\partial w}{\partial z} \right) \right] + \frac{\partial}{\partial y} \left[\mu \left(\frac{\partial w}{\partial y} + \frac{\partial u}{\partial z} \right) \right] \\ = \rho \left[\frac{\partial w}{\partial t} + u \frac{\partial w}{\partial x} + v \frac{\partial w}{\partial y} + w \frac{\partial w}{\partial z} \right]. \end{aligned}$$

The energy of the flow system is defined by

$$\begin{aligned} \partial(E_t)/\partial t + \partial(uE_t)/\partial x + \partial(vE_t)/\partial y + \partial(zE_t)/\partial z \\ = -\partial(uP)/\partial x - \partial(vP)/\partial y - \partial(zP)/\partial z. \end{aligned}$$

In the case of flow around a prolate spheroid, the unsteady Navier–Stokes equations for incompressible flow at a function of TIME (t) are written as $\nabla \cdot \vec{u} = 0$ and $\partial \vec{u}/\partial t + \vec{u} \cdot \nabla \vec{u} = -\nabla \vec{P} + (1/Re_\infty) \nabla^2 \vec{u}$, and Re_∞ the Reynolds number based on the freestream flow velocity u_∞ . A prolate spheroid is a spheroid that is narrower

in the direction of flow than perpendicular to the flow, with d the diameter of the spheroid in the direction of flow; in contrast to a “squashed” spheroid, which will be wider in the direction of flow. (see Figure N.9).

NDE

[acoustics, electromagnetism, general, mechanics] See NONDESTRUCTIVE EVALUATION. It is also known as “nondestructive testing in quality control”.

Near point

[general, optics] The closet point to the EYE that can be observed with optimal accommodation. For the average human this point changes with AGE and is generally takes as 25 cm for a healthy young eye. By the age of 40, the near point, where a person can read comfortably at closest DISTANCE, can be increased to 40 cm (see [Figure N.10](#)).

Figure N.10 Illustration of the near-point for vision requiring corrective lenses.

Nearest-neighbor interpolation

[acoustics, computational, general] The data point closest to the requested x value data point on the phenomenological basis for a function ($f(x)$) with outcome is used to estimate the matching $f(x) = y$ value for the desired value. Interpolation is the process used to determine the missing values of a function based on the known values. There are four approximation methods available: nearest-neighbor interpolation, linear interpolation, polynomial interpolation, and spline interpolation.

Nearfield acoustic holography

[acoustics] Principle of acoustical imaging using an array of detectors to reconstruct the exact source location of an acoustic perturbation resulting from incident sound waves with respect to an acoustic discontinuity in a medium. In the near-field approach, the MICROPHONE array is placed in relative close proximity to the SOUND source array. The near field is generally defined as less than two wavelengths DISTANCE pertaining to the highest frequency used by the source. Often, this can be accomplished by using the source material as the detector, as in piezoelectric devices. This mechanism is of general application in ULTRASONIC IMAGING, specifically three-dimensional imaging. The mechanism of action is limited by the following two selection criteria, which both put requirements on the source operations and frequency band: spatial RESOLUTION, the ability to separate two sound sources, and dynamic range, sound MAGNITUDE level differences in dB between real secondary sound sources and the immediate surrounding mathematical artifacts. The imaging process is based on the following three steps: (1) transform the acoustical pressure field by spatial FOURIER TRANSFORM from the spatial domain to the WAVE number domain, (2) use the Dirichlet Green function to analyze the backpropagation of the different waves to the new defined plane, and (3) apply inverse spatial fourier transform to convert the ACOUSTICS signal from the wave number domain to

the spatial domain. The imaging planes are restricted to an orientation that can only be parallel with the detection array (see Figure N.11).

Near-field scanning optical microscope (NSOM)

[optics] The NSOM utilizes the fact that observations are made from a **DISTANCE** to the object under investigation at less than, or in the order of the interrogating wavelength. The illumination of the sample is also provided by a source with dimensions less than the wavelength. In addition, the NSOM does not provide an instantaneous global view of a section of the sample under investigation; however, the object is probed (scanned) in the near-field of the sample surface, by moving the source and/or detector across the specimen in nanometer steps, hence the name. A total **IMAGE** is formed with **RESOLUTION** less than the Abbe limit, after a series of line scans is performed, and all the intensity arrays are combined. Even though the NSOM is a relatively new instrument (inception 1982, Dieter Wolfgang Pohl and W. Denk), the concept was described in letter exchanges between Edward Hutchinson Synge and Albert Einstein in 1928. NSOM is an optical microscope that provides high spatial resolution capabilities with light sources in the visible spectrum. There is no high demand on sample preparation or confinements on working environments with NSOM. Thus far, it has been shown that working within the near field generates high spatial frequency information. However, what is needed in an optical microscope is high spatial frequency information on a subwavelength scale. Most explanations of the diffraction **BARRIER** on spatial resolution capabilities, take in account just the diffraction of light as it propagates through a collection **LENS** of a far-field optical system. Light will interact with the edges of the circular **APERTURE** of the lens causing the deviation of light from its initial line of travel. However, it is not just the interaction of the light with the collection lens that limits the resolution, but there exist the effects of the light interacting with detail in the sample structure. In the initial developmental stages of NSOM, the proposition was made for an optical microscope in which light would pass through a subwavelength aperture in an **OPAQUE** screen, illuminating an object directly below the screen. The screen would be maintained at a constant **DISTANCE** of a few nanometers from the sample surface, placing the sample in the near field. The idea is that the transmitted radiation would remain collimated, as it interacts with the sample. Therefore, a subwavelength beam interacts with a small volume **ELEMENT** of the sample, and this light that interacts with the sample is collected by an objective. The sample is basically broken into small **PIXEL** areas. The subwavelength **LIGHT SOURCE** would be scanned over

each pixel area, generating a two-dimensional intensity image. There are two theoretical parameters that give the near-field scanning optical microscope the high spatial resolution capabilities. The first theoretical boundary condition is that the sample is maintained in the near field by keeping the sub wavelength aperture a constant height above the sample surface. The second condition is that the spot size of the light that interacts with the sample is confined to the dimensions of the sub wavelength aperture. The combined effect of these two parameters yields high spatial frequency information on the sub wavelength scale. General design of NSOM microscope is as follows. The near-field scanning optical microscope can take on many different forms, depending on the user's specific application. Typically, the near-field scanning optical microscope is constructed on top of an inverted microscope. The inverted microscope allows the user to target specific areas on the sample surface before any high-resolution imaging is performed. First, laser light is passed through a bandpass filter to remove any undesirable wavelengths. The bandpass filter is followed by some wave plates, which are used to control the POLARIZATION state of the laser light. The light is then coupled into a single mode optical fiber via a launcher. The end of this single mode optical fiber is heated and pulled or chemically etched to form a subwavelength aperture. The small near-field resolution is primarily due to the tapered fiber tip design. The very end of the single mode optical fiber, where the subwavelength aperture was fabricated, is mounted to an atomic force microscope (AFM). The AFM head will be discussed in more detail, but it is part of the mechanism that is used to maintain the subwavelength light source at a constant height above the sample surface. The light is transmitted through the subwavelength aperture and impinges upon the sample that is mounted to an XYZ piezoelectric translation stage. This XYZ translation stage is used to scan the nanoscopic light source over each pixel area described earlier. The light interacts with a small volume element of the sample, and then, it is collected by the inverted microscope's objective. The collected light is optically guided out of the inverted microscope where it is sent to a detector. The type of detector that is used at the output of the NSOM depends directly on the desired application in which the system is being used. The optical information from each pixel that is measured by the output detector is sent to a computer. The computer is used to construct a high-resolution image of the sample and to run the ELECTRONICS involved in scanning.

NSOM Tip

The NSOM tip is the most essential part of the imaging device and requires that great care is taken in its preparation. NSOM tips have taken on many different shapes, sizes, and material make up. Most of the earlier NSOM tips suffered low transmission of coupled light and poor reproducibility. However, the most widely used NSOM tip design was adopted from Bell Labs. In the early 1990s, Bell Labs proposed a tapered single-mode optical fiber with a reflective metal coating as a design for an NSOM tip. These NSOM tips that are made from optical fiber are fabricated in two different ways, heating and pulling or chemically etching the fiber. In heating and pulling the optical fiber, a commercial micropipette puller is used in the fabrication process. Essentially, a laser is used to heat the optical material, and the fiber is then pulled to a fine point. At the tip of this point, an APERTURE with a diameter on the order of 50–100 nm is formed. One can carefully control the heating and pulling parameters, making this method of fabrication highly reproducible. On the other hand, chemical etching utilizes a SOLUTION that consists of hydrofluoric ACID with an organic buffer layer on top to fabricate the optical fiber. One end of a single-mode optical fiber that has been stripped of its cladding is immersed into the etching solution, which consists of a buffer layer on top of hydrofluoric acid. A MENISCUS is formed in two different locations along the fiber, due to electrostatic interactions between the solution's components and the fiber. However, the etching process only occurs at the organic solvent/hydrofluoric acid interface. As the diameter of the immersed optical fiber in the HF decreases with time, the height of the meniscus formed at the solvent/HF interface decreases. Over a period of time, the etching process is terminated and a tip is formed. The conical shape of the tip can be adjusted by changing the organic SOLVENT that is used in the etching solution. Although there now is a sub-wavelength aperture formed at the end of the single-mode optical fiber, the fabrication process is not complete. There still exists the need to coat the NSOM tip with a reflective metal. The reason for this metallic coating is related to the mode-field structure that propagates through an optical fiber. The ability of a single-mode optical fiber to guide and confine one wavelength of light is directly related to the dimensions and material composition of the optical fiber. As the diameter of the single-mode optical fiber decreases in the tapered region, the ability of the fiber

to confine and guide the light is lost. Therefore, the light is no longer confined to just propagate out of the subwavelength aperture; it escapes out of the sides of the tapered region. High spatial RESOLUTION capabilities of the near-field scanning optical microscope depend strongly on the fact that the beam spot size is to be confined to the subwavelength aperture. The metallic coating applied to the tapered region is required to prevent the leakage of light. This metallic coating also attenuates the light before it can escape. The NSOM tip proposed by Bell Labs, although the most widely accepted, is prone to some inefficiency problems. One such problem has to do with the amount of light that can be transmitted through the subwavelength aperture. A large quantity of light is lost by tip design itself, or the REFLECTION of the light back up through the fiber from the tapered region. Therefore, only a small fraction of the initial coupled light from the source is transmitted through the aperture. This inefficiency tends to limit the applications of NSOM. Feedback mechanisms employed to maintain a constant tip and sample separation. In order to achieve high-resolution imaging capability, an NSOM must employ another specific feature. The NSOM tip needs to be maintained at a constant height of a few nanometers from the sample surface during scanning. There are various techniques that can be employed to maintain a constant DISTANCE between the tip and the sample surface. However, only two of these techniques have become widely adopted by NSOM designers. Shear force tip feedback and tapping-mode feedback have their foundations in atomic force microscopy. These are the most reliable two methods available to maintain a constant tip and sample separation. Both methods involve the mounting of the NSOM tip to a QUARTZ tuning fork and driving the fork/tip system at mechanical resonance. However, one technique dithers the NSOM tip laterally in reference to the sample surface and the other dithers the tip perpendicularly.

Shear-force-mode tip feedback

The tuning fork uses shear-force tip feedback method, where the tip is dithered laterally in reference to the sample surface. An NSOM tip is rigidly attached to one arm of a quartz tuning fork that has a well-defined RESONANCE FREQUENCY of 32.768 kHz and a QUALITY FACTOR, Q , of around 7500 in AIR. Typically, the tip is mounted to the QUARTZ tuning fork using some sort of glue or epoxy. This fork/tip system has a new resonance frequency that is slightly lower than that of the quartz tuning fork, and a quality factor, Q , that ranges from 150 to 300. The fork/tip system is driven at mechanical resonance either by directly applying a sinusoidal voltage to the fork or by applying a sinusoidal voltage to a piezoelectric tube that shakes the fork/tip system at resonance. However, we will only discuss the situation in which the fork/tip system is mounted to a piezoelectric tube that shakes the fork/tip system at mechanical resonance. The quartz tuning fork is piezoelectric in nature. Therefore, the shaking of the fork/tip system at mechanical resonance induces a periodic voltage across the tuning fork that can be monitored through contacts integrated in each arm of the fork. As the resonating fork/tip system approaches the sample surface within a few nanometers, the NSOM tip experiences frictional forces. These frictional forces cause the fork/tip system to become damped, and the amount of DAMPING can be measured through the integrated contacts in each arm of the fork. Essentially, this resonating fork/tip system can be used as a mechanical pick-up for the frictional forces that cause damping. This measured voltage across the quartz tuning fork can be used in a closed loop feedback mechanism, which employs a lock-in amplifier and proportional integral (P.I.) electronic circuit, to maintain the NSOM tip at a constant DISTANCE from the sample surface. As the fork/tip system is brought close to the sample surface, frictional forces interacting with the NSOM tip causes the monitored potential across the fork to decrease in AMPLITUDE and shift in PHASE, any shift from 90° out of phase with the reference, generates an output voltage from the lock-in. An active feedback voltage is sent from the lock-in to the P.I circuit. The P.I circuit sends an immediate response voltage to the XYZ piezoelectric translation stage to adjust the z -position of the stage, in order to maintain the monitored potential at resonance.

Tapping-mode tip feedback: Tapping-mode feedback has also been employed to maintain the NSOM tip at a constant height above the sample surface. It is a more sensitive mechanical pick-up for the frictional forces that interact with the NSOM tip. However, the bend in the tip reduces the throughput efficiency. Therefore, in certain applications that require a relatively high intensity to interact with the sample, shear-force tip feedback will be chosen over tapping-mode feedback. The fork/tip system and the piezoelectric tube form the AFM head that was mentioned earlier in the shear-force mechanism. Essentially, an atomic force MICROSCOPE has been integrated into the NSOM. The atomic force microscope consists of the lock-in

amplifier, P.I circuit, and xyz piezoelectric stage, which are employed in a closed-loop feedback mechanism. As the tip is being scanned across the sample, that has some surface variations, the z-position of the piezo-electric stage is adjusted to maintain the monitored potential across the fork at resonance. A topography IMAGE can be formed serially, pixel by pixel, by monitoring z-voltage that has to be applied to the positioning stage. The beauty of having the atomic force microscope integrated into the NSOM is that intensity and topography images can be built simultaneously.

Intensity imaging

Most biological samples that are studied are very thin and transparent. There are not a great deal of contrast mechanism within the sample to exploit. Therefore, samples have to be treated with dyes, even in NSOM imaging. Typically, samples are stained with dyes that have specific ABSORPTION SPECTRUM. The stained samples are deposited on a piece of mica or a MICROSCOPE cover slip, and air-dried. A sample is mounted to the xyz piezoelectric stage, which scans the sample under the fixed NSOM tip. The light excites fluorescence in the sample is collected by the collection LENS of the inverted microscope. The collected light is optically guided out of the inverted microscope and is passed through a notch filter. The notch filter is used to separate the FLUORESCENCE from any laser light that may be propagating through the system. The light is sent to a high quantum efficiency detector, such as an avalanche photo DIODE operating in single PHOTON count mode. The detector measures the frequency at which photons strike the sensing ELEMENT in the detector.

Phase imaging

Additional work is being done to extend the capabilities of NSOM to include phase imaging. In order to achieve high-resolution subwavelength phase-contrast images an NSOM is integrated into an INTERFEROMETER. The ability to construct high-resolution phase images would have a huge impact in the study of biological samples. Samples would no longer need to be treated with dyes to have a contrast mechanism to exploit. This method would be one step closer to providing a system that could be used to IMAGE living cells. Since NSOM makes use of an optical fiber to achieve subwavelength RESOLUTION capabilities, a hybrid Mach–Zehnder interferometer utilizing an all fiber bidirectional coupler represents the system of choice. The Mach–Zehnder interferometer relies on the same phase sensitive information as described for the other interferometers. Only this time the recombination takes place after transmission instead of REFLECTION. (see [Figure N.12](#)).

Negative acceleration

[general] Acceleration in direction opposite to the direction of MOTION, resulting in a reduction in velocity, for example, applying the brakes.

Negative charge

[general] Charge consisting of a collection of electrons.

Negative kinetic energy

[nuclear, quantum] In QUANTUM MECHANICS, negative kinetic energy is a SOLUTION to the SCHRÖDINGER EQUATION involving QUANTUM TUNNELING. In general, there is no real negative kinetic energy. In the process of TUNNELING the momentum (classical mechanic, nonrelativistic: $p = mv$, where v is the velocity of mass m ; however, in quantum MECHANICS, the value is a solution to the Schrödinger equation) will have an imaginary value as well as an imaginary WAVE number, and hence “virtual” negative kinetic energy (since by definition $KE = p^2/2m$).

Negative lenses

[general] Lens with at least one concave surface, and hence a virtual FOCAL POINT and is diverging (see LENS).

Negative magnification

[general] Reduction in IMAGE size with respect to object (see MAGNIFICATION).

Negative temperature

[quantum, thermodynamics] Situation where electrons in a very low ENERGY state at micro Kelvin temperature that are virtually not able to move due to the fact that the POTENTIAL WELL is deep and narrow, which is inverted to a potential crest by manipulating the LATTICE. The crest is very stable and the energy cannot go down, and is hence considered “negative.” This concept of temperature is directly linked to the entropy of the system in a QUANTUM STATE, not anymore to the MOTION as in classical MECHANICS.

Nephelometer

[biomedical, fluid dynamics, geophysics, thermodynamics] The stationary or portable analytical instrument that can be applied to measure and analyze the light-scattering coefficient of atmospheric and laboratory aerosols to determine the concentration of suspended particulates in a LIQUID or GAS colloid. The nephelometer specifically gauges the stray light outside the path of incidence, hence determining the scattering CROSS SECTION. Specific applications are in drug solubility screening, and other general nephelometric measurements. The biomedical use relates specifically to immunological assay analysis, the principles of nephelometry rely on the reactions between antibodies and antigens. Antibodies in this realm are specific proteins of the immune system, whereas the antigens are the foreign proteins that can be a threat. Antibodies are very specific and selective in their association with particular antigens and will bind strongly to it (see [Figure N.17](#)).

Figure N.17 (a) Outline of Nephelometer, this one in particular operating at 550 nm. (Courtesy of Lynn Russell, Princeton University, Princeton, NJ.) (b) Professional Sensidyne Nephelometer. (Image courtesy of Sensidyne, LP—www.Sensidyne.com.)

Neptunium ($^{237}_{93}\text{Np}$)

[atomic, nuclear] Metallic ELEMENT discovered in 1940. The first ISOTOPE was produced in the University of California, Berkeley by Edwin Mattison McMillian (1907–1991) and Philip Hauge Abelson (1913–2004) by bombarding uranium with slow moving neutrons, creating neptunium-239, with a half-life of approximately 2.3–2.4 days, decays to plutonium-239 by beta DECAY. The most stable configuration is neptunium-237, discovered in 1942 by A. C. Wahl and Glenn T. Seaborg, has a half-life of 2,144,000 years, decays into protactinium-233 through ALPHA DECAY and is a by-product of the production of PLUTONIUM ($^{244}_{94}\text{Pu}$).

Nernst, Walther Hermann (1864–1941)

[biomedical, chemical, energy, thermodynamics] A German physicist and chemist who contributed to the model of the electrical stimulus propagation in biological communications, on a chemical (ionic) basis. Nernst was born in Wąbrzeźno, at the time Briesen part of the Prussian ("German") Empire now Poland. Walther Nernst is best known for his work in electrochemical applications in biology. More generally, the electrochemical efforts were focused on galvanic cells, such as the BATTERY. The galvanic NERNST POTENTIAL describes the electrical potential resulting from a CHEMICAL GRADIENT. The Nernst potential is the pivotal instrument in the HODGKIN–HUXLEY MODEL of propagation of electrical DEPOLARIZATION along the length of a nerve CELL. The electrical gradient across the cellular membrane is directly related to the VAN'T HOFF EQUATION or with respect to the OSMOTIC PRESSURE across a SEMIPERMEABLE MEMBRANE. Nernst received the Nobel Prize (1920) for his contributions to the chemical embodiment of the THIRD LAW OF THERMODYNAMICS applied to chemical affinity (see [Figure N.18](#)).

Figure N.18 Walther Hermann Nernst (1864–1941).

Nernst equation

[biomedical, chemical, thermodynamics] The electrical transmembrane potential resulting from a ION gradient expressed by Walter Nernst (1864–1941) as $\Delta V = \Delta V^\circ - (RT/nF_{\text{far}})\ln Q_r$, where $R = 8.3144621(75) \text{ J/Mmol}$ is the GAS constant, T is the (absolute) temperature, n is the number of transferred charges, Q_r is the reaction quotient, $F_{\text{far}} = 96485 \text{ C/mol}$ is the FARADAY CONSTANT, and ΔV° is the maximum POTENTIAL DIFFERENCE due to the MOTION of charges at normal conditions (temperature and pressure). The biological membrane potential was later defined more rigorously by the Goldman voltage equation.

Nernst potential

[biochemical, chemical, thermodynamics] See NERNST EQUATION.

Nernst principle

[thermodynamics] Theory of the electromotive force that defines the electrical potential of the voltaic CELL (i.e., BATTERY) developed by Walter Nernst (1864–1941) in 1888. The principle describes the change in free ENERGY from the chemical reaction that leads to the current produced. The GIBBS FREE ENERGY (G) is the energy that determines whether a reaction will be spontaneous or not. It is defined as the change in ENTHALPY (H) minus the TEMPERATURE (T) times the ENTROPY (S): $\Delta G = \Delta H - T\Delta S = \Delta U + P\Delta V - T\Delta S = \Delta G_0 + RT \ln Q_r$, where P is the pressure, U is the internal energy, V is the volume, $R = 8.3144621(75)$ J/Kmol is the GAS constant, and Q_r is the reaction quotient. Later this was summarized in the NERNST EQUATION.

Nernst–Planck diffusion equation

[biomedical, chemical, thermodynamics] The FLUX of ions across a membrane $\bar{J}_K$ [current/area] is calculated as a function of the concentration of the species of interest $[C_K]$, the DIFFUSION constant D_K : $\bar{J}_K = -D_K (\nabla[C_K] + ([C_K]/\alpha_K)\nabla V)$, where $\alpha_K = RT/F_{\text{far}}Z_K$ is the ION transfer rate, Z_K is the VALENCE of the ionic constituents in the diffusion process, $F_{\text{far}} = 96,485$ C/mol is the FARADAY CONSTANT, $R = 8.3144621(75)$ J/Kmol is the GAS constant, and T is the (absolute) temperature. It was described by WALTER NERNST (1864–1941) and ERNST PLANCK (1858–1947).

Neumann, Carl (Karl) Gottfried (1832–1925)

[computational, material] Scientist and mathematician from Prussia (now Germany). Neumann is best known for his pioneering work in the development of integral equations, as well as the NEUMANN SERIES. In 1875, Neumann also introduced the notation $\bar{d}$, representing an “inexact” differentiation associated predominantly with heat and work that depend on the path in which the differentiation is taken, later replaced by the symbol δ by James Riddick Parlington (1886–1965) in 1924, a chemist and thermodynamic physicist from Great Britain (*Note*: James Parlington worked under Walther Nernst [1864–1941]) (see [Figure N.19](#)).

Figure N.19 Carl (Karl) Gottfried Neumann (1832–1925).

Neumann boundary condition

[computational, thermodynamics] Specification of the derivatives of a function at a boundary of the vector domain, introduced by CARL NEUMANN (1832–1925). In thermodynamic applications, this defines the first order derivative conditions for the differential equation $f'' + f = 0$ over the interval $[x_1, x_2]$ as $f'(x_1) = \mathcal{A}_1$

and $f'(\mathbf{x}_2) = A_2$, where A_1 and A_2 are real numbers, or multidimensionally $\nabla^2 f + f = 0$, where ∇^2 is the Laplace operator, with on the boundary of the vector space $[\partial f(\vec{x})]/\partial \vec{n} = \varphi(\vec{x})$, with $\varphi(\vec{x})$ being a SCALAR function and $\vec{n}$ the normal to the boundary. In comparison, the Cauchy boundary condition is a combination of the Neumann boundary condition and the Dirichlet conditions and forms a mixed boundary condition.

Neumann function

[computational] Cylinder function of the second kind $N_p(x) = \lim_{k \rightarrow p} (J_k(x) \cos(k\pi) - J_{-k}(x)) / \sin(k\pi)$, where $J_k(x)$ and $J_{-k}(x)$ are BESSEL FUNCTIONS, named after CARL NEUMANN (1832–1925). The asymptotic value for large x yields $N_p(x) \approx \sqrt{2/\pi x} \sin(x - (p\pi/2) - (\pi/4))$. A special occasion is the radial equation, an specifically the Bessel equation of order ℓ yielding $\{ \rho^2(d^2/d\rho^2) + 2\rho(d/d\rho) + [\rho^2 - \ell(\ell+1)] \} f_\ell$, using $U_\ell(\rho) = \rho f_\ell(\rho)$. Solution to the Bessel equation of order ℓ (which is, for instance, an EIGENFUNCTION for the HYDROGEN ATOM $-(d^2/d\rho^2) + [\ell(\ell+1)/\rho^2] U_\ell(\rho) = U_\ell(\rho)$, with $U_\ell(\rho) = U_\ell(k\rho)$, k the wave-number), with Neumann solution: $N_p(x)$ (also see GREEN'S FUNCTION).

Neumann series

[computational] Analytical series developed by CARL NEUMANN (1832–1925) in 1877 defined as $\sum_{n=0}^{\infty} \mathbb{T}^n = (Id - \mathbb{T})^{-1}$, where $\mathbb{T}$ is an operator and Id and identity operator. Where the sum has analogies to the special case geometric series: $x/(1-x) = 1 + x + x^2 + \dots$. The identity operator, in the vector space X , defines the asymptotic behavior of the operator. The Neumann series has special implication for potential theory.

Neural network

[computational] Artificial network of information processing that is mirrored after how the biological nervous system processes information. The processing resembles cluster computer system, in a manner that processing ELEMENTS work in parallel to solve one specific complex problem. The artificial neural network learns as it processes, mimicking adjusting synaptic connections in the brain. The concept of neural networks predates the introduction of the personal computer. The first rudimentary artificial NEURON was produced by the neurophysiologist and analyst Warren McCulloch (1898–1969) and the logician and cognitive psychologist Walter Harry Pitts (1923–1969) in 1943. The neural network's learning aspect is represented as follows: the network adapts as follows: change the weight of an input by an amount proportional to the difference between the desired output and the actual output: $w_i = \eta * (D - Y) \cdot I_i$, where w_i is the weight of the "decision"/conclusion, η is the learning rate, I_i is the perception/input, D is the desired output, and Y is the actual output. This is referred to as the "perceptron learning rule" and was introduced in the early 1960s. Still, the learning process of the brain is mostly unknown; however, the basic operations by means of neurons, synapses, axons, and dendrites is anatomically described in great detail. In the biological neural network, there is a threshold that needs to be exceeded before a pulse is sent over the dendrites, leading to the cell NUCLEUS, before passing on to the axon that splits in a multitude of branches, causing a form of SIGNAL amplification by number of branches, which is subsequently passed on by SYNAPSE that communicates with the next network of dendrites and so on. A special neural network introduced by John Joseph Hopfield (1933–) in 1982 uses a similar recurrent artificial neural network, called an "associative

neural network.” The associative network of John Hopfield relies on content-addressable memory systems that are equipped with binary threshold nodes (see [Figure N.20](#)).

Figure N.20 (a) Advanced form of a neural network, adaption in the signal transmission, artist impression (b) robot “Asimo” developed by Honda relying on neural network.

Neuron

[biomedical, computational] Conducting and/or excitable CELL that propagates impulses based on membrane **DEPOLARIZATION** in binary format as pulse trains. Neurons are part of the nervous system, consisting of the autonomic and parasympathetic nervous system in the spine and diffusely distributed through the body of biological beings (animals and human), the brain and the senses (**HEARING**, smell, taste, touch, and **VISION** [sight]). Specialized neurons are found for muscular **ACTIVITY** and specific senses; they are referred to as the **MOTOR neuron** and sensory neuron, respectively, partially based on the specific chemical release from the **SYNAPSE**. Neurons are components of myelinated and nonmyelinated nerve cells, each conducting in respective fashion. **MYELINATED NERVE** cell are not excitable over the entire length, but only a certain point: the nodes of Ranvier. Nonmyelinated nerve cells can be excited at will at any location. The propagation process for the respective types of nerve cells is very different, the nonmyelinated neuron conducts continuously and the **MEMBRANE** depolarization propagation can be described by the **TELEGRAPH EQUATION** with respect to the **SIGNAL** transmission. The myelinated neuron depolarizes in jolts at the nodes of Ranvier, while the signal jumps without conduction, and propagates at least an order of **MAGNITUDE** faster than for the non-myelinated neuron (*see* **NERVE**) (see [Figure N.21](#)).

Figure N.21 Illustration of myelinated neuron.

Neurotransmitters

[biomedical, chemical, energy] Secretion of signaling molecules from the synaptic terminals of neurons (*see NERVE*) (*see* [Figure N.22](#)).

(a)

(b)

Figure N.22 (a,b) Typical structure of a chemical synapse in neural communications using neurotransmitter for signal relay between two or more nerve cells.

Neutrino

[atomic, general, high-energy, nuclear, quantum, solid-state] (ν^*), elementary PARTICLE with no CHARGE and negligible REST MASS compared to an electron is produced from the breakdown of a NEUTRON which balances its ENERGY (i.e., CONSERVATION OF ENERGY) with that of the emitted ELECTRON: $n \rightarrow p + e + \nu^*$, where n is a neutron, p is a PROTON, and e is an electron. In addition, the neutrino has a role in the CONSERVATION OF

MOMENTUM, SPIN, AND MASS. The electron and neutrino balance each other in such a way that when the electron ENERGY (i.e., KINETIC ENERGY) is high the neutrino energy is low and vice versa. The neutrino has an intrinsic ANGULAR MOMENTUM of $L = \hbar/2$, with $\hbar = h/2\pi$ the reduced PLANCK'S CONSTANT. The neutrino spins around the axis parallel to the direction of its MOTION. The rotational direction of the neutrino SPIN (clockwise/counterclockwise) is given by the RIGHT-HAND RULE. The neutrino has a counter part: the ANTI-NEUTRINO, which has the opposite spin given by the LEFT-HAND RULE (see Figure N.23).

(a)

(b)

Figure N.23 (a,b) Elementary neutrino release in the formation of deuterium resulting from a collision of two hydrogen atoms under high temperature and high pressure.

Neutrino (ν)

[atomic] Elementary PARTICLE released in the dissociation of a PROTON in a NEUTRON, a positron, and a neutrino: $\text{proton} \rightarrow \text{neutron} + \beta^+ + \nu$. Introduced by WOLFGANG PAULI (1900–1958) in 1931 and named in 1934 by ENRICO FERMI (1901–1954) and experimentally verified in 1959 by Clyde Cowan (1919–1974) and FREDERICK REINES (1918–1998). Neutrinos are very similar to the electron; however, they do not carry an ELECTRIC CHARGE, and it has an anti-particle (anti-neutrino: $\bar{\nu}$) (see [Figure N.24](#)).

Figure N.24 The release of a neutrino during a fusion process involving four hydrogen atoms.

Neutron

[atomic] Subatomic neutral (no net ELECTRIC CHARGE) particle of the hadron class. The neutron is generally part of the atomic NUCLEUS. The neutron was experimentally verified by JAMES CHADWICK (1891–1974) in 1932, because the newly discovered RADIATION could not be explained by gamma principles or alpha

particles. The neutron is composed of three quarks: one UP QUARK and two DOWN QUARKS. The MASS OF THE NEUTRON is marginally larger than the mass of the PROTON. The lifetime of the neutron outside of the atomic nucleus is only 885 s (see [Figure N.25](#)).

Figure N.25 (a,b) Neutrons involved in the uranium fission process.

Neutron cross section

[nuclear] Expression of the likelihood of a NUCLEON interaction, for a single collision the cross section of a neutron will depend on the PARTICLE involved in the interaction, size, charge and SPIN, and so on for nucleon-nucleon SCATTERING studies both experimental and theoretical information needs to be considered, specifically due to the Heisenberg uncertainty principles and WAVE functions involved. The cross section is a function of the “location” of the neutron (the NUCLEUS of the ELEMENT in question, type of nuclear reaction, the ENERGY (E) (including TEMPERATURE [T]), and the velocity (v) of both the incident particle and the nucleus with the imbedded neutron(s), as well as the relative ANGLE between the incident particle and the target nuclide. The standard unit for atomic, nuclear, and elementary particle cross section is the *barn* $= 10^{-28} \text{ m}^2$. The general cross section is the target area projection in the two-dimensional plane, perpendicular to the path of the incident PROJECTILE. The choice of “radius” is however not always that straightforward. One approximation would be the use of the Broglie wavelength of the neutron and the incident particle: $\lambda(E) = \hbar / \sqrt{2mE}$, where $\hbar = h/2\pi$ and $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ is Planck’s constant. Subsequently, the cross section (σ) becomes proportional to a combination of the effective radius of the physical object (R) of the size combined with the MOTION: $\sigma(E) \propto \pi(R + \lambda(E))^2$. Frequently, cross

sections are provided in tables in reference books particular to the application (e.g., NUCLEAR FISSION and scattering) (also see CROSS SECTION) (see Figure N.26).

Figure N.26 Diagram of the relation between neutron cross section and neutron energy, image source: CC-BY-NC-SA—DoITPoMS, University of Cambridge (http://www.doitpoms.ac.uk/tlplib/nuclear_materials/).

Neutron detectors

[nuclear] Neutron can be detected by scintillation counters, BUBBLE-, or IONIZATION chambers and specialized semiconductor detectors, although the lack of charge presents specific limitations. Generally, neutron detectors can only detect fast NEUTRON and often require a nuclear conversion process generating a charged PARTICLE. Certain materials used for detection are boron, gadolinium, helium, and LITHIUM, connected to a photo-multiplier or photocell.

Neutron star

[astronomy/astrophysics, quantum] Compact STAR with diameter of approximately 20 km, presumably one of various mechanisms a star can terminate. As the star completes burning its nuclear fuel, it will terminate by means of a SUPERNOVA explosion. The neutron star is a condensed version of a star that originally had a mass four to eight times the mass of our Sun and concurrently has a gravitational attraction that is in the order of 2×10^{11} times the earth's GRAVITATIONAL ACCELERATION. Based on this neutron star's density a tablespoon of star MATTER would

weigh in excess of 2×10^9 kg. Because of the complex charge structure, neutron stars also may carry a MAGNETIC FIELD that is in the order of 10^6 times stronger than fields experienced on EARTH (see Figure N.27).

Figure N.27 (a) The core of the Crab Nebula is a strong pulsar neutron star; part of the constellation Taurus. (b) The Crab Nebula is a remnant of a supernova that exploded presumably in the year 1054 (date of origin derived from spectroscopic analysis).

Neutron–proton chart

[atomic, nuclear] Chart describing the transmutation of a NEUTRON to a PROTON for a specific atomic number ELEMENT: proton converts into a neutron, releasing both a POSITRON (β^+) and a NEUTRINO (ν): $\text{proton} \rightarrow \text{neutron} + \beta^+ + \nu$, obeying all CONSERVATION LAWS. Ultimately, heavy radioisotopes will DECAY until they attain the extreme stability of the iron NUCLEUS. Note that in IRON the nucleons are the most tightly bound of all nuclei. The chart lists the BINDING ENERGY per nucleon displayed as a function of the atomic mass number (amu).

Newcomen, Thomas (1664–1729)

[general, mechanics] An English blacksmith. He is the inventor of the atmospheric reciprocating steam ENGINE in collaboration or in parallel with the works of THOMAS SAVERY (1650–1715), DENIS PAPIN (1647–1712), and JOHN CALLEY (1663–1717) approximately in 1712 (see Figure N.28).

Figure N.28 Thomas Newcomen (1664–1729).

Newton, Isaac, Sir (1642–1727)

[fluid dynamics, general, mechanics, nuclear, solid-state] An English scientist supporting the corpuscular theory of light as proposed by the ancient Greek philosophers, also the pioneer of MECHANICS (i.e., DYNAMICS). Newton postulated three laws of motion (Newton's first, second, and third laws) and one law on GRAVITY (Newton's LAW OF UNIVERSAL GRAVITATION) that define the concepts of modern PHYSICS (nonrelativistic). NEWTON'S FIRST LAW describes that any object will remain at rest without an external perturbation or remains in constant MOTION; NEWTON'S SECOND LAW defines that an object will accelerate under the influence of a force; NEWTON'S THIRD LAW describes the equal and opposite force experienced (e.g., floor exerts a force). Sir Newton indicated, as one of the first, that SURFACE WAVES in liquids can be defined mathematically in his 1687 *Principia* (see Figure N.29).

(a)

(b)

Figure N.29 (a) Sir Isaac Newton (1642–1727) and (b) stamp with the “infamous” apple that supposedly struck Isaac Newton on the head to initiate his thought process regarding the formalization of the concept gravity.

Newton (N)

[general] Unit of force, expressed in International Standard System (SI), kgm/s^2 . The definition was introduced based on the Newtonian system, specifically $F = ma$, force F equals the mass m multiplied by the acceleration a of that mass.

Newton's equation of motion

[general, mechanics, thermodynamics] A system of n particles, each with mass m_ζ , with representative position vector $\vec{r}_\zeta$ for the ζ th particle, and momentum $\vec{p}_\zeta = m_\zeta(d\vec{r}_\zeta/dt)$ can be described with a force ($\vec{F} = m(d^2\vec{r}/dt^2)$) combining the external force on each respective particle ($\vec{F}_\zeta^{\text{ex}}$) and the internal interaction between the particles ($\vec{F}_{\zeta\zeta'}$) as $d\vec{p}_\zeta/dt = \vec{F}_\zeta^{\text{ex}} + \sum_{\zeta' \neq \zeta} \vec{F}_{\zeta\zeta'}$. The system is subject to all CONSERVATION LAWS, including but not limited to conservation of momentum, CONSERVATION OF MASS, and conservation of force, introduced by SIR ISAAC NEWTON (1642–1727).

Newton's first law

[biomedical, general, mechanics] A body at rest remains at rest and a body in MOTION tends to remain in uniform linear motion at constant velocity. It was introduced by SIR ISAAC NEWTON (1642–1727). This is also called the LAW OF INERTIA because the constant velocity defines constant INERTIA. Generally, this translates in the condition that when the sum of the forces on an object are zero the body is compelled to stay in

constant uniform linear velocity. The “first law” also defines the concept of INERTIAL REFERENCE FRAME; the inertial reference frame can be external to the object or it can be assigned to travel with the object.

Newton's law for fluids

[fluid dynamics, mechanics, thermodynamics] For a NEWTONIAN FLUID the equation of force (F) per unit VOLUME (V) of a FLUID is defined as $\vec{F}/V = (1/V)(d\vec{p}/dt) = (1/\rho)(D\vec{v}/Dt) = (1/\rho)(\partial\vec{v}/\partial t) + \rho\vec{v} \cdot \nabla\vec{v}$, where $\vec{p}$ is the momentum vector, t the time, ρ the density, and $\vec{v}$ the velocity of FLOW as a vector field; where D/Dt represents the “substantive derivative,” and $\nabla = (d/dx) + (d/dy) + (d/dz)$ the gradient. This was introduced by SIR ISAAC NEWTON (1642–1727).

Newton's law of cooling

[thermodynamics] The rate of change of the temperature of a body of material is directly proportional to the difference between the TEMPERATURE (T) of the object (T_b) and the ambient temperature (T_a): $dT/dt = k_{\text{temp}}(T_b - T_a)$, where k_{temp} is the rate of cooling, and t time (*also see* FOURIER'S (CONDUCTION) LAW AND FICK'S LAW). This was introduced by SIR ISAAC NEWTON (1642–1727).

Newton's law of viscosity

[biomedical] Constitutive equation (not a fundamental law though) that is used to define the MOTION of primarily Newtonian fluids, under a restricted range of conditions. This was introduced by SIR ISAAC NEWTON (1642–1727). Sometimes interpreted as the RESISTANCE to deformation of solids as the shear modulus, which is the ratio of the shear stress to the shear strain: $E_{\text{mod}} = (\text{shear-stress})/(\text{shear-strain})$, and in fluids, the ratio of the shear stress to the rate of shear is $\mu = (\text{shear-stress})/(\text{rate of shear-strain})$.

Newton's rings

[optics] Interference pattern resulting from a variable gap DISTANCE between two surfaces, specifically when a plano-convex LENS is placed on a flat window pane. The air-gap (separation: t) with distance increasing with respect to the center of the contact location provides a reflection pattern where the path length back-and-forth between the first and second surface has a difference of multiple odd number of half-wavelengths will result in amplification (*Note:* the PHASE of the WAVE changes at the REFLECTION from AIR to glass, although the GLASS to AIR reflection does not incur a phase change): $2t = (m + (1/2))\lambda$, where λ is the wavelength of the light. When the optical path length differs by a whole number of wavelengths, the INTERFERENCE will create amplification (see Figure N.30).

Figure N.30 How Newton's rings are formed.

Newton's second law

[biomedical, general, mechanics] Placed in an INERTIAL REFERENCE FRAME a body with mass m will accelerate (acceleration a) with a MAGNITUDE proportional to the applied net force (F), moving in the direction of the force: $\sum \vec{F} = m\vec{a}$. This was introduced by SIR ISAAC NEWTON (1642–1727).

Newton's third law

[biomedical] An object experiencing an external force from another body will in turn exert a force equal in MAGNITUDE but opposite in direction on said initial body, also called “law of reaction” or in popular science terminology: “for every action there is an equal but opposite reaction.” This was introduced by SIR ISAAC NEWTON (1642–1727).

Newtonian fluid

[biomedical, fluid dynamics] Medium with linear VISCOSITY response as a function of the velocity gradient within the FLOW, that passes through the origin of the rheogram outlining velocity-gradient versus shear stress. Examples of Newtonian fluids in approximation are water and gases, while in practicality, there are no real perfect Newtonian fluids; however, under certain conditions, they are a close approximation; for instance, water will have a non-Newtonian BOUNDARY LAYER at a rigid WALL. Certain fluids may transition over into a Newtonian behavior when a shear-rate threshold is exceeded. BLOOD can act as a Newtonian liquid in the center of large vessels, while at low flow and small vessel diameter, blood is a pseudoplastic fluid. In close relation to the Newtonian fluid is the Bingham fluid, which has an offset from the origin, a flow-initiation threshold at minimum shear stress, a concept introduced by SIR ISAAC NEWTON (1642–1727) (also see VISCOSITY) (see Figure N.31).

Figure N.31 (a,b) Graphical representations of the concept of Newtonian liquid, with perfectly linear viscosity.

Newton–Cotes methods

[computational] Quadrature rule used to interpret the trapezoidal rule and can be generalized to represent higher degree polynomial interpolants. A function $f(x)$ in the domain $\{a, b\}$ can be developed in a series of polynomials and can be integrated precisely with the help of the Newton–Cotes quadrature rule. The function is developed as $f(x) = \sum_{j=0}^n f(x_j) \ell_j(t)$, where $\ell_j(t) = \prod_{i=0, i \neq j}^n (t - x_i) / (x_j - x_i)$, with $j = 0, 1, \dots, n$ being the Lagrange polynomial, where all data points are given nodes within the domain. The accuracy has a degree of at least n and the integral $\int_a^b f(t) dt$ is solved numerically. Newton number ($Ne = F_{\text{drag}} / \rho_f v^2 \ell^2$), dimensionless number representing the ratio of resistive (hydrodynamic DRAG $F_{\text{drag}} = m\ell/t^2$) to the net INERTIA force, where ρ_f is the density of the FLUID, v is the characteristic velocity, L is the characteristic length, m is the mass, and t is the characteristic time.

Newtonian mechanics

[general] Under nonrelativistic conditions MECHANICS has a straightforward correlation between space and time. Newtonian mechanics describes the classical mechanics of MOTION with all CONSERVATION LAWS intact as well as the three laws of Newton apply. These are concepts related to the work of SIR ISAAC NEWTON (1642–1727).

Newtonian reflecting telescope

[general, optics] Optical device designed by SIR ISAAC NEWTON (1642–1727) that relies on REFLECTION of light combined with REFRACTION of light to avoid the DISPERSION and CHROMATIC ABERRATION obtained from diffracting optical ELEMENTS (e.g., PRISM and lens) (see [Figure N.32](#)).

Figure N.32 Newtonian reflector telescope.

Newtonian theory of gravity

[general] See LAW OF UNIVERSAL GRAVITATION.

Nicholson, John Williams (1881–1955)

[astrophysics/astronomy, computational, general] A mathematician and astronomer from the United Kingdom/Great Britain who obtained astronomical SPECTROSCOPY and based on the observations of certain nebulae, in particular the CRAB NEBULA, proposed the existence of several ELEMENTS in 1911 that were at the time still undiscovered. However, his hypothesis was somewhat unfounded and the proposed “proto-elements” were never confirmed. The unconventional methods and bad results from Nicholson were however the lead for several confirmed discoveries and theoretical derivations on spectral line patterns.

Nier, Alfred Otto Carl (1911–1994)

[astrophysics/astronomy, atomic, nuclear] A physicist from the United States, and a pioneer in mass-spectroscopy device development and experimental observation. Nier designed the mass spectrometers used on the MARS space travel by Viking spaceships, in a miniaturized form (see [Figure N.33](#)).

Figure N.33 Alfred Otto Carl Nier (1911–1994) in 1940. (Courtesy of Elmer Anderson Library of the University of Minnesota, Minnesota, Minneapolis, MN.)

Niobium

[acoustics] Chemical ELEMENT, metal: $^{41}_{93}\text{Nb}$, formerly known as columbium. Niobium is widely used in superconducting alloys, which may also contain TITANIUM and tin. Specifically found in superconducting magnets used in MRI scanners.

Nipkow, Paul Gottlieb (1860–1940)

[general, nuclear] An engineer from Poland/Germany (Prussian Empire). He is the discoverer of the principle of television transmission in 1884 (see [Figure N.34](#)).

Figure N.34 Paul Gottlieb Nipkow (1860–1940) in 1884.

Nipkow disk

[general, nuclear] Spiral perforated disk used to display a sequence of images imbedded in a perforated disk that is illuminated by a lamp for projection on a wall designed by PAUL GOTTLIEB NIPKOW (1860–1940) in 1884. The concept of the Nipkow disk was used in 1928 by Scottish (Great Britain) engineer John Logie Baird (1888–1946) at the Baird Television Company based on the, by then, expired Nipkow patent in “emchanica” television transmission. The Nipkow disks were a popular pass-time for handheld IMAGE sequence viewing. Predating the Nipkow disk is the phenakistoscope (or “spindle viewer”), introduced in 1832 by physicist Joseph Antoine Ferdinand Plateau (1801–1883) from Belgium in collaboration with his sons. Coincidentally and independently, a similar device was introduced in the same year by Simon Ritter von Stampfer (1792–1864) from Austria, who had named his invention a stroboscope and the zoetrope (also named Daedaleum) by William George Horner (1786–1837) from Great Britain introduced in 1834. Prior to Plateau, MICHAEL FARADAY (1791–1867) and Peter Mark Roget (1779–1869) had designed a device called the “Michael Faraday’s Wheel,” consisting of two discs spinning in opposite directions. Even farther back, there is documented evidence that EUCLID (~300 BC) also described the same or similar concepts (see [Figure N.35](#)).

Figure N.35 (a) Nipkow disk patent application 1884 and (b) phenakistoscope disk by Eadweard Muybridge (1830–1904) in 1893.

Nitinol

[biomedical, solid-state] Metal alloy of equal portions of nickel and TITANIUM. Metallic compound that is sensitive to thermal stress and strain, providing a mechanism for flexible but sturdy structural support due to the difference in RESISTANCE to longitudinal and lateral strain. Nitinol alloys have the following unique properties: shape memory (return to the original shape after applying a specific elevated temperature) and superelasticity (10–30 times the ELASTICITY of the original metallic components). One specific application of nitinol is in vascular stents, to enlarge the vascular lumen under atherosclerosis, implemented under balloon angioplasty (see [Figure N.36](#)).

Figure N.36 (a,b) Nitinol stent concept used to expand the vessel lumen. (c) Nitinol stent maintains a flexible and wide pipe diameter.

Nitrocellulose

[biomedical, solid-state] Highly flammable mixture of nitric esters made by nitrating CELLULOSE. The nitrating process is mediated through exposure under nitric ACID or other nitrating agents. It is originally known as guncotton (because of its cotton-like POLYMER appearance), the main ingredient in gun powder. Nitrocellulose was used historically as an explosive (starter) or propellant. Additional applications are found as plasticizer in recording film strip (e.g., PHOTOGRAPHY and film), introduced by Kodak in 1889 (see [Figure N.37](#)).

Figure N.37 Strip of photographic film negatives on Nitrocellulose base.

Nitrogen (N₂)

[biomedical, general, geophysics, thermodynamics] Chemical ELEMENT, diatomic MOLECULE, gaseous under standard conditions: $^{14}_7\text{N}$, MELTING POINT: $-210^\circ\text{C} = 63\text{K}$. Nitrogen is the main component of the Earth's ATMOSPHERE, at approximately 78% of the total balance of gases. It was discovered by Daniel Rutherford (1749–1819) in 1772. Nitrogen is very versatile and is essential in the following: fertilizers, ammonia (NH₃), “super-glue” (cyanoacrylate), is part of Kevlar fabric, and is found in amino acids; it is also crucial component in nitroglycerin as an explosive LIQUID, which is additionally used as vasodilator (i.e., the chemical interaction will make the vessel WALL extend by releasing the muscular constraint in the medial layer in the

vessel wall and smooth MUSCLE, increasing the BLOOD flow) medication for HEART problems and other vascular concerns (*see* N¹⁴) (*see* Figure N.38).

Noble gas

[atomic, general] Monatomic ELEMENTS that were originally considered to be inert due to the OXIDATION number of zero (0). The six noble gases, all in group 18 (VIIIa) of the PERIODIC TABLE OF ELEMENTS are as follows: helium, neon, argon, krypton, xenon, and radon, all odorless and colorless with minimal chemical reactivity. In the 1960s, there were new discoveries that indicated the potential for chemical links with noble gases; in 1962, the first CHEMICAL COMPOUND of a noble gas was uncovered: xenon hexafluoroplatinate, by Neil Bartlett (1932–2008), and more thereafter. In the outer shell, all noble gases have the

maximum number of electrons allowed: two for Helium, and eight for all the remaining five elements, which is what makes these elements so stable. The term is an English translation from the German word “Edelgas,” introduced by Hugo Erdmann (1862–1910) in 1898 (see Figure N.39).

Figure N.39 Periodic table of elements highlighting the Noble gases in light green.

Nodal precession

[mechanics] Orbital precession of the rotation axis of a PLANET or moon. This phenomenon is responsible of the climatological changes on EARTH where the northern and southern hemispheres alternate in proximity to the Sun over the span of the conveniently chosen timescale of 1 year. The earth’s MOON has two precession motions: the first along the long axis precesses “eastward” just under 9 years (presumably caused by the solar “tide”), whereas the second precession is the orientation of lunar orbit inclination, which is the track along which the plane of the earth’s orbit intersects with the moon’s orbit. The first precession

pertains to the respective line of the apsides: perigee and apogee. The second, turning of the lunar orbit, has a period of approximately 18.6 years (see [Figure N.40](#)).

Figure N.40 Nodal precession.

Noddack, Ida Eva (1896–1978) (maiden name: Ida Eva Tacke)

[energy, general] A scientist from Germany. In 1935, Ida Tacke published the first work on the concept of ENERGY generation by NUCLEAR FISSION, while in 1925, she and her team uncovered two missing ELEMENTS in Mendelev's periodic table of elements; ELEMENT 75: rhenium and element 43: masurium (rejected by the scientific community for unknown reasons, and later attributed to Carlo Perrier (1886–1948) and EMILIO GINO SEGRE (1905–1989) as technetium, current name). Her discoveries were based on spectroscopic X-RAY using the equation from the work by HENRY GWYN JEFFREYS MOSELEY (1887–1915) for identification: $\nu = (3/4)R_y(Z-1)^2$, where ν represents the frequency, $R_y = 10973731.6 \text{ m}^{-1}$ is the RYDBERG CONSTANT, and Z is the atomic number (see [Figure N.41](#)).

Figure N.41 Ida Eva Noddack (maiden name: Ida Eva Tacke) (1896–1978).

Node of Ranvier

[biomedical, electromagnetism] Ionically permeable section in the WALL of MYELINATED NERVE cells between impermeable isolated segments, wrapped by Schwann cells. This anatomical phenomenon was described by the French histologist Louis Antoine Ranvier (1835–1922). The amount of ION exchange during DEPOLARIZATION is substantially less at the node of Ranvier than for a full length membrane depolarization under nonmyelinated nerve-cell activation pulse propagation, in the order of 200 times less. The reduced ion exchange provides one of the advantages in pulse propagation, next to the fact that a depolarization pulse “jumps” from node to node, instead of based on priming of the neighboring wall segment for nonmyelinated cells. Myelinated nerve cells propagation is at least an order of MAGNITUDE greater (see NERVE and MYELIN) (see [Figure N.42](#)).

Figure N.42 Node of Ranvier.

Noether, Amalie (Emmy) (1882–1935)

[computational, general] A mathematician and scientist from the Prussian Empire, Germany. The work of Amalie Noether involved the definition of the following three concepts: associative law (mathematical grouping can be interchanged, in rudimentary format: $(a + b) + c = a + (b + c)$ and $(a * b) * c = a * (b * c)$), commutative law (finding association between phenomena and functions characterized by substitution, interchange, or exchange: $a + b = b + a$ and $a * b = b * a$), and the distributive law (captured in essence as $a * ((b + c) = (a * b) + (a * c))$). Her work was far reaching and influential and she was commended by ALBERT EINSTEIN (1879–1955) for her mathematical contributions to his efforts. Noether created a theorem that

united the symmetry in nature and the universal laws of conservation: Noether's theorem, or NOETHER'S PRINCIPLE. Her mathematical efforts were influential in the uncovering of the HIGGS BOSON (see [Figure N.43](#)).

Figure N.43 Amalie (Emmy) Noether (1882–1935).

Noether's principle

[computational, energy, general, thermodynamics] For every conservation law, there is a continuous symmetry and alternatively for every continuous system, there is a symmetry that correlates to a corresponding conservation law. It was introduced by AMALIE NOETHER (1882–1935), also known as “Noether's theorem.”

Noise

[acoustics, general, optics, theoretical] Random fluctuations in the AMPLITUDE and/or frequency pattern resulting from characteristics of the phenomenon, such as temperature, external forces, external RADIATION, as well as other changing boundary conditions such as perturbation of reflective/SCATTERING media. Additional noise factors may come from the fact that the sensing mechanism used for QUANTIFICATION of the phenomena (providing the “SIGNAL”) is not able to remain in one single location. In certain cases, the measurements on an active system, biological or physical, will have changes in chemical equilibrium and chemical constituents

due to METABOLIC ACTIVITY (biological) or due to forced or passive DIFFUSION. The changes in chemical configuration can influence the accuracy of the measurement of another event/phenomenon due to the electrical interaction with the device or the wired or wireless communications of these observations. One significant noise factor in measurements on various levels are solar flares, which may even interact with the semiconductor materials used in a device. Acoustic noise can change the FREQUENCY SPECTRUM as, for instance, resulting from dust on a vinyl recording album played over STEREO equipment for reproduction of the authentic event. Optical noise can result from density changes as well as from thermal collisions and thermal emissions. Measurement of the brain's activities by electroencephalogram electrodes on the SKIN can be influenced by MOTION or sweat, and other MUSCLE activity such as EYE motion, as well as MACHINES switching in neighboring rooms (creating inductive INTERFERENCE). An indication of the stability of an event, measurement, phenomenon, or equipment is usually indicated by the signal-to-noise ratio, the higher the better. Noise in FLOW systems can result from unexpected TURBULENCE (see Figure N.44).

Figure N.44 (a,b) Television image distorted by electronic noise resulting from the interference in the line of transmission (primarily affecting analog signal only), or thermal effects in the processing electronics. During analog signal transmission moving conductive objects will reflect the signal stream of electromagnetic radiation, which in turn will also be captured by the antenna of the receiving instrument. Old-fashioned “rabbit-ear” antennas sitting on top of the television were notorious for interference noise, either induced by people walking through the room or a plane passing over the volume of air where the electromagnetic television wave transmission passed from transmitter to receiver station.

Nollet, Jean-Antoine (Abbé) (1700–1770)

[energy] A physicist from France. Nollet is most known for his invention of a device to measure (static) ELECTRIC CHARGE the ELECTROSCOPE. His work involved the use of the LEYDEN JAR as well, electrifying a group of 180 soldiers on display for King Louis XV. Abbé Nollet also phenomenologically described the phenomenon that the sharper an object, the greater the charge stream, that is, the electric field is a function of the radius of curvature of a CONDUCTOR in his attempts to describe the rudimentary principles of FLOW of electric MATTER and forces between electrically charged bodies in 1745, predating the fundamental work of his fellow countryman CHARLES AUGUSTIN DE COULOMB (1736–1806). His work coincided with the efforts of the American statesman and scientist BENJAMIN FRANKLIN (1706–1790), demonstrating LIGHTNING as a form of ELECTRICITY. Additional work of Jean-Antoine Nollet provided insight in the concepts of OSMOSIS,

illustrating how a SOLVENT passed selectively through a MEMBRANE, providing the foundation for the work by JACOBUS HENRICUS VAN'T HOFF (1852–1911) (see [Figure N.45](#)).

Figure N.45 Jean-Antoine (Abbé) Nollet (1700–1770).

Nomarski, Georges (Jerzy) (1919–1997)

[optics] An optical scientist and theoretician from Poland. Nomarski developed a special INTERFERENCE microscope, the “differential interference contrast (DIC) microscope,” using polarized light that is split in two perpendicularly POLARIZATION directions for enhanced contrast, split and recombined by an optical configuration of two Wollaston prisms. The Nomarski MICROSCOPE is a special form of PHASE contrast microscopy (see [Figure N.46](#)).

(a)

(b)

Nomenclature for nuclear reactions

[nuclear] A form of shorthand for the process of a nuclear reaction. For instance, the interaction of nitrogen with a NEUTRON forming radioactive carbon and PROTON in the Earth's ATMOSPHERE under cosmic radiation as ${}_0^1n + {}_7^{14}\text{N} \rightarrow {}_6^{14}\text{C} + {}_1^1p + \text{energy}$, or in "shorthand": ${}^{14}\text{N}(n, p){}^{14}\text{C}$ ("transfer reaction"), where the first item in brackets refers to the PROJECTILE. Note that ${}^{14}\text{C}$ can be used for radioactive dating, due to its integral incorporation in all biological media. The nomenclature for the interaction process has the following classifications: compound reaction, direct reaction, INELASTIC SCATTERING, knock-out reaction, nuclear photoeffect, nuclear scattering, RADIATIVE CAPTURE, resonance reaction, RUTHERFORD SCATTERING, and transfer reaction.

Nonadiabatic process

[atomic, solid-state, thermodynamics] A process in theoretical chemistry that involves the interaction in a molecule that hold the exchange between electronic and nuclear vibrational MOTION, referred to as "vibronic coupling." Vibronic coupling pertains to the MIXING of electronic states of the MOLECULE as a result of small vibrations and is tied to the derivative of the WAVE function for the configuration. Nonadiabatic chemical processes occur at the conical intersections. In a molecular ENERGY configuration when two potential energy surfaces are degenerate and intersect the energy state in conical intersect. At this point the nonadiabatic coupling between these two energy states is also nonvanishing. The energetic BOUNDARY LAYER surrounding the conical intersect no longer obeys the BORN–OPPENHEIMER APPROXIMATION, supporting the nonadiabatic conditions. Nonadiabatic effects, specifically involve the splitting and SCATTERING of the wave packet (QUANTUM effect dominated solution to the time-dependent SCHRÖDINGER EQUATION) at potential energy surface crossings, such as associated with TUNNELING. Chemical interactions that can be described by the conical intersection are photoelectric reactions, combustion, and explosion, for instance. One specific example of the conical intersect is the stability of DNA (DNA molecule encoded with a range of biological properties: genetic structure) under irradiation by ULTRAVIOLET light, where the "excited" electrovibrational state of the molecular wave packet will "roll-back" to the electronic GROUND STATE on the conically curve potential energy surface of the molecular binding. The number of vibrational DEGREES OF FREEDOM is directly related to the number of atoms making up the molecule; for instance, a diatomic molecule has two degrees and consequently progressively upward. On a nuclear level, similar principles will apply; only in this case, the energy potentials are outlined by the PROTON and neutron interactions (see Figure N.47).

Figure N.47 Nonadiabatic processes occur on electronic and macroscopic scale: (a) nuclear vibration energy diagram. (Continued)

Figure N.47 (Continued) Nonadiabatic processes occur on electronic and macroscopic scale: (b) atmospheric nonadiabatic thermal inversion.

Nonconductor

[general] See INSULATOR.

Nondegenerate ground-energy value

[quantum, thermodynamics] Ground state of a quantum-mechanical energy system. A quantum MECHANICAL ENERGY level is said to be degenerate if two or more different measurable states exist simultaneously, where the number of corresponding states indicates the degree of DEGENERACY for a specific energy level. This is represented by a single EIGENVALUE solution for the Hamiltonian of several independent eigenstates. For a nondegenerate state, the condition is that the eigenvalue in its eigenspace is one dimensional. By definition, the GROUND STATE is the only energy state that can be nondegenerate, because there is no change in conditions at this energy, but this not exclude degenerate ground states from occurring. Theoretically, this can be illustrated by the density functional theory, which provides the electronic structure of atoms, molecules, and solids in their ground states. The electronic density distribution plays a central role, defining the degenerate ground states, SPIN density (describing spin-up and spin-down densities as well as PARAMAGNETISM or cooperative MAGNETISM), as well as multicomponent systems (e.g., nuclei and electron–hole assemblies in semiconductor).

Nondimensional groups

[computational, fluid dynamics, thermodynamics] Dimensionless analysis is a mathematical technique used to determine the relationships between several variables and hence predict physical parameters that influence the fluid FLOW, HEAT TRANSFER, and other transfer process. By converging to the basic MLT units (kg, m, s), the elementary concepts become dimensionless. The LAW OF SIMILARITY allows the principles to be applied in analogy between FLUID DYNAMICS, THERMODYNAMICS, or various other aspects of engineering and physics. Examples of dimensionless parameters are the REYNOLDS NUMBER, Froude number, Weber number, and MACH NUMBER.

Nondispersive component

[biomedical, solid-state] The free ENERGY at the interface surface of a medium with another medium. The nondispersive free energy is the geometric mean of the free energy of medium 1 (for instance, a solid) and medium 2 (for instance, a LIQUID). The free energy can, for instance, be derived from Fowkes' expression and the Young's equation for the respective medium.

Nondispersive wave

[acoustics, mechanics, optics] Wave propagation in a nondispersive medium, with no inherent deformation. DISPERSION stands for the variability in propagation velocity with respect to direction of propagation, governed by the WAVE EQUATION in one dimensional: $(\partial^2 \chi(x, t) / \partial t^2) - v^2 (\partial^2 \chi(x, t) / \partial x^2) = 0$, or multidimensional: $\partial^2 \tilde{\chi} / \partial t^2 - v^2 \nabla^2 \tilde{\chi} = 0$ for a wave phenomenon χ with (PHASE) velocity of propagation v , where the velocity is independent of the wavelength. The wave equation is generally solved by SEPARATION OF VARIABLES, taking the real part $\chi(x, t) = \text{Re}[\tilde{\chi}(x) * t(t)]$. Nondispersive waves maintain both the spectral and temporal information (see [Figure N.48](#)).

Figure N.48 A nondispersive wave can be generated by a single wavelength emitter, such as a laser; in contrast to broad band emitters which will be subject to dispersion at certain gradients or discontinuities with the medium of transmission. Dispersion of white light from a prism. In contrast a laser beam can hold its coherence for light years, spanning across the galaxy, as used in remote sensing, collecting the returning signal from great distances with embedded encoding that can be resolved by interferometric analysis. Certain mechanical waves can be nondispersive, under well-defined boundary conditions, for instance, in a perfectly homogeneous medium (free-space [atmospheric], at uniform temperature and pressure) or single wavelength acoustical sensing.

Nonelastic

[biomedical, mechanics, nuclear] Rigid material that will have a yield strength at which it will break without deformation. In nuclear collision, the nonelastic CROSS SECTION refers to the steady-state target cross section of nuclides solely based on the physical size and interactions with inherent loss of kinetic ENERGY (i.e., inelastic) (see COMPTON SCATTER) (see Figure N.49).

Figure N.49 Rigid, nonelastic hard-shell model of the atom, specifically the nucleus.

Nonequilibrium state

[thermodynamics] The broad range of conditions defining chemical reactions and transport processes (e.g., ENERGY and material).

Nonideal mixture

[thermodynamics] Mixture composed of components that do not behave as an IDEAL GAS or operate at PHASE transitions. According to the ideal GAS LAW, the pressure of the constituents of a mixture should change linearly with temperature and volume, assuming a fixed quantity. In parallel, for liquids, an ideal liquid obeys RAOULT'S LAW, linking the VAPOR PRESSURE to the individual contributions of the respective components. For liquids, the PHASE DIAGRAM of nonideal mixtures introduces the concept of an azeotropic mixture. In an azeotropic mixture, the vapor state has the exact same composition as the LIQUID state, so that the components cannot be extracted by simple DISTILLATION.

Non-Newtonian fluids

[fluid dynamics] Every fluid, the NEWTONIAN FLUID is a theoretical idealistic condition, specifically pertaining to the VISCOSITY aspects (see NEWTONIAN FLUID and VISCOSITY).

Nonohmic electrical devices

[general] Devices that do not obey OHM'S LAW: $V = IR$, where the voltage drop (V) is directly linked to the CURRENT (I) through a RESISTANCE (R). Example of a nonohmic device is a doped silicon DIODE; the voltage current diagram is not linear, but has a logarithmic correlation and specifically, the resistance is

not a constant. For a DIODE, the resistance is generally different for the direction of current, sometimes by orders of MAGNITUDE.

Nonpolar nature of a medium

[biomedical, chemical, fluid dynamics, mechanics, thermodynamics] Materials (especially liquids) can on a molecular level be electronically inert with neutral charge across the MOLECULE. Oil is a clear example of the natural nonpolarity. Water is a polar liquid. Detergents have a polar and a nonpolar side to the molecule, making them ideal for acting as a degreaser while dissolved in water.

Nonrelativistic energy

[nuclear] Even for nuclear events, a range of ENERGY can be identified for which a nonrelativistic approach will yield only a small error, in the order of 1%. This generally applies to ALPHA DECAY, which is nonrelativistic for the momentum; however, beta DECAY is relativistic for the momentum. On the energy level, electrons operate nonrelativistically when $KE < 20.7$ keV, and for protons, the phenomena can be treated nonrelativistic when $KE < 38$ MeV (*also see ENERGY*). The nonrelativistic prediction of the DIRAC EQUATION for the nonrelativistic coulomb problem has the following expression, using a SCALAR potential resulting from the NUCLEUS ($\phi = A_0$): $((\vec{p}^2/2m) - (Ze^2/4\pi r) - (\vec{p}^4/8m^3c^2) + (Ze^2\{\vec{L} \cdot \vec{S}\}/8\pi m^2c^2r^3) + (Ze^2\hbar^2/8m^2c^2)\delta^3(\vec{r}))\Psi = E^{nr}\Psi$, where $E^{nr} = E - mc^2$ is the nonrelativistic energy, $\vec{p} = m\vec{v}$ is the momentum, m is the mass of the PARTICLE, v is the velocity, Z is the charge number, $e = 1.60217657 \times 10^{-19}$ C is the coulomb charge, r is the separation DISTANCE, $\vec{L}$ is the ORBITAL ANGULAR MOMENTUM, $\vec{S}$ is the spin, $c = 2.99792458 \times 10^8$ m/s is the speed of light, $Ze\delta^3(\vec{r}) = \nabla \cdot \vec{E}$, $\hbar = h/2\pi$ with $h = 6.62606957 \times 10^{-34}$ m²kg/s Planck's constant, and Ψ the "Schrödinger" wavefunction. The phenomena are determined by the fact that nonrelativistic particles have continuous and discrete DEGREES OF FREEDOM (with respect to momentum, for instance, as a continuous reference frame and SPIN component for the discrete reference frame).

N

Normal compressive strain (ϵ_{nc})

[general, mechanics] Strain of an object under compression, in contrast to TENSILE STRAIN, but no difference in expression (*see NORMAL STRAIN*) (*see Figure N.50*).

Figure N.50 Vice applying normal compressive strain.

Normal distribution

[atomic, computational] Probability density function for events and measured values: $f_{\text{normal}}(x) = 1/(\sigma_{\text{stat}}\sqrt{2\pi})\exp[-(1/2\sigma_{\text{stat}}^2)(x - \mu_{\text{stat}})^2]$; where μ_{stat} is the mean value of the observation x and σ_{stat} is the statistical variance. Generally, the variance can be derived as follows:

$\sigma_{\text{stat}}^2 = 1/(n-1) \sum_{i=1}^n (x_i - \mu_{\text{stat}})^2$, with n values. This is closely linked to the GAUSSIAN DISTRIBUTION. The standard normal distribution has as conditions $\sigma_{\text{stat}}^2 = 1$ and $\mu_{\text{stat}} = 0$ (see Figure N.51).

Figure N.51 Plot of the normal distribution, plotting the function $f(x)$ as a function of a variable “ x ” around the center point “69”.

Normal force (F_n)

[biomedical, general, mechanics] Resiprocating force in response to an applied force, normal to the surface; perpendicular to the surface. The force of a table top in response to a object resting on the table yields the normal force in equivalence to NEWTON’S THIRD LAW. Friction is a direct function of the normal force: $f_K = \mu_K F_n$, where μ_K represents the KINETIC FRICTION coefficient for kinetic friction force f_K (see Figure N.52).

Figure N.52 Normal force.

Normal strain (ϵ_n)

[biomedical, mechanics] Fractional change in body length (ℓ) as a result of an applied normal STRESS: $\epsilon_n = \Delta\ell/\ell$, a rod under tension is under TENSILE STRAIN while a rod under compression is under compressive strain (see Figure N.53).

Figure N.53 Normal strain.

Normal stress (σ_n)

[biomedical, mechanics] Ratio of normal force (F_n) applied on a body and in the cross-sectional area (A) the applied force is normal to $\sigma_n = F_n/A$, when the body is under tensile force the stress is considered TENSILE STRESS, and alternatively under compression compressive stress. The difference between pressure and stress is in the fact that pressure is a SCALAR quantity and stress is a TENSOR (see Figure N.54).

Figure N.54 Normal stress.

Normal Zeeman effect

[atomic, nuclear, quantum] See ZEEMAN EFFECT, NORMAL.

Normalization

[atomic, computational, general] Process of unification of the combined results by incorporation of a coefficient that renders a peak of the PROBABILITY distribution of an event or the range of data to unity.

Norman, Robert (1550–1600)

[general] A seaman and maritime scientist from Great Britain who invented the concept of navigation by means of a magnetic compass in 1581, describing the LODESTONE (also found as “loadstone,” a MAGNET) and ensuing practical applications to navigation. Note that the magnetic properties were known to the ancient Greek, well before the introduction in seafaring navigation. Robert Norman discovered the fact that the compass needle is influenced by the fact that the earth’s MAGNETIC FIELD does not run parallel to the earth’s surface, causing a deviation called “magnetic inclination.” The MAGNETIC inclination is the ANGLE that the magnetic field makes with the horizontal as a function of the LATITUDE (see [Figure N.55](#)).

Figure N.55 Magnetic dip as outlined and described by Robert Norman (1550–1600).

North

[electromagnetism, general, geophysics] Colloquial reference to the direction indicated by the compass needle. (see **MAGNETIC NORTH POLE**). In **MAGNETIC** devices, this indicates the location of the device where the **MAGNETIC FIELD** lines emerge to loop around in three-dimensional space to terminate on the South Pole of the device (see [Figure N.56](#)).

(a)

(b)

Figure N.56 (a) A compass pointing north and (b) ice-field found at the north-pole. There is no lands at the north pole, in contrast to the land found at the south-pole.

North geographic pole

[general] See **GEOGRAPHIC NORTH POLE**.

North magnetic pole

[general] See **MAGNETIC NORTH POLE**.

Northern Light

[astrophysics, atomic, energy, geophysics] See *AURORA* and *AURORA BOREALIS*.

Nozzle

[fluid dynamics, mechanics, thermodynamics] A duct with a variable CROSS SECTION. Because of the change in the cross-sectional area (A) as a function of location in the FLOW of a fluid, the flow can be regulated and directed, achieving, under certain conditions, acceleration and forming a high-velocity (v) stream. The FLUID velocity distribution can be explained by the principles of CONSERVATION OF MASS (m), more specifically for an INCOMPRESSIBLE FLUID: $dm/dt = \rho v A$. A nozzle converts potential ENERGY confined by the work performed under PV , where P is the pressure and V the volume, into kinetic energy. Nozzle provides flow that is nearly adiabatic and result in little or no change in potential energy and require no shaft to convey the work. The change in ENTHALPY (H) across the nozzle is $\Delta H = (v_0^2 - v_1^2)/2g$, where v_0 is the exit flow velocity, v_1 is the flow velocity before the nozzle, and g is the GRAVITATIONAL ACCELERATION. The throat is the narrow section of the nozzle, after which it may expand or not. Under certain conditions, the outflow from the nozzle may reach Mach conditions, specifically when: $P_0/P_1 \cong (1 + 0.2Ma_c^2)^{-3.5}$, where P_1 is the pressure in the reservoir leading to the nozzle, P_0 is the external pressure, and Ma_c is the MACH NUMBER on exit from the nozzle. The maximum flow rate is achieved when the velocity in the throat, with cross section A_t reaches sonic speed, providing: $(dm/dt)_{\max} = 0.0404(p_1/\sqrt{T_1})A_t$, where T_1 is the ABSOLUTE TEMPERATURE in the reservoir. The ISENTROPIC efficiency of a nozzle, if defined by the difference between the actual velocity (v_a) and the isentropic velocity (v_{is} , presumed constant ENTROPY [S]) on exit is $\eta_{\text{nozzle, is}} = (v_{a,0}^2/2g)/(v_{is,0}^2/2g) = v_{a,0}^2/v_{is,0}^2$, where the isentropic velocity follows from the entropy (S) versus enthalpy (H) diagram for the flow. The adiabatic efficiency is defined as $\eta_{\text{nozzle, adiabatic}} = (H_{is,0} - H_{is,1})/(H_{a,0} - H_{is,1})$. ADIABATIC COMPRESSION is exemplified by TEMPERATURE (T) versus entropy (S) diagram, respectively enthalpy (H) versus entropy (S) diagrams (see Figure N.57).

Figure N.57 (a) Jet engine nozzle, (b) adiabatic compression at the nozzle described by a TS phase diagram, (c) HS diagram, and (d) TS diagram for adiabatic compression processes.

npn transistor

[electronics, general] Standard design semiconductor TRANSISTOR that has a P-TYPE SEMICONDUCTOR (electron deficit, holes) material sandwiched between two electronegative semiconductor materials, with excess electrons (predominantly silicon or germanium). The segments of the npn transistor are collector, base, and emitter, in sequence of current FLOW, where the base is controlled by an externally applied electrical potential and regulates the current flow from the collector to emitter. The current flow is regulated by the Fermi levels at the respective *pn*-junctions for the lightly doped collector and heavily doped emitter. The lesser used PNP TRANSISTOR is the alternative (see [Figure N.58](#)).

Figure N.58 Transistor, functional diagram.

NSOM

[optics] See NEARFIELD SCANNING OPTICAL MICROSCOPE.

n-type doping

[atomic, electronics, general] The process of administering an excess amount negative ions in a semiconductor matrix. The process changes the ENERGY BANDS (e.g., FERMI LEVEL) of the medium, in particular at the boundary with a *p*-type doped medium in a DIODE or TRANSISTOR configuration (*also see pn-JUNCTION*) (see Figure N.59).

Figure N.59 N-type semiconductor, doped with antimony as electron-donor.

n-type semiconductor

[electronics, general] Electronegative semiconductor materials, with excess electrons (base predominantly silicon or germanium) achieved by DOPING with phosphorus (P), arsenic (As), or antimony (Sb) (*see pn-JUNCTION, npn TRANSISTOR, and SEMICONDUCTOR*).

Nuclear adiabatic (de-)magnetization

[atomic, nuclear] A procedure that is used to change the temperature of a system by changing the local absolute value of the MAGNETIC FIELD strength. This process was discovered independently by both PETER DEBYE (1884–1966) in 1926 and William Francis Giaque (1895–1982) in 1927. The nuclear ADIABATIC DEMAGNETIZATION provided a tool to lower the temperature well in the decimal numbers below 1 K near the ABSOLUTE ZERO. In this situation, the mechanism of action relies on the existence of some form of disorder that can be organized by configuring MAGNETIC DIPOLE seeds. The magnetization M of a medium results from circulating electric (eddy) currents on a MACROSCOPIC scale or on an atomic level by elementary atomic magnetic moments. Magnetization is defined as the magnetic moment per unit volume of these collective currents or moments. The units are gauss in the electromagnetic system of units (emu) and weber per square meter in the mks system, respectively: $1 \text{ (weber/m}^2\text{)} = (1/4\pi)10^4 \text{ gauss}$.

Nuclear angular momentum

[nuclear] See ANGULAR MOMENTUM, SPIN.

Nuclear atom

[general] Atomic model developed in 1911 by ERNEST RUTHERFORD (1871–1937) based on a small NUCLEUS with POSITIVE CHARGE surrounded by an orbiting cloud of electrons. This model is primarily based on phenomenological observations and data and was a marked improvement on the “plum pudding model” introduced in 1904 by JOSEPH JOHN THOMSON (1856–1940), of whom Rutherford was a student.

This is different from the Bohr model, which has more theoretical and far-reaching implications. The Rutherford model was based on the scattering CROSS SECTION of a thin sheet of METAL (e.g., gold) bombarded by alpha particles. The RUTHERFORD SCATTERING cross section for the nuclear atom is as follows: $d\sigma_{\text{Ruth}}/d\Omega = \left(Z_1 Z_2 e^2 / 8\pi\epsilon_0 m v_0^2 \right)^2 \csc^4(\theta/2)$, where σ_{Ruth} is the SCATTERING cross section as a function of the SOLID ANGLE OF PERCEPTION Ω for a target with charge number Z_2 and incident ballistic charge number Z_1 for electron charge $e = 1.60217657 \times 10^{-19} \text{ C}$ and ballistic mass m , measured with angle θ under PROJECTILE velocity v_0 , with ϵ_0 being the permittivity of free space (see Figure N.60).

Structure of the atom
Rutherford atomic model

Figure N.60 Rutherford's atomic model of the nuclear atom, solid nucleus with no distinguishable constituents.

Nuclear binding energy

[atomic, nuclear] The nucleus contains approximately 99.975% of the total mass of an ATOM and hence the ENERGY requirements for dissociation are very high. The NUCLEAR BINDING ENERGY is the energy contained by holding the appropriate number of protons and neutrons together, and the energy released when a grouping of protons and neutrons is split off from the NUCLEUS. The total binding energy (BE) can be derived from the MASS ENERGY equivalence: $BE = \left[Zm_p + (A - Z)m_n - {}_Z m^A \right] c^2$, where Z is the number of protons (the atomic number) with m_p being the respective mass, A the atomic mass (with $A - Z$ the number of neutrons, with mass m_n), c the speed of light, and ${}_Z m^A$ the sum of the rest of the masses of the respective protons, neutrons, and remaining nucleus.

Nuclear bomb

[nuclear] An explosive device that releases nuclear ENERGY based on nuclear reactions of either fission or FUSION. The first fission bomb experimentally tested in 1945 (also referred to "ATOMIC BOMB") released approximately 20 kton (kilo-ton) of TNT (the explosive energy yield equivalent to the detonation of 20,000 ton {metric ton} of TNT); where 1 ton TNT = 4.184 GJ. The most popular isotopes used in the fission process are uranium-235 (enriched uranium) and plutonium-239. The first fusion bomb ignited in 1952, also referred to as "thermonuclear bomb" (the "hydrogen" bomb, which is actually a fission–fusion mechanism) released approximately 10 Mton TNT. The HYDROGEN BOMB uses uranium fission as the "detonator" for the hydrogen fusion process. The use of the description "atomic bomb" (A-BOMB) is a misnomer because the energy comes from the NUCLEUS. The FISSION process becomes self-sustaining when a critical mass of unstable medium is exceeded, slightly more than 10 kg of plutonium-239 surrounded by the U-238 ISOTOPE. The H-BOMB relies on the heat and pressure of fission initiated by the uranium explosion initiating the following process. Hydrogen-2, or {deuterium (${}^2\text{D}$)} fuses with hydrogen-3 {tritium (${}^3\text{T}$)} and

forms helium-4 (^4He) as well as one neutron (n) and energy ($E \approx 17.6 \text{ MeV} = 2.81983075 \times 10^{-12} \text{ J}$) that is converted in THERMAL EXPANSION and ELECTROMAGNETIC RADIATION: $^2\text{D} + ^3\text{T} \rightarrow ^4\text{He} + n + E$. Note that 1 kg of hydrogen contains 5.975×10^{26} atoms (see Figure N.61).

Figure N.61 Rendering of the (a) “Little Boy” atomic bomb targeted to be dropped on Hiroshima, Japan, on August 6, 1945 and (b) Boeing B-29 bomber: Enola Gay, used to deploy the “atom bomb” over Hiroshima, Japan as well as participated on the attack on Nagasaki, Japan, which resulted in the termination of the war offensive by Japan during the Second World War (1940–1945), (c) rendering of the pressure evolution, and condensation and debris “mushroom” cloud resulting from an above ground nuclear explosion.

Nuclear charge

[nuclear] Total charge resulting from the number of protons in the nucleus of an ATOM. The nuclear charge is indicated by the PROTON number Z (atomic number). This charge will affect the BINDING ENERGY of the electrons in their respective orbits. The charge configuration can be determined with the use of elastic electron SCATTERING cross sections and Bayesian probability distributions.

Nuclear coulomb barrier

[general] Because of the charge distribution of the NUCLEUS, an electric POTENTIAL BARRIER is created that can be accessed by TUNNELING or under FUSION the kinetic ENERGY of the incident PARTICLE needs to exceed the coulomb barrier. For fusion to overcome the electric repulsion, the fusing particle will need to get close enough to allow for the attractive nuclear strong force to be activated. The energy barrier is derived from the electrostatic potential energy: $U_{\text{Coulomb}} = (1/4\pi\epsilon_0)(q_1q_2/r) = (1/4\pi\epsilon_0)(Z_1Z_2e^2/r)$, where

ϵ_0 is the permittivity of free space, r is the separation between the two charges q_1 and q_2 , with the charge MAGNITUDE defined by the atomic number Z (also see QUANTUM TUNNELING).

Nuclear fission

[atomic, nuclear] Special type of nuclear transformation characterized by the splitting of a NUCLEUS into at least two other nuclei and the release of a relatively large amount of ENERGY. The most well-known FISSION process is that of uranium-235 (see FISSION) (see Figure N.62).

Figure N.62 Nuclear fission.

Nuclear force

[general] Nuclear forces can be distinguished as strong and weak nuclear forces, as part of the four principle force, including gravitational force and electromagnetic force. Weak nuclear force has a range of $10^{-17} \text{ m} = 10 \text{ am}$ (attometer) working between atomic constituents, quarks and leptons, and the strong force has a range of $10^{-15} \text{ m} = 1 \text{ fm}$ (femtometer), acting between subnuclear particles: quarks and gluons. Apart from the coulomb force acting between opposite and like charges, attractive and repulsive, respectively, the nucleon–nucleon force generally becomes negligible for a separation greater than $4 \times 10^{-15} \text{ m} = 4 \text{ fm}$ and is generally strong at smaller DISTANCE than 1 fm, stronger than the prevailing coulomb force:

$F_c = (1/4\pi\epsilon)(Z_1Z_2/r^2)$, where Z_i represents the respective charge on the two particles at distance r and $\epsilon = \epsilon_r\epsilon_0$; $\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{Nm}^2$ the DIELECTRIC permittivity, in VACUUM: “ ${}_0$,” and ϵ_r is the relative

permittivity. The large scale nucleon–nucleon attraction between the respective neutron–neutron, neutron–proton, or proton–proton configurations can be described in first order approximation by the SCHRÖDINGER EQUATION: $-(\hbar^2/M)\nabla^2\psi + V_{\text{elec}}\psi = i\hbar(\partial\psi/\partial t)$, where ψ is the two-nucleon WAVE FUNCTION, $\hbar = h/2\pi$, where $h = 6.63 \times 10^{-34}$ Js is Planck's constant, V_{elec} is the electrical potential of the BINDING ENERGY, $M = 939 \text{ MeV}/c^2$ is the NUCLEON mass (with a negligible difference between the PROTON and NEUTRON mass), ∇^2 is the Laplace operator representing the second order derivative in all dimensions, and t is the time. The potential V_{elec} is a function of the nucleon separation $\vec{r}$, the orientations of the spins of the two interacting nucleons $S^{(a)} = (1/2)\hbar$ and $S^{(b)} = (1/2)\hbar$, each with a SPIN component in the z -direction $S^{(i)} = \pm(1/2)\hbar$, yielding four possible spin configurations, each resulting in a 4×4 matrix for the potential and three matrix solutions for the three nucleon interaction combinations. In molecular PHYSICS, the interaction between two nucleons with the release of a PION (“ π ”) (i.e., π -meson), with mass m_π being represented by the potential equation: $V = \tau_a \cdot \tau_b g_\pi^2 (m_\pi/2M) \left[(1/3)(e^{-\mu_c r}/r)(\vec{\sigma}_a \cdot \vec{\sigma}_b) + ((1/3) + (1/\mu_c r) + (1/\mu_c^2 r^2))(e^{-\mu_c r}/r) S_{ab} \right]$, where $1/\mu_c = \hbar/m_\pi c = 1.4 \text{ fm}$ is the pion COMPTON WAVELENGTH, $\sqrt{g_\pi^2/\hbar c} \equiv$ is the pion-nucleon coupling constant, $\hbar = h/2\pi$, where $h = 6.6260 \times 10^{-16}$ Js is Planck's constant, $\vec{\sigma}_a$ and $\vec{\sigma}_b$ are the PAULI SPIN MATRICES for the respective nucleons a and b , τ_a and τ_b are the respective isospin matrix in 2×2 format for nucleon a and b , r is the nucleonic interspacing distance, c is the speed of light, g_π is the pion ENERGY, and $S_{ab} = 3(\vec{\sigma}_a \cdot \vec{r})(\vec{\sigma}_b \cdot \vec{r}) - (\vec{\sigma}_a \cdot \vec{\sigma}_b)$ is the TENSOR operator; the intrinsic spin can also be characterized as $S^{(a)} = \vec{\sigma}_a \hbar/2$.

Nuclear fusion

[atomic, nuclear, thermodynamics] The coalescing of two or more nuclei to form a new NUCLEUS with relative stability. The FUSION process requires penetrating the NUCLEAR COULOMB BARRIER, placing a high velocity constraint on the process, hence only operational under very high temperatures. The fusion process relies on QUANTUM TUNNELING, a process discovered in 1929 by German physicist Friedrich Hund (1896–1997). In the fusion process, some of the combined mass is converted into ENERGY, yielding a high energy EXOTHERMIC REACTION. The first successful attempt in nuclear fusion was made in 1932 by Australian physicist Mark Oliphant (1901–2000) with hydrogen isotopes. Substantial focused research was initiated in the early 1940s in the United States as part of the MANHATTAN PROJECT. Additional research in the development of THERMONUCLEAR FUSION for civil purposes was initiated in the early 1950s (see Figure N.63).

Figure N.63 Nuclear fusion.

Nuclear g-factor (g_n)

[atomic, energy, nuclear, optics] The spectral split under influence of the nuclear SPIN is determined by the influence of the nuclear spin and the interaction with the electron orbital MAGNETIC FIELD (see G-FACTOR, NUCLEAR. Also see ZEEMAN EFFECT and HYPERFINE STRUCTURE).

Nuclear magnetic moment

[atomic, nuclear] $\mu_{I_n} = g_n (m_e/M_n) (e/2mc) \vec{I}$, with g_n the nuclear g-factor, (m/M) the ratio of the electron mass (m_e) over the nuclear mass (M_n) and $\vec{I}$ the nuclear SPIN.

Nuclear magnetic resonance (NMR)

[general] See MAGNETIC RESONANT IMAGING (MRI).

Nuclear magneton (nm)

[atomic, nuclear] The MAGNETIC MOMENT (MM) associated with the intrinsic spin of nuclear particles is expressed in unit nuclear magneton: $nm = (e\hbar/2m_p) = 5.0505 \times 10^{-27} \text{ Jm}^2/\text{Wb}$; for a PROTON, this is $MM_{\text{proton}} = 2.79275 \text{ nm}$, and for the NEUTRON, $MM_{\text{neutron}} = -1.9135 \text{ nm}$.

Nuclear medicine

[atomic, biomedical, computational, general, imaging, solid-state] Therapeutic applications that use radioactive isotopes to create selective modifications to the biological DNA or cause CELL death as well as rely on the selective incorporation of radioactive isotopes in a metabolic event to be used for imaging purposes. In imaging, the use of iodine ISOTOPE is one of the mechanisms that allow for monitoring the ACTIVITY of the thyroid by means of a gamma CAMERA. Another application in positron emission TOMOGRAPHY imaging is the use of fludeoxyglucose isotope (active component: positron emitting fluorine-18), known as “fluorodeoxyglucose” as a RADIOPHARMACEUTICAL used as a GLUCOSE replacement for metabolic imaging. Cancer treatment uses radiopharmaceuticals that are designed to go directly to the organ considered for treatment, for example rhodium (^{105}Rh) and rhenium-188, mostly used as beta emitters to inflict CELL death. In therapeutic applications, the success will hinge on the target to nontarget differentiation of uptake of the peptide or other molecular structure (see Figure N.64).

Figure N.64 (a) Illustration of the thyroid gland and (b) the treatment of thyroid cancer is one application of nuclear medicine.

Nuclear microscope

[general, nuclear] Force probe microscopy on ATOM scale (*also see* ATOMIC FORCE MICROSCOPE).

Nuclear models

[nuclear] Various models are available to describe the nuclear structure, based on energetic configuration or resulting from historical observations. Some of the models available are collective model, compound NUCLEUS model, direct reaction model, LIQUID-DROP MODEL, Rutherford model, and Bohr SHELL MODEL.

Nuclear reactor

[atomic, nuclear] Power-generating mechanism based on NUCLEAR FISSION or FUSION, creating steam to drive turbines that generate ELECTRICITY for general consumption. The general construction of a nuclear reactor has RODS of various composition suspended in a LIQUID. The fuel rods form the principle nuclear reaction, such as uranium-235 in a FISSION reactor; balanced by control rods that can partially capture the emissions driving the nuclear reaction, hence controlling the rate of the reaction, as well as the liquid itself which is known as the MODERATOR and often consists of "HEAVY WATER," a mixture of bound oxygen molecules tied to deuterium or tritium, replacing the standard hydrogen in water. The bath is surrounded by a concrete shield for absorption of stray emissions. In the nuclear conversion process the base for the fuel is obtained from various locations, each with specific grade of purity and contamination. The mined components will require processing, that is, enrichment, before it can be used in a nuclear reactor. An additional step in the preparations before use in the power station is the fabrication of the fuel rods from the enriched uranium, for instance. The steam GENERATOR is separated from the reactor vessel to avoid contamination, and relies on a heat exchanger to transfer the heat from the REACTOR to the steam generator. The steam is maintained in a closed circuit at pressures on the order of 0.5 mPa or greater. The steam is lead through the TURBINE from where it is cooled by a CONDENSER that vents to the outside by means of the cooling towers. A different type of nuclear reactor is the breeder reactor, which produces fuel for fission in parallel with generating power, producing plutonium-239 from uranium-238. Spent fuel will remain radioactive for several hundred years, up to in excess of a thousand years (depending on the accepted cut-off emission threshold), and requires an elaborate system of waste-management. Because of the high ENERGY radiation produced during the DECAY mechanism, nuclear power plants have a high risk associated with their operation. The first fission reactor was made operational in 1951 near Arco, Idaho. Several accidents with nuclear reactors have resulted in

long-term damage to the area in which the reactor was placed, for instance, Three-mile Island in Dauphin County, Pennsylvania (1979); Chernobyl in the former USSR, now Russia (1986), and the Fukushima Daiichi plant in Okuma and Futaba, Japan (2011). Additional accidents have involved the unplanned release of radioactive steam into the ATMOSPHERE and RADIATION leaks through cracks in the shielding concrete WALL of the reactor. An example of a natural FUSION REACTOR is the Sun, additional artificial fusion nuclear power plants have been created based on the tokamak principle. The first tokamak base fusion reactor was build and operated in Novosibirsk in 1968 (see [Figure N.65](#)).

Figure N.65 Nuclear power plant reactor design. (Courtesy of General Electric Corporation [GE], Fairfield, CT.)

Nucleation

[fluid dynamics, general, mechanics] Process of BUBBLE formation, followed by collapse (CAVITATION). Formation of temporary voids in a LIQUID resulting from thermal agitation (i.e., boiling or PLASMA formation [the latter in the case of both solid and liquid media]), growing from MICROSCOPIC to MACROSCOPIC proportions (*see* CAVITATION) (*see* Figure N.66).

Figure N.66 (a) Progress of bubble formation and (b) nucleation.

Nucleon

[nuclear] The common name for the constituent parts of the NUCLEUS. At present applied to protons and neutrons, but will include any other PARTICLE that is found to exist in the nucleus (see Figure N.67).

Figure N.67 Chart of nuclides. Nucleon pattern, proton versus neutron assembly.

Nucleon configuration

[atomic, nuclear] The NUCLEUS consists of protons identified by the atomic number Z and neutrons indicated in quantity by N . The following configurations for the nuclear make-up can be recognized: even proton-even neutron (even-even), odd proton-odd neutron (odd-odd), odd proton-even neutron (odd-even), even proton-odd neutron (even-odd). The even-even configuration has an even mass number ($Z + N = A$); note that the electron mass ($m_e = 0.0005446623 \text{ amu} = 9.10938188 \times 10^{-31} \text{ kg}$) is negligible compared to the NEUTRON mass $m_n = 1.0086649156 \text{ amu} = 1.6749 \times 10^{-27} \text{ kg}$ and proton mass $m_p = 1.00727638 \text{ amu} = 1.6726 \times 10^{-27} \text{ kg}$. The even-even configuration is the largest population of ELEMENTS with 148 stable nuclides with an additional 21 long-lived radio-active nuclides, the odd-odd group contributed only 5 stable atomic structures and 4 long-lived primordial nuclear ISOMERS, the odd-even configuration has 48 stable nucleons with an additional 5 long-lived nuclides, and the even-odd nuclei total 53 stable and 3 long-lived isotopes. All even-even nuclei have a base total nuclear SPIN of $s = 0$ in GROUND STATE, the odd-odd nuclides have integer spin; however, none has spin zero. All remaining nuclides with odd mass-number are classified as fermions, meaning that the total spin is half-integer, and have an array of spin number orientations.

Nucleus

[nuclear] The heavy central part of an ATOM in which most of the mass and the total positive ELECTRIC CHARGE are concentrated, greater than 99.975%. The charge of the NUCLEUS, an integral multiple Z of the charge of the PROTON, is the essential factor that distinguishes one ELEMENT from another. Z is the atomic number. The net POSITIVE CHARGE of the nucleus forms the attractive mechanism for orbiting electrons defined by the coulomb force.

Nuclide

[nuclear] General term referring to all nuclear species and isotopes, both stable (known so far 275) and unstable (approximately 500), of the chemical ELEMENTS known and listed in the PERIODIC TABLE OF ELEMENTS (see NUCLEON).

Numeric evaluation

[acoustics, computational, general, optics] Mathematical analysis based on function association, tying parameters together. When the mathematical correlation becomes too complex, the function may be solved numerically by insertion of incremental steps. One specific example of a NUMERICAL analysis is in the propagation of ELECTROMAGNETIC RADIATION through SCATTERING media, as applied to galactic dust and in biomedical applications for the EQUATION OF RADIATIVE TRANSFER. Additional numerical analyses are common in FLUID DYNAMICS due to the complex boundary conditions of a system of interest, providing a three-dimensional result that is location specific and varies with time.

Numerical

[computational, fluid dynamics, general, optics] The mathematical approach for solving equations by means of taking numerical incremental steps and solving step-wise with numerical data point solutions that are logged and graphically represented. An analytical solution stands in contrast to a numerical approach, both providing an equation all the same.

Numerical aperture

[general, optics] (NA) introduced by ERNST ABBE (1840–1905) as $NA = n \sin \theta$, with θ is the maximum half—solid-angle of the “hypothetical” cone defined at the surface of an optical device (e.g., LENS, fiber-optic face) within which light can exit or enter the optical device and n is the INDEX OF REFRACTION of the medium in which the lens is placed. Parameter for optical devices that describes the relationship between the maximum APERTURE to the focal length of, for instance, a compound lens system. The numerical aperture is defined by half the acceptance ANGLE (θ) of the device and the index of refraction of the medium (n) through which the ELECTROMAGNETIC RADIATION travels as $NA = n \sin \theta$. Hence, the numerical aperture can be increased by placing a drop of OIL between the specimen on a MICROSCOPE slide and the objective of the microscope. The numerical aperture is an indication of the light gathering capability of an optical system, the larger the better (see Figure N.68).

Figure N.68 Numerical aperture.

Numerical fluid mechanics

[computational, fluid dynamics] Computational techniques for solving Navier–Stokes equations as well as finite ELEMENT techniques for three-dimensional solutions. The finite element methods will generate a grid pattern that has variable RESOLUTION depending on the geometric and anticipated FLUID DYNAMICS complexity within a certain volume. The computational aspects are geared to finite differences approximations for elliptic, parabolic, and hyperbolic equations. Often, the NUMERICAL approach uses Fourier decomposition and requires error analysis to establish the validity of the SOLUTION and within what domain. In particular, the use of numerical analysis applies to turbulent flow characteristics and boundary conditions. The time-resolved assessment is also very useful for flow development and time perturbation analysis (*also see COMPUTATIONAL FLUID DYNAMICS*).

Nusselt (Nußelt), Ernst Kraft Wilhelm (1882–1957)

[biomedical, fluid dynamics, thermodynamics] An engineer and scientist from Germany. Nusselt developed the dimensional HEAT TRANSFER analysis (see Figure N.69).

Figure N.69 Ernst Kraft Wilhelm Nusselt (Nußelt) (1882–1957). (Courtesy of Technische Universität (TU) Dresden, Dresden, Germany.)

N

Nusselt number ($Nu = h_i L / \kappa$)

[fluid dynamics, thermodynamics] Dimensionless number identifying the temperature gradient at a surface, for instance, under FLOW or condensation; it was introduced by ERNST KRAFT WILHELM NUSSALT (Nußelt) (1882–1957); this surface phenomenon relates to BOUNDARY LAYER or condensate film respectively. (Note that for condensate film, $Nu = \bar{h}_i L / \kappa = c \left[(\rho_\ell g (\rho_\ell - \rho_v) h_{fg} L^3) / (\eta_{\text{molec}} \kappa_l (T_{\text{sat}} - T_w)) \right]$, where L is the characteristic dimension of the phenomenon, κ is the THERMAL CONDUCTIVITY, and $\bar{h}_i$ is the HEAT TRANSFER coefficient, $\bar{h}_i$ is the average heat transfer coefficient for condensation of a film respectively, ρ_ℓ is the density of the VAPOR, ρ_v is the density of the vapor, g is the GRAVITATIONAL ACCELERATION, h_{fg} is the LATENT HEAT of vaporization, η_{molec} is the molecular viscosity, κ_l is the thermal conductivity of the LIQUID, T_{sat} is the SATURATION temperature of the vapor, T_{sat} is the surface temperature, and constant c is dimensionless and accounts for size and shape. From this, it becomes evident that for smaller bodies, (characteristic dimension small) the heat transfer coefficient is larger than for large bodies. The definition of the Nusselt number is the transport of THERMAL ENERGY ratio between that under forced convection to that of conduction. As with any dimensionless number, the role is to reduce the quantity of independent variables.

Nutation

[astrophysics/astronomy, biomedical, mechanics] Rocking, oscillating, swaying, or bobbing MOTION of the axis of rotation of a predominantly axially symmetric object. This MOTION may pertain to the earth's rotation, a GYROSCOPE. Additionally, certain plants have slow or fast nutation resulting from unequal rate of growth at respective different sides (sunflowers orient themselves toward the Sun as the day passes). Other examples are the sensitivity of certain plants to temperature, such as the tulip and the crocus. The crocus can distinguish a temperature change of 0.5°C and will change its orientation/inclination in response to a

temperature change of 20°C within 2 min. In biology, there is the pivotal motion of the sacrum (gyration, in reference to the dance moves by Elvis Presley [1935–1977]), which is a large, triangular bone at the base where the spine meets the pelvic bone (*also see* PRECESSION) (see Figure N.70).

Figure N.70 Nutation spinning top stays erect, but “wobbles” about the equilibrium.

Nuttall, John Mitchell (1890–1958)

[atomic, nuclear] A physicist from Great Britain. John Nuttall discovered the regularities of DECAY rates for even-even nuclei (even number of protons [Z]; even number of neutrons [N]) and introduced the decay constant. He has been a collaborator with Hans Geiger on the detection of RADIATION. The collaborative efforts resulted in the GEIGER–NUTTALL LAW of RADIOACTIVE DECAY: $\log \lambda = a + b \log r_{\text{range}}$, where λ is the decay rate, r_{range} is the range of radiation in AIR, a is a material parameter, and b is a constant.

Nylon

[biomedical, chemistry] It is a synthetic POLYMER. Nylon is a versatile material used in many consumer and industrial applications as well as in biomedical use for prosthetic construction and reinforcement, also used as suture material and sewing wire. Nylon is a diverse family of products that were initiated at DuPont in 1935 by Wallace Carothers (1896–1937). Nylon as a generic definition is a polyamide of repeating chemical units that are linked by amide bonds. Nylon is a copolymer formed through condensation of diamine and a dicarboxylic ACID, in equal parts, forming the amide chains. Nylon was used initially in broom brushes and shortly thereafter in lady’s stockings (“nylons,” introduced in the 1940s). Nylon can withstand high temperatures and as a solid sheet can be press-molded into most any shape and has a MELTING POINT of

256°C. Nylon has a high tensile strength and is used as rope for a broad range of applications, including hoisting heavy equipment (see [Figure N.71](#)).

Figure N.71 (a–f) Illustrations of the use of Nylon.

Nyquist, Harry Theodor ("Nyqvist") (1889–1976)

[computational, thermodynamics] A Swedish electrical engineer and physicist. Nyqvist worked for AT&T and Bell laboratories. In 1960, Nyquist received the IRE Medal of Honor from the Institute of Radio Engineers, for his involvement in the description of "fundamental contributions to a quantitative

understanding of thermal NOISE, data transmission and negative feedback.” His collaborative work with CLAUDE ELWOOD SHANNON (1916–2001) led the foundations for information theory and SIGNAL sampling principles, additionally his work with Herbert Eugene Ives (1882–1953) formed the roots for feedback control theory (see [Figure N.72](#)).

Figure N.72 Harry Theodor Nyquist (“Nyqvist”) (1889–1976). (Courtesy of IEEE.)

Nyquist frequency

[computational] The highest frequency component that can be distinguished at half the frequency at which data acquisition is performed. The Nyquist frequency provides a discrete data array as a function of time. This concept was proposed by HARRY THEODOR NYQUIST (1889–1976).

Nyquist rate

[computational] The minimum sampling frequency that needs to be applied to obtain the frequency resolution of the highest rate of change in an observed phenomenon, obtained at a RESOLUTION that is half the Nyquist rate sampling frequency, as a continuous-time signal. Introduced by HARRY THEODOR NYQUIST (1889–1976). Sampling at lower rates (i.e., undersampling) may result in ALIASING, where DRIFT between separate signals is not captured as individual data streams; this may be linked to two separate signal functions (separate sources) that produce similar data streams, which can be out of PHASE. Oversampling will cost in processing time and can result in missed data points or introduce NOISE.

Nyquist–Shannon sampling theory

[computational] The SAMPLING rate for data acquisition for an observation will need to be at least twice the frequency of the phenomenon under observation in order to retrieve all frequency information imbedded in the events, and subsequently separate out individual events and factors driving the manifestation of physical parameters. This principle was introduced by HARRY THEODOR NYQUIST (1889–1976) and CLAUDE ELWOOD SHANNON (1916–2001). If an observation in time $f(t)$ is confined to a maximum

frequency of $v^* H_z$, the phenomenon is fully determined by a data array with time spacing of samples information at $(1/v^*)s$ intervals (*also see* **NYQUIST FREQUENCY**) (see [Figure N.73](#)).

Figure N.73 Mathematical mechanism of action used to interpolate the numeric sequence during signal sampling can be described by sinc functions.

Nystagmus

[biomedical, mechanics] The locking **MOTION** of the eyes on a target point during rotation of the body followed by a slow tracking when the observational limit is reached. The quick reflect of the **EYE** followed by slow deviation tracking is nystagmus. Nystagmus can consist of rotational, horizontal, or vertical motion. In humans, the irritation of the labyrinth of the **EAR** used for equilibrium can cause random eye motions; one aspect is the irrigation of the ear by cold water resulting in involuntary nystagmus. Nystagmus also provides a tool for the analysis of certain brain disorders. Additionally, nystagmus can be used to describe the uncontrollable motion of the eye as a clinical condition (“dancing eye,” affecting one in several thousand people) (see [Figure N.74](#)).

Figure N.74 Nystagmus.

Oak Ridge National Laboratory

[atomic, nuclear] Oak Ridge, Tennessee, was established in 1942 as a uranium enrichment production site for the MANHATTAN PROJECT. The city still hosts a major concentration of basic and applied research. The Oak Ridge National Laboratory and the University of Tennessee are combining their effort, supported by federal and state funding and a public research. The Oak Ridge National Laboratory is the largest US Department of Energy research facility, focusing on multifaceted and multidisciplinary science and technology research, managed by UT-Battelle, LLC (see [Figure O.1](#)).

Figure O.1 Oak Ridge National Laboratory. (Courtesy of the United States Department of Energy, Washington, DC.)

Obert, Edward F. (1910–1993)

[thermodynamics] A scientist and engineer from the United States. The work of Obert includes the published charts illustrating the “PRINCIPLE OF CORRESPONDING STATES” with L.C. Nelson in

1954, referring to the work of JOHANNES DIDERIK VAN DER WAALS (1837–1923), published in 1880 (see [Figure O.2](#)).

Figure O.2 Edward F. Obert (1910–1993) on right during the award of the Benjamin Smith Reynolds Award for outstanding contributions to the teaching of engineering students, May 4, 1973. (Courtesy of the University of Wisconsin-Madison College of Engineering, Madison, WI.)

Object wave

[general] Light incident on an object is diffracted, forming a collective WAVE front of scattered light that is subject to superposition generating a collective WAVEFRONT referred to as the “object wave” (see [Figure O.3](#)).

Figure O.3 Representation of the appearance of an object wave pattern.

Oblique angle scanning

[acoustics] Scanning of multilayered targets with ULTRASOUND, specifically using pulse-echo detection, yields reverberations that complicate the direct characterization of the composition of the medium. Under oblique ANGLE detection, the first order reverberant echoes are rejected, hence providing a more clearly

defined ultrasound SIGNAL with greater detail. Similar principles also apply in positron emission TOMOGRAPHY imaging. The oblique angle SCATTERING brings about considerable artifacts that interfere with proper IMAGE formation (see Figure O.4).

(a)

(b)

Figure O.4 (a) Oblique angle deflection providing characteristics about the structure and composition of a medium and objects within a medium. For instance, the mere visual recognition of the material (metal, plastic, ivory, or wood) in this optical scatter image of chess pieces as well as the identification of the isolated pawn. (b) Oblique detection angle for ultrasound imaging.

Oblique shock wave

[fluid dynamics] A SHOCK WAVE propagation traveling with inclination with respect to the incident upstream FLOW direction, unlike a normal shock. An oblique shock wave is generally formed at the tip (wedge) of an object in supersonic, compressible, flow. An example is the thermodynamic discontinuity at the nose of a plane approaching, and subsequently exceeding Mach velocity. The WAVE is at this point deflected at an corner angle (θ), diverting with respect to the streamlines: α , the oblique shock angle, conforming to: $\tan \theta = 2 \cot \alpha [(M_1^2 \sin^2 \alpha - 1) / M_1^2 (\gamma_{hc} + \cos 2\alpha + 2)]$, where M_1 represents the MACH NUMBER, and γ_{hc} the heat capacity ratio. The MACH WAVE itself is only an infinitesimally weak shock wave. The coalescing of a

multitude of Mach waves originates an actual oblique shock wave, similar to the normal shock wave. The flow direction of the oblique shock wave is tangential to the surface of the disturbance. Similar principles also apply to NOZZLE flow (see [Figure O.5](#)).

(a)

(b)

Figure O.5 (a) Principle of oblique shock wave and (b) low frequency shockwaves for joint therapy.

Occhialini, Giuseppe ("Beppo") Paolo Stanislao (1907–1993)

[astrophysics/astronomy, nuclear, thermodynamics] A geophysicist from Italy involved in the identification of COSMIC RAYS, concerning charge and ENERGY. He is a close collaborator with PATRICK BLACKETT (1897–1974). Giuseppe Occhialini also contributed to the discovery of the pi-meson (PION) in 1947, while the other associates of the research team that all received the Nobel Prize in Physics are César (Cesare) MANSUETO GIULIO LATTES (1924–2005) and CECIL FRANK POWELL (1903–1969) (see [Figure O.6](#)).

Figure O.6 Giuseppe ("Beppo") Paolo Stanislao Occhialini (1907–1993) in 1925. (Courtesy of the Università degli Studi di Milano-Bicocca, Milan, Italy.)

Oceanography

[energy, fluid dynamics, general, geophysics] A field of PHYSICS dealing with physical phenomena in the LIQUID part of EARTH'S ATMOSPHERE directly related to the FLOW and PHASE transitions of the oceans and large and small bodies of water, also referred to as "MARINE GEOPHYSICS" (*see* HYDROLOGY) (*see* Figure O.7).

(a)

(b)

Figure O.7 (a) Geographic description of the Antarctic Ocean water composition and (b) 1872 hypothetical description of a cross section of the Atlantic Ocean, limited due to incomplete information as a result of unavailability of instrumentation.

Octane number

[chemical, mechanics] A fossil fuel standard that represents the reciprocal of the PROBABILITY that an ENGINE will have incomplete combustion as a result of spark ignition in a four-stroke engine. An octane number of 100 represents perfect combustion and is rated based on isooctane (2,2,4-trimethylpentane,

C_8H_{18}). The number will depend on the compression ratio of the piston/cylinder configuration. The octane number of a fuel is determined in the “cooperative fuel research knock-test engine,” which has a variable compression ratio (see [Figure O.8](#)).

Figure O.8 Gasoline pump with octane numbers for the different grades of fuel.

Octave

[acoustics] Particular to music, the interval between one PITCH and another with double or half the respective frequency. The concept dates as far back as PYTHAGORAS (c. 570–490 BC). Musical notes that are one or several octaves apart are represented by the same letter symbol (C, D, E, etc.). In ELECTROMAGNETIC THEORY, the same applies; the best example is the visual response of the HUMAN EYE is approximately one octave: 325–650 nm, within certain luminescent boundaries. Octave equivalence denotes the fact that certain resonant frequencies share many of the same overtones. Octave equivalence refers to the format of the affinity of tones, synonymous to similarity. A concept referred to as “octave equivalence” has been observed in human infants and rats. This refers to the sensory octave affinity, which is based on commonality of multiple pitches in harmonic complex tones (see [Figure O.9](#)).

Figure O.9 Outline of piano keys over the spectral band of an octave.

Octave stretching

[acoustics, computational] The fact that octaves derived historically are not perfect 2:1 ratios. Octave stretch of tones of musical instruments was described by John F. Corso (1920–2013) in 1954.

Ohm, Georg Simon (1789–1854)

[biomedical, electronics, general, thermodynamics] A physicist and scientist from the Holy Roman Empire or Prussia, Germany. The scientific deductions of Georg Ohm while performing experimental observations with the electrochemical cell, GALVANOMETER from ALESSANDRO VOLTA (1745–1827), made him derive the relationship between current and applied electrical potential (voltage) and the associated electrical RESISTANCE known as “OHM’S LAW” (see [Figure O.10](#)).

Figure O.10 Georg Simon Ohm (1789–1854).

Ohm meters

[general] A portable instrument for measuring a broad range of values for electrical resistance pertaining to CONDUCTOR, SEMICONDUCTORS, and insulating devices. The ohmmeter is an active device, working based on an applied constant current, the RESISTANCE between two points can be derived using OHM’S LAW. Care needs to be taken that the contact resistance is negligible, between the measuring probe and the device (see [Figure O.11](#)).

Figure O.11 Ohm meter, part of a multi-meter.

Ohm's law

[biomedical, electronics] A relationship derived by GEORG SIMON OHM (1789–1854) describing the current through a RESISTOR (R) resulting from an applied electrical potential across the resistor of V is defined by $I = V/R$ (see Figure O.13).

Figure O.13 Ohm's law and associated definitions.

Ohmic circuit element

[general] Electronic device that maintains a linear relationship between the applied potential and the current FLOW (see Figure O.12).

Figure O.12 Drawing of ohmic circuit diagram.

Ohnesorge number ($Z = \eta / (c_z \sqrt{\rho L \sigma})$)

[fluid dynamics, mechanics] A dimensionless number indicating the ratio of the net viscous force to the equalized inertial and surface forces (e.g., SURFACE TENSION OR FRICTION), which is expressed as the square root of the product of the latter two forces, with η the VISCOSITY, c_z dimensionless constant, ρ the density of the LIQUID, L the characteristic dimension of the phenomenon, and σ the surface tension. The Ohnesorge number is primarily used in the classification of momentum transfer, for instance, in ATOMIZATION.

Oil

[chemical, fluid dynamics, mechanics] Fossil residue that has many chemical applications, ranging from combustible fuel to lubricants and the production of PLASTICS. Oil is neutral in charge and nonpolar. The substance is a viscous LIQUID that is hydrophobic as well as lipophilic, OIL will float on water and mix with fatty substances. Crude oil or petroleum is the most recognized base material; however, plant and seed extracts are also referred to as “oils.” Next to petrochemical crude oil, we know mineral oil and sunflower oil as well as other plant products and animal oils. Chemically, oils are liquids with a high carbon and hydrogen content. Oils have applications in painting, cooking, cosmetics, LUBRICATION, base ELEMENTS for generation of chemical components, and fuels, and have attributes that make them effective HEAT TRANSFER media (e.g., high thermal conductivity, high flash point, and high vapor point). When a thin layer of oil covers a large surface of water, the mechanical properties of the water are directly affected as expressed by the modifications to the WAVE phenomena. The oil film results in a reduction of the AMPLITUDE of the water waves and also affects the Fourier spectrum of the wave phenomena, eliminating higher order frequencies (see [Figure O.14](#)).

(a)

(b)

Figure O.14 (a) Oil rig (oil platform) used for drilling for oil and (b) olive oil.

Oil-drop experiment

[atomic, nuclear] An experiment devised by ROBERT ANDREWS MILLIKAN (1868–1953) to determine the elementary ELECTRIC CHARGE (see **MILLIKAN OIL-DROP EXPERIMENT**).

Oil-film method

[fluid dynamics] Mechanism to provide a fast and simple approach to help validate computational FLUID DYNAMICS numerical simulations of fluid flow. Colored OIL injected in or floating on top of a fluid-dynamics process will provide a visual display of the FLOW processes, and boundary phenomena.

Old quantum theory

[general, quantum] Early theoretical results in QUANTUM MECHANICS from 1900 to 1925, based on Bohr–Sommerfeld quantization, which predate modern quantum mechanics. The original principles of QUANTUM THEORY were introduced in 1905 by ALBERT EINSTEIN (1879–1955), describing the quantum theory of light. The principles of the old quantum theory rely on the fact that MOTION in an atomic system is discrete and can be quantized. Such as system generally obeys classical mechanics with the exception that not every motion is allowed; only the motions that obey the old quantum condition are allowed: $\oint_{H(p,q)=E} p_i dq_i = n_i h$, where $H(p, q) = E$ is the Hamiltonian of the motion, p_i denotes the momentum values of the system and the q_i denotes the corresponding coordinates, n_i is the respective quantum numbers and $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ is PLANCK'S CONSTANT. The integral is taken over one period of motion, taken at constant ENERGY, which is defined by the Hamiltonian.

Oncotic pressure

[biomedical] A specific form of OSMOTIC PRESSURE under the Starling principle: COLLOID OSMOTIC PRESSURE, partial pressure (Π) resulting from the large protein molecular solution in BLOOD or biological PLASMA (note that the protein cannot transport through the MEMBRANE of the vessel wall): $\Pi = -(RT/V) \ln(x_{\text{sol}}) \Rightarrow iMRT$, where $R = 8.3144621(75) \text{ J/Kmol}$ is the GAS constant, T is the TEMPERATURE, V is the VOLUME, $x_{\text{sol}}^{\text{ideal}}$ is the fractional MOLE solute concentration, i is the VAN'T HOFF FACTOR, and M is the molarity (see [Figure O.15](#)).

Figure O.15 Oncotic pressure resulting from interstitial fluid solution concentration.

One-dimensional compressible flow

[fluid dynamics] Many of the compressible flows can be modeled as flows through a PIPE, duct or a stream tube for which cross-sectional area changes with relatively small gradual increments in the FLOW direction, relative to the flow velocity. For one-dimensional approximation, there can be no flow components perpendicular to the streamline. Generally, the flow will be steady state. The laws of CONSERVATION OF MASS and momentum apply. The flow conditions under negligible viscous forces are described by the Euler equation: $-(dP/\rho) = v dv$, where P is the pressure, ρ the density, and v the flow velocity. The CONSERVATION OF ENERGY provides the condition that the net change in enthalpy ($H = U + PV$, where U is the internal ENERGY, P is the pressure of the system, and V is the volume) and kinetic energy (E_{kin}) must equal the heat transferred into the control volume and the work done by the FLUID (per unit mass), neglecting work yields: $c_p T + (v^2/2) + dq = c_p (T + dT) + [(v + dv)^2/2]$, where T is the system temperature, c_p is the SPECIFIC HEAT under constant pressure and $q = \dot{Q}/\dot{m}$, where $\dot{Q}$ is the rate of flow and $\dot{m}$ is the change in mass over time.

One-dimensional flow

[fluid dynamics] For incompressible flow, the conditions are very similar to the compressible flow, with the exception that the Euler equation reduces to BERNOULLI'S EQUATION: $(v^2/2) + (P/\rho) = \text{constant}$, where P is the pressure, ρ is the density, and v is the FLOW velocity.

Onnes, Heike Kamerlingh (1853–1926)

[atomic, general, material science, solid-state, thermodynamics] See **KAMERLINGH ONNES, HEIKE**.

A physicist from the Netherlands involved with CRYOGENIC research and the effects of cold temperatures on materials, specifically near the ABSOLUTE ZERO (0 K). Heike Kamerlingh Onnes established the LIQUEFACTION temperature of Helium (${}^4_2\text{He}$) to be at 4.2 K. Kamerlingh Onnes received the Nobel Prize for Physics in 1913 for his cryogenic work. Dr. Kamerlingh Onnes was a colleague and research associate of JOHANNES DIDERIK VAN DER WAALS (1837–1923) during his appointment at the Delft University of Technology. The work of Kamerlingh Onnes provided a great deal of insight into the conditions near absolute zero, which he approached to close degree. His work on cryogenic cooling and the effect it has on materials also offered a new concept: SUPERCONDUCTIVITY.

Onsager reciprocal relations

[thermodynamics] In thermodynamic systems, the Onsager reciprocal relations are used to express the equality of particular ratios between forces and flows that are not specifically in equilibrium; however, local equilibrium may exist under strict boundary conditions. It was introduced by the Norwegian scientist Lars Onsager (1903–1976) in 1931.

Opaque

[general, solid-state] Not transparent, material property.

Open channel

[fluid dynamics] Flow conditions for a system consisting of a conduit with a free surface. A free surface is where a FLUID has zero parallel shear stress and is simultaneously subject to constant perpendicular normal stress. Examples of free surface are the boundary between two homogenous fluids, such as the liquid–water interface with the AIR in the Earth's ATMOSPHERE. This applies, for instance, to channel FLOW (see [Figure O.16](#)).

Figure O.16 Open channel.

Open channel, Bazin equation

[fluid dynamics] Equation for deriving the average flow velocity of water flowing in an OPEN CHANNEL, proposed by Henry E. Bazin (1829–1917) in 1897 (finalized after his death by his assistant Henri P. G. Darcy [1803–1858]). There is a close correlation with the CHÉZY'S FORMULA for flow in an open channel, relying on the Chézy discharge coefficient ($C_{\text{Chézy}}$), with relations to the FLOW configurations defined by the hydraulic radius (r_h) and a channel roughness coefficient (k_s), expressed as $C_{\text{Chézy}} = 157.6 / [1 + (k_s / (1/2)r_h)]$. This yields the average velocity (v_{avg}) as $v_{\text{avg}} = C_{\text{Chézy}} \sqrt{i_{\text{slope}} r_h}$, where i_{slope} is the slope of the bedding of the flow system (e.g., the bottom of the river) (see [Figure O.17](#)).

Figure O.17 Open channel flow, wide canal flowing out into the North Sea.

Open channel, Chézy's formula

[fluid dynamics] An empirical formula designed by the French HYDRAULICS engineer ANTOINE DE CHÉZY (1718–1798) in 1775 that relates river flow (Q) to the dimensions of the channel (i.e., the hydraulic radius, r_h) and slope of the water surface (s_{surface}) as $Q = AC_{\text{Chézy}} \sqrt{r_h s_{\text{surface}}}$, where A is the cross-sectional area of the river, and $C_{\text{Chézy}} = 157.6 / \{1 + [k_1 / (r(1/2))]\}$ is the Chézy discharge coefficient.

Open channel, Ganguillet–Kutter equation

[fluid dynamics] An empirical formula designed by the Swiss HYDRAULICS engineers Emile Oscar Ganguillet (1818–1894) and Wilhelm Ruldoph Kutter (1818–1888) in 1869 that relates average river flow velocity (v) to the dimensions of the channel (i.e., the hydraulic radius, r_h) and slope of the water surface (s_{surface} , representing the ENERGY drop) as

$$v = \left\{ \frac{(a + (b/n_K) + (P/s_{\text{surface}}))}{\left[1 + (n_K/\sqrt{r_h})(a + (P/s_{\text{surface}}))\right]} \right\} \sqrt{r_h s_{\text{surface}}},$$

where n_K is the Kutter roughness factor, which is generally between 0.01 and 0.035 for the usual channel bottom surfaces; the value of Kutter's C , to be used with Chézy's formula, ranged from 22 to 220, where $a \sim 41.66$ for uniform channel and $b \sim 1.811$ for uniform channel are coefficients based on the work of Henri E. Bazin (1829–1917) and P represents the hydrostatic pressure. For values of $s_{\text{surface}} > 0.0005$ the term P/s_{surface} can generally be neglected.

Open channel, hydraulic mean depth

[fluid dynamics] The ratio of the cross-sectional area to the surface width. Channels can have many different contour configurations based on the methods in which the channel was dug-out, primarily a V-shape is found (such as the Suez Canal), but over time the shape can change. Other digging mechanism require a more rectangular shape, such as the Panama Canal (see [Figure O.18](#)).

Figure O.18 Locks for the Panama Canal.

Open channel, Manning equation

[fluid dynamics] An empirical formula derived by the Irish engineer ROBERT MANNING (1816–1897) in 1851, that relates river flow (Q) to the dimensions of the channel (i.e., hydraulic radius: r_h) and slope of the water surface (s_{surface}) $Q = (C_{\text{Chézy}}/n) \mathcal{A} r_h^{2/3} i_{\text{slope}}^{1/2}$, where n is Manning's coefficient (accounting for FLOW bed roughness), $C_{\text{Chézy}} = 157.6 / \{1 + [k_1 / (r(1/2))]\}$ is the Chézy discharge coefficient, i_{slope} is the slope of the bedding of the flow system (e.g., the bottom of the river), $\mathcal{A}$ is the cross-sectional area of the river; which translates to an average velocity: $v_{\text{avg}} = (C/n) r_h^{2/3} i_{\text{slope}}^{1/2}$.

Open cycle

[fluid dynamics, thermodynamics] The concept of the open cycle relates to thermodynamic processes but has no physical thermodynamic meaning. The concept refers to the external ENERGY supply to, for instance, an ENGINE in the form of fossil fuel and that the remaining, unconverted portion of energy embedded in the spent combustion mixture, is expelled as exhaust to the environment. THERMODYNAMICS cycles can be divided in two categories: power cycles and heat-pump cycles. The POWER CYCLE produces power output while the heat-pump cycle has a net power consumption. GAS turbines fall under the power cycle and have an open cycle, representing the intake of fresh AIR and the exhaust. Other open-cycle dives are combustion engines. This is different from refrigeration, which is a closed cycle, or cyclic system (see Figure O.19).

Figure O.19 Example of an open-cycle process: Heat pump cycle diagram.

Open Joule–Brayton cycle

[thermodynamics] A thermodynamic process of combustion, heat ENGINE, or boiler that is per definition open, involving intake and exhaust. The Joule–Brayton cycle is a constant-pressure cycle that defines the operation of the GAS turbine engine (e.g., JET engine and electric power generation). It is named after American engineer George Brayton (1830–1892), although it was originally proposed and patented by English engineer John Barber (1734–1801) in 1791. The involvement of English physicist JAMES PRESCOTT JOULE (1818–1889) added his name to the process. The Joule–Brayton cycle applies to gas turbines only when both the compression and EXPANSION processes take place in rotating process (machine). The Joule–Brayton cycle is a sequence of an ISENTROPIC compression and isentropic turbine. The useful power generated by the TURBINE is the difference between the compression ($P_T = mc_p T_i (1 - (1/\delta)^{(\kappa-1)/\kappa})$, where κ is the SPECIFIC HEAT ratio, δ is the pressure drop at the outlet, m is the mass of the combustible, c_p is the specific heat under constant pressure, and T is the temperature) and turbine ($P_T = m\Delta h = mc_p \Delta T$, where h the specific enthalpy): $P = P_T - P_C$, also known as either “Brayton cycle” or “Joule cycle.”

Open MRI

[biomedical, imaging] Magnetic RESONANCE imaging system that has a configuration with large bore access, in contrast to the traditional MRI machines that have a narrow cylinder through which the patient is transported on a sliding table during the image-slicing process. Open MRI uses permanent magnets and have lower NOISE than the traditional MRI (see [Figure O.20](#)).

Figure O.20 Comparison of open-design MRI machine versus the conventional closed MRI.

Operational amplifier (OpAmp)

[electronics] A differential input high-gain electronic voltage amplifier, using DC coupling, with usually a single-ended output. By configuring the power supply and the termination impedance ratio across the specific POLES, an output potential can be generated that is hundreds of thousands of times larger than the POTENTIAL DIFFERENCE between the input terminals, the gain, while simultaneously maximizing the signal-to-noise ratio. In contrast, a simple resistor, TRANSISTOR, CAPACITOR, and INDUCTOR circuit can generate amplification, but the NOISE follows suit to the SIGNAL. OpAmps were initially used in analog computers. OpAmps can perform basic mathematical operations, such as multiply, differentiate, integrate, and in turn provide filtering opportunities. The mathematical operations are selected based on the configuration of the electronic peripheral components, a capacitor will provide the basic tools for integration. OpAmps are some of the most widely used electronic devices. OpAmps are found in various and vast amounts of consumer devices as well as industrial and scientific devices. OpAmps are generally based on semiconductor materials; however, George A. Philbrick (1913–1974) introduced a VACUUM tube OpAmp in 1948. Following the birth of the transistor in 1947, the first discrete integrated circuit (IC) OpAmp was introduced in 1961 (see [Figure O.21](#)).

Figure O.21 Diagram of operational amplifier.

Ophthalmology

[biomedical] Medical specialty that focuses on all aspects of the **EYE**, including but not limited to the **ANATOMY**, **PHYSIOLOGY**, and diseases of the eye. This branch of **MEDICINE** provides support for restoration or enhancement of **VISUAL ACUITY**. The specific anatomical components of the eye of interest are the **LENS** shape and functionality, the **RETINA**, signal communications (e.g., optic nerve), and the pathology of the lens, such as cataract, next to diseases to the optic nerve such as glaucoma (see [Figure O.22](#)).

(a)

(b)

Figure O.22 (a,b) Ophthalmologic eye exam.

Oppenheimer, Julius Robert (1904–1967)

[energy, general, nuclear, quantum] A theoretical physicist from the United States. President Roosevelt established the **MANHATTAN PROJECT** in 1941 and appointed Robert Oppenheimer as director in June 1942. The resulting first **ATOMIC BOMB** was detonated in new Mexico under his guidance on July 16, 1945, followed by two atomic bomb drops on Japan in July and August. Oppenheimer was one of the first scientist to predict the existence of **ANTIMATTER** based on theoretical analysis (see [Figure O.23](#)).

Figure O.23 Julius Robert Oppenheimer (1904–1967). (Courtesy of the Los Alamos National Laboratory, Los Alamos, NM, in 1943.)

Optical activity

[biomedical, chemical, optics] Rotation of polarization ANGLE of ELECTROMAGNETIC RADIATION induced by large complex molecules (chiral molecule), first observed in liquids and gases by JEAN-BAPTISTE BIOT (1774–1862). Two kinds of rotation can be distinguished: dextrorotary (clockwise rotation) designated as (+) and levorotary (rotate counterclockwise) designated as (–). Dextrose will generally rotate the polarized light clockwise, whereas fructose is a levorotary solution. Naturally occurring in milk, dextro-lactic ACID is a food, whereas artificially produced laevo-lactic acid is a poison (in actuality, left-turning lactic acid does occur in natural form however in extremely small percentage). The rotation of linearly polarized light by solid media was first observed by French physicist FRANÇOIS JEAN DOMINIQUE ARAGO (1786–1853) in 1811 in QUARTZ (see [Figure O.24](#)).

Figure O.24 Optical activity, such as would be experienced with glucose solution.

Optical attenuation screening for concentration

[biomedical, imaging, optics] Optical attenuation imaging method for determination of molecular separation while applying the ULTRACENTRIFUGE principle. The chromophores in the SOLUTE will absorb the incident ULTRAVIOLET or visible light and the density of chromophores is a direct indication of concentration due to the symmetric outline of the sample cell/ampule. The concentration is plotted as a function of location in the vial (also *see* CHROMATOGRAPHY and GAS CHROMATOGRAPH) (see [Figure O.25](#)).

Figure O.25 Chromatography spectral representation of chemical composition for DNA (deoxyribonucleic acid).

Optical biosensor

[biomedical, optics] Biometric sensors that rely on optical interrogation the determination of physiological parameters. One specific example is the attenuation determination of a minimum of two wavelengths for

BLOOD oxygen saturation in the application pulse oximetry. In pulse oximetry, the use of additional wave-lengths can eliminate errors resulting from biological variability in blood or surrounding tissues. Additionally, use of OPTICAL ACTIVITY has been applied to the determination of blood GLUCOSE levels with respect to diabetic patients, measured in the EYE (*also see* PULSE OXIMETRY) (see [Figure O.26](#)).

(a)

(b)

(c)

Figure O.26 (a) Optical biosensor using the back-scattered light to gain information about spectral signatures of chemical constituents (e.g., pulse oximetry [b]) and periodically changing events such as blood flow associated with heart pump rate (i.e., heart rate [c]).

Optical coherence tomography

[imaging, optics] Optical scanning imaging technique using interferometry to selectively collect light from axial locations at various depths from the surface used for tomographic IMAGE reconstruction. The general concept of optical coherence tomography (OCT) is very similar to B-SCAN ultrasound in the fact that point-by-point “intensity” data is collected for within a three-dimensional structure. The imaging principles of OCT rely on scanning the device across the surface of the volume of interest, without actually requiring

contact, as well as probing the surface location by changing the boundary conditions for the scanning device by optical and mechanical means. A two- or three-dimensional image reconstruction follows after all the required data points within the medium under investigation are collected, stored in a location specific matrix and processed for specific electromagnetic features contained in the optical signal. The main electromagnetic features are AMPLITUDE of the electric and MAGNETIC FIELD, the PHASE of the wave, the orientation of the electric field (POLARIZATION) as well as wavelength specific information. Since the wavelength of light is very small with respect to the scanning range, the phase of the WAVE becomes essential in isolating the relevant information in radiance with respect to the location of interest. Interference will provide a maximum intensity in the SIGNAL collected by a PHOTODETECTOR when the phase of the wave returning from an object under investigation matches the phase of a wave returning from a reference MIRROR in the balancing arm of the INTERFEROMETER. Consider a MICHELSON INTERFEROMETER, with a probing arm and reference arm that are the result of splitting the light from a source in two directions. Once the light returns from the probing arm and reference arm, it is recombined and the superposition principle applies to the two wave-phenomena that is measured by the photocell in the measurement arm. The INTERFERENCE signal in the measurement arm is maximal when the probing arm length matches the reference arm length. This interference pattern is repetitive in increments of the wavelength of the incident light from the source. For a MONOCHROMATIC LIGHT source, this makes the identification of the secondary source location inside the medium being investigated not uniquely defined, because the interference will occur at every wavelength DISTANCE with equal MAGNITUDE. When a broadband source is used, rather than a laser, the interference pattern of all the wavelengths in the spectral distribution of the source will need to coincide for maximal signal magnitude in the measurement arm. The use of a broadband optical source provides the critical aspect for depth resolved imaging under OCT. The advantage of optical imaging is that it can provide high RESOLUTION media-interrogating imaging (better than X-RAY, magnetic RESONANCE imaging, or ULTRASOUND) and it can be performed in situ using hand-held devices, specifically under in vivo conditions for biological imaging. The use of optical imaging also has no concerns for side effects, and light can penetrate deep into turbid media. The concept of OCT was developed at the Massachusetts Institute of Technology (MIT) under the lead of Dr. James G. Fujimoto (mid twentieth century), with team members Carmen A. Pulliafito (mid twentieth century), Eric A. Swanson (mid twentieth century), and David Huang (mid twentieth century) in the late 1980s. The fact that most media and solid objects have light SCATTERING properties, the loss of light due to scattering before returning to the point of introduction at the surface for collection and process provides significant reduction in signal strength. The impact of scattering on the signal quality in the optical interrogation of turbid media places significant constraints on the imaging modality. On the positive side, the in-site high-resolution imaging can be performed under relatively low instrument cost. The OCT technology does not require expensive high-powered laser sources and can be used in FIBER-OPTIC mode or free-space. OCT has an axial resolution of better than $3\text{ }\mu\text{m}$ and lateral in the order of μ , with depth of probing exceeding 3 mm. The depth resolution is a function of the coherence length of the broadband source. The LATERAL RESOLUTION is a function of the device dimensions, specifically the tip diameter of the fiber-optic probe. The depth resolution is directly proportional to the coherence length, where the coherence length (L_c) is defined by the bandwidth ($\Delta\lambda$) of the source with respect to the central wavelength (λ_0): $L_c = (2 \log 2 / \pi) (\lambda_0^2 / \Delta\lambda)$. For a super-luminescent DIODE, the bandwidth is in the order of $\Delta\lambda = 32\text{ nm}$ with inherent resolution $\text{Res}_{\text{ax}} = 10\text{ }\mu\text{m}$, alternatively a MODE-LOCKED LASER will provide $\Delta\lambda = 350\text{ nm}$ with inherent resolution $\text{Res}_{\text{ax}} = 1.5/n\text{ }\mu\text{m}$, n the index of REFRACTION of the medium. The bandwidth of the pulse laser is defined by the pulse width (Δt) as $\Delta\nu\Delta t \geq 1/(4\pi)$, $\nu = c/\lambda$ the frequency of the ELECTROMAGNETIC RADIATION and c the speed of light. The probing mechanism of the OCT is not a stationary process. In order to provide accuracy about the true maximum signal strength at the balance interferometer depth in the medium a process called “heterodyning” is applied, providing a perturbation around the equilibrium position. Heterodyning ensures the isolation of the exact magnitude of positive interference for all wavelengths in the wave package from the broadband source. By changing the length in the reference arm on a fixed periodic interval (with angular frequency ω_h ; frequency ν_h), the acquired signal from the equilibrium depth will fluctuate over time in depth. The source signal is modulated by frequency $\nu_{h,1}$ and the detected signal will be modulated at frequency $\nu_{h,2}$ which yields the interference signal at the detector: $\Psi(t) \propto A^2(t) = (A_{1,0}^2/2) + (A_{2,0}^2/2) + A_{1,0}A_{2,0} \cos(2\pi[\nu_{h,1} - \nu_{h,2}]t) \propto \text{Voltage}(t)$ with $A_{i,0}$ the respective electric field amplitude in the reference

signal and sample signal. The modulation of the detection (sample) signal provides a mechanism of phase-locked detection (similar to what is applied in RADIO receivers). This interference signal fluctuates with the BEAT FREQUENCY (ν_b) with respect to the two modulations. The heterodyning provides a significant increase in the signal-to-noise ratio, better than 140 dB. The envelope of this signal contains the information pertaining to the three-dimensionally defined location inside the medium to be used for tomographic image reconstruction. Additionally, the path-difference between the reference arm of the interferometer and the sample arm introduces a time delay: $\tau_{\text{interferometer}} = (L_1 - L_2)/c = (d_{\text{diff}}/c)$ which influences the “visibility” of the interference fringe. The fringe “intensity” is a function of the spectral bandwidth and the path difference as $S(\tau_{\text{interferometer}}) = \int_{\nu_{\min}}^{\nu_{\max}} S(\nu) [1 + \cos(2\pi\nu\tau_{\text{interferometer}})] d\nu$. This in turn translates into a visibility function for the fringe that is the relative difference between the minimum intensity and the maximum intensity: $V_{\text{vis}}(\tau) = [(S(\tau)_{\max} - S(\tau)_{\min}) / (S(\tau)_{\max} + S(\tau)_{\min})] = S_0 \{1 + U(\tau) \cos[2\pi\nu_0\tau + \phi(\tau)]\}$, where $\phi(\tau)$ is the phase shift, and $U(\tau) = \exp(-(d_{\text{diff}}/L_c))$ is the envelope of the heterodyne function. With this algorithm, very accurate and sensitive measurements of the localized optical parameters can be performed, thus identifying the medium based on documented reference table of optical parameters and optical effects. Using all the electromagnetic properties various types of OCT devices have been developed, in combination with specific computational techniques: POLARIZATION sensitive, phase resolved, spectroscopic, time-domain, DOPPLER, and Fourier domain. Each respective technique can provide certain particulars about the medium under optical interrogation. The most well-known imaging applications for OCT are for the RETINA of the EYE. Additional application are also found in the intestines by means of endoscopic probing, as well as the investigations of SKIN with respect to for instance stage and spread of cancer growth. The imaging modalities are still relatively confined to surface applications (see Figure O.27).

Figure O.27 Optical coherence tomography image. (Courtesy of the Bioptigen, Raleigh, North Carolina.)

Optical density (OD)

[general, optics] Optical attenuation quantity that uses the LOGARITHM of the value for the attenuated radiance with respect to the incident light for a specific optical component and is not referenced against the thickness of the medium: $OD = -\log_{10} T$, where T represents the transmission of light in standard units, usually determined in derived unit of “voltage” based on the sensor unit, detection mechanism and SIGNAL acquisition. The optical density of a medium will be a function of wavelength and has no units.

Optical magnification

[biomedical, engineering, general, optics] Two types of magnification can be distinguished: angular magnification and lateral magnification. Lateral magnification is the ratio of the size of the IMAGE (i) to the object size (o): $M_{\text{mag}} = -(i/o)$, where the sign indicates the relative orientation of the image with respect to the object. Angular magnification indicates the observed size by the EYE based on the ANGLE that the object subtends to the eye, where the angle is measured with respect to the optical axis: $M_{\text{mag}} = \theta/\theta_N$, where θ_N is the relative angle from the NEAR-POINT of the eye ($\sim 0.25m$): $\theta_N = b/0.25m$, with b the “height” (vertical length) of the object, and θ the angle at which light rays enter the eye (using the rays originating from the edges for maximum value) (see [Figure O.28](#)).

Figure O.28 (a,b) Magnified view of insect compound eye.

Optical path length (O.P.L.; D)

[biomedical, general, optics] The average DISTANCE light can travel in a turbid medium before it is annihilated between SCATTERING interaction and absorption, based on a PROBABILITY distribution of the relative

proportions for both events: $D = 1 / [\mu_a + (1 - g)\mu_s]$, where μ_a is the ABSORPTION COEFFICIENT, μ_s is the SCATTERING coefficient, and g is the scattering anisotropy factor (see Figure O.29).

Figure O.29 Representation of five photons traveling in a turbid medium until each respective photon is finally absorbed or leaves the medium through backscatter. The optical free path for air is virtually infinite, providing blue-skies and red sunsets.

Optical sensing

[electromagnetism, optics, theoretical] Any mechanism that relies on light or ELECTROMAGNETIC RADIATION as the means to derive a physical property of a medium or a biological specimen. The detection mechanism will use a sensor unit that converts the quantity of light (i.e., fluence or radiance) in an electric SIGNAL for further processing. Detection can be performed by a variety of photoelectric devices; pin diodes, solar CELL, PHOTO-MULTIPLIER TUBE, DIODE as well as chemical and mechanical devices such as the ELASTOMER polydimethylsiloxane (PDMS, a pressure sensor polymer). One specific application of optical sensing is in character recognition, retinal scans and the like, based on a two-dimensional pattern of light and dark (see Figure O.30).

(a)

(b)

Figure O.30 (a) Optical fingerprint recognition using ultraviolet light and (b) to detect the greasy imprint of the pattern of ridges on the fingertip.

Optical spectra

[optics] The wavelength content of the collected light after interaction with a medium, generally resulting from a broadband LIGHT SOURCE. There are several kinds of spectra that can be distinguished based on the manner it is created or the mechanism of action involved in the formation of the emitted LIGHT. Two kinds of spectra are recognized: ABSORPTION and EMISSION. The emission spectra, for instance, is the creation of light from a high TEMPERATURE SOLID, liquid, or dense gas, which will be continuous, whereas a low pressure GAS will emit a LINE or BAND spectrum. An ABSORPTION SPECTRUM will display gaps representative of the ELEMENTS in the exposed medium. Specific spectral analysis techniques are available to retrieve specific details about the light-matter interaction. The specific light interaction on a molecular or atomic level can provide identification mechanisms for the presence and volumetric MAGNITUDE of chemical constituents. Molecular spectra can be recognized based on ELECTRON SPIN states (specifically electron paramagnetic resonance), molecular VIBRATION, molecular rotation, atomic scissor-action within the MOLECULE, as well as electronic states. Specific spectroscopic analyses include, for instance, Raman spectroscopy, vibrational circular dichroism spectroscopy, hyperspectral imaging, and laser-induced breakdown spectroscopy (see [Figure O.31](#)).

Figure O.31 Chart representing color temperature, broad spectral emission from solids.

Optically dense

[optics, solid-state] Solid, liquid, or gas that has a molecular separation that is smaller than the wavelength of the light incident on the medium. For both solids and liquids, the molecular spacing is of the order of 20–30 nm. For gases, the conditions under standard temperature and pressure yield on average a separation of 300 nm. Under all of these circumstances, the internal electric field may be associated with a DIPOLE. The molecules in suspension experience an electric external field, such as the ELECTROMAGNETIC RADIATION, as well as a secondary field produced by neighboring molecular dipoles. The external field produce an OSCILLATING DIPOLE moment with associated RADIATION. This entails that the molecules in an optically dense medium will be coupled. The net result of electromagnetic (EM) radiation interaction with an optically dense medium is a superposition of the molecular interaction with the incident WAVE. The re-emitted wave can in bulk be described by either Mie or RAYLEIGH SCATTERING theory, depending on the respective wavelength ranges. At the interface between two media with a large quantity of homogeneously distributed molecules, the presumably randomly re-emitted light converts on average into SNELL'S LAW for the refracted light.

Optics

[general] Scientific discipline that investigates and utilizes ELECTROMAGNETIC RADIATION, primarily the visible spectrum, but not limited to that. Optics deals with REFRACTION, diffraction, reflection, IMAGE formation, LENS design, spectral analysis and general ENERGY transfer, FLUORESCENCE, as well as general atomic and molecular interactions. Optics investigates both the PARTICLE aspect of photons as well as the WAVE property. Optics is also engaged with the design and development of physical detection mechanisms available for diagnosing and quantifying electromagnetic radiation and its sources. Most optical interactions can be described on a rigorous level with MAXWELL EQUATIONS. The interaction of light rays at an interface can be described by geometric optics, applying laws of refraction and reflection on rays representing the path of photons. Physical optics applies to a more comprehensive model of light, including the wave phenomena, explain experiences such as diffraction and INTERFERENCE that cannot be accounted for using geometric optics. Most optical phenomena can be accounted for using a classical electromagnetic description, however, phenomena that rely on both the wave and particle properties requires a QUANTUM mechanical approach. Historically optics can be traced back as far as the ancient Egyptians and Mesopotamians in 700 BC, for their use of lenses made from polished crystal, often QUARTZ. The development of the MICROSCOPE formed an important breakthrough in 1595 by HANS JANSEN (sixteenth century, no exact dates), next to the design of the refracting TELESCOPE in 1608 by HANS LIPPERSHEY (1570–1619). Up to the proposition of the wave

theory of light by CHRISTIAAN HUYGENS (1629–1695) in 1690, the ray (corpuscular) theory of light prevailed. Visual perception (VISION) forms a small but important aspect of optics (see Figure O.32).

Figure O.32 (a) Huygens wavefront. The eye also performs an optical inspection, which is spectrally interpreted by the brain, warning the consumer about (b) rotten fruit or (c,d) moldy cheese.

Optoacoustic imaging

[optics, thermodynamics] See PHOTO-ACOUSTIC IMAGING.

Orbital angular momentum

[atomic, nuclear] Property that may refer to either electromagnetic waves or a QUANTUM MECHANICS angular momentum operator. In general classical mechanics, the operator for the angular momentum is the cross product of the direction ($\vec{r}$) and the moment ($\vec{p} = m\vec{v}$): $\vec{L} = \vec{r} \times \vec{p}$. For a body (of any shape) rotating around a central axis the body will be constructed of a finite number of mass ELEMENTS with respective angular momenta that are linked to the MOMENT OF INERTIA of these respective elements (combining to the rigid body): I , as $L = M_0 v_t r$, with v_t the tangential component of the velocity, M_0 the mass of the PARTICLE at orbit radius r . Under the condition of no torque resulting from central force, alternatively: $L = I\omega$, where ω is the ANGULAR VELOCITY. On an atomic level, the angular momentum will describe the orbits of ELEMENTARY PARTICLES and the description will require a quantum mechanical approach. In case the potential ENERGY for the atomic structure depends only on the DISTANCE $\vec{r}$, the WAVE EQUATION can ultimately be solved and separated to yield the angular component. In classical mechanics, the angular momentum will always be conserved due to the absence of external torque. Under quantum-mechanical approach the orbital angular momentum for a particle subject to a central potential will have EIGENVALUE solutions. In a spherical coordinate system (r, θ, ϕ), the various components of the orbital angular momentum can be derived from the respective operator; $L_{op}^2 = L_{x,op}^2 + L_{y,op}^2 + L_{z,op}^2 = -\hbar^2 \left[(1/\sin \theta)(\partial/\partial \theta)(\sin \theta(\partial/\partial \theta)) + (1/\sin^2 \theta)(\partial^2/\partial \phi^2) \right]$, which does not depend on r ; where $\hbar = h/2\pi$, $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ Planck's constant. The z -component: $L_{z,op} = (\hbar/i)(\partial/\partial \phi)$. The ensuing angular momentum now becomes: $L = \hbar\sqrt{\ell(\ell+1)}$, where ℓ is the orbital angular momentum quantum number, which stands in contrast to the classical mechanics Bohr angular

momentum: $L_z = m\hbar$, now obsolete for atomic MOTION. Note that the z -component still satisfies the Bohr equivalent as $L_z = m\hbar$, where m is other quantum number characterizing the spherical harmonic functions as solutions to the SCHRÖDINGER EQUATION with wavefunction $\psi_{n,\ell,m}$, where n is the primary quantum number. The PARITY of the wavefunction is dependent only on the angular part of the function. The parity of the harmonic oscillator indicates the symmetry or antisymmetry of the WAVEFUNCTION: $\psi_{n,\ell,m} = \psi_{n,\ell,m}(-x)$, or respectively $\psi_{n,\ell,m} = -\psi_{n,\ell,m}(-x)$, and is defined by the ORBITAL ANGULAR MOMENTUM QUANTUM NUMBER (ℓ) as $Parity = (-1)^\ell$.

Orbital angular momentum quantum number (ℓ)

[atomic, general, nuclear] Integer characterizing the spherical harmonic functions of the atomic wavefunction, defined as one of the QUANTUM numbers. In solutions to the SCHRÖDINGER EQUATION ($H\psi = E\psi$), the wave functions ψ are obtained, which describes the PROBABILITY of finding electrons at certain ENERGY levels within an ATOM. The WAVE functions for the electrons are called “atomic orbitals.” The electrons in an atom are described by four quantum numbers. The first three quantum number are specifying the particular orbital of interest (PRINCIPAL QUANTUM NUMBER n , angula quantum number ℓ , and MAGNETIC QUANTUM NUMBER m_ℓ), while the fourth specifies how many electrons can occupy that orbital (spin quantum number m_s), also referred to as “azimuthal quantum number” (see [Figure O.33](#)).

Figure O.33 Orbital angular momentum of a spinning top providing the torque to allow the top to hang at an angle with a suspension sling (i.e., gyroscope effect).

Orbital magnetic moment

[atomic, nuclear] Quantum number used to define the orientation in space of an electron orbit of a given ENERGY (n) and shape (ℓ). The QUANTUM number subdivides the SUBSHELL into individual orbitals; each subshell holds respective electrons, with $2\ell + 1$ orbitals in each subshell.

Orbital magnetic quantum number (m_ℓ)

[general] Quantum number defining the orientation in space of an orbital for a given ENERGY (n) and shape (ℓ); $m_\ell = -\ell, \dots, 0, \dots, \ell$. A sphere ($\ell = 0$) can only be oriented in one way in space. On the other hand, orbitals that have different shapes, such as polar ($\ell = 1$) or cloverleaf ($\ell = 2$), can have an orientation in different directions. A third quantum number is therefore needed to define the orientation in space of the orbital. The MAGNETIC QUANTUM NUMBER is named this way since the different orientations of orbitals were first observed under the influence of an external magnetic field. This QUANTUM NUMBER is one of three

coordinates that result from solving the Schrödinger wave equations, providing the principal (n), angular (ℓ), and magnetic (m_ℓ) quantum numbers. These quantum numbers describe the size, shape, and orientation in space of the orbitals on an ATOM. In contrast to the Bohr model, which is a one-dimensional model that only uses one quantum number to describe the size with respect to the distribution of electrons in the atom. This quantum number subdivides the SUBSHELL into individual orbitals which hold the electrons; there are $2\ell + 1$ orbitals in each subshell. In this light, the s subshell has only one orbital, subsequently the p subshell has three orbitals, ensuing for the following ELECTRON SHELLS.

Orbital quantum number, (ℓ)

[high-energy, nuclear, quantum, solid-state] See ORBITAL ANGULAR MOMENTUM QUANTUM NUMBER.

Orbital velocity

[computational, fluid dynamics, mechanics, thermodynamics] There are three specific cases of orbital velocity: the speed of a body in orbital under the influence of a GRAVITATIONAL FIELD; the velocity pattern of MOTION of particles in WAVE MOTION, in particular in water and wind waves; the equivalent SCHRÖDINGER WAVE EQUATION velocity of a bound electron required to maintain its orbital kinetic ENERGY. Generally, the orbital velocity describes a balance in two forces, yielding a tangential velocity, and angular velocity (see ANGULAR VELOCITY) (see Figure O.34).

Figure O.34 Concept of orbital velocity for geosynchronous telecommunication satellite.

Orbits

[general] Revolution of an object (man-made or natural) moving in a pattern around another celestial body. The EARTH is in orbit around the Sun. Near-circular orbits are called “Keplerian.” Satellites revolve by remaining in a fixed location with respect to the earth’s geometry, so that we do not have to adjust the (dish-) ANTENNA aimed at the SATELLITE used for television reception. The fixed location with respect to Earth refers to the fact that the satellite is in the GEOSYNCHRONOUS ORBIT or GEOSTATIONARY ORBIT. Spy satellites and weather satellites, on the other hand, are moving around in variable or predetermined patterns, scanning the surface in a grit-pattern. Other forms of orbital motion are equatorial orbit,

graveyard orbit, low Earth orbit, medium Earth orbit, MOLNIYA ORBIT, polar orbit, subsynchronous orbit, and supersynchronous orbit (*also see* EARTH SATELLITE) (see [Figure O.35](#)).

Figure O.35 Examples of orbit: (a) atomic orbit diagram, (b) planetary orbits in our solar system, and (c) a space station in orbit with an approaching space shuttle. (Courtesy of NASA)

Orbits in hydrogen atom

[atomic, nuclear] The COULOMB POTENTIAL for the HYDROGEN ATOM is primarily spherically symmetric and can be defined as a radially dependent function: $V = V(r) = -(Ze^2/4\pi\epsilon_0 r)$, where Z is the charge number, $e = 1.60217657 \times 10^{-19} \text{ C}$ the electron charge, r the DISTANCE to the core, and $\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{Nm}^2$ the permittivity of free space. The angular momentum operator applied to the WAVEFUNCTION yields a description that is only a function of the radius ($R(r)$): $(1/r^2)(d/dr)[r^2(dR(r)/dr)] + (2\mu_m/\hbar)[E + (Ze^2/4\pi\epsilon_0 r) - (\ell(\ell+1)\hbar^2/2\mu_m r^2)]R(r) = 0$, with SOLUTION $R(r) = G(r)e^{-(r/a_0)}$, where $G(r)$ is the GREEN'S FUNCTION power series truncated to a polynomial (if not, the solution will diverge), $a_0 = 4\pi\epsilon_0\hbar^2/Z\mu_m e^2$ the Bohr first radius ($a_n = n(a_0/Z)$), $\mu_m = m_1 m_2/(m_1 + m_2)$ the REDUCED MASS, m_i the

respective masses of the system, $E_n = -(\mu_m Z^2 e^4 / 32 \pi^2 \epsilon_0^2 \hbar^2 n^2)$, where n is an integer that is greater than the angular quantum number ℓ , $\hbar = h / 2\pi$, $h = 6.62606957 \times 10^{-34}$ m²kg/s Planck's constant (see [Figure O.36](#)).

Figure O.36 Energy levels for orbital electron in atoms, including hydrogen.

Orbits of particles in water waves

[fluid dynamics] The WAVE-MOTION of the water surface can in principle be described as a circular MOTION of the individual water molecules (see [Figure O.37](#)).

Figure O.37 (a) Diagram of water segments performing orbital motion, with the greatest “amplitude” at the surface. (Continued)

(b)

(c)

Figure O.37 (Continued) (b) "surf" wave, used for "surfing", and (c) types of waves.

Ordinary differential equations

[computational] Mathematical expression describing a function of one single independent variable and the respective derivatives of this variable in various orders, for instance $[dy(t)/dt] = f(t, y(t))$. This stands in contrast to a "partial differential equation," which may include terms with respect to more than one independent variable.

Oresme, Nicolas (1320–1382)

[computational, general] Scientist and philosopher from France, also known as Nicole Oresme, Nicolas d'Oresme, or Nicholas Oresme. Oresme's work provided elementary foundations for the development of advanced mathematics as well as his contributions on the mathematical definitions in science. Oresme is also respected as the greatest medieval economist. Most of his scientific and economic work was based on the elementary work of ARISTOTLE (384–322 BC) (see [Figure O.38](#)).

Figure O.38 Nicolas Oresme (1320–1382).

Organ of Corti

[acoustics, biomedical, electronics, general] Auditory ELEMENT in the cochlea of the INNER EAR. The cochlea has a spiral shape, resembling a snail shell. The organ of Corti is found on the scala-media side on the BASILAR MEMBRANE. The Organ of Corti derived its name from the pathologist Marquis Alfonso Giacomo Gaspare Corti (1822–1876) from Italy who described it. The receptor aspect of the organ of Corti has two types of receptor cells: the inner hair CELL and the outer hair cell. Each of these hair cells have different functions. The organ of Corti contains two rows of rod cells, arranged on the MEMBRANE in the form of a minute arch. To the arch, four rows of hair cells are fixed, consisting of one row on the inner side and three on the outer side. The function of the Organ of Corti is the conversion of SOUND vibrations into nerve pulses. The sound waves are transmitted along the cochlear duct, which form a LONGITUDINAL WAVE that results in the displacement of the tips of the hair, and as such flexing the hair which in turn generates an action-potential. These action-potential impulses are transmitted by the auditory nerve, or cochlear nerve, to the brain, at which location they are interpreted as sound with the frequency associated with the location on the basilar membrane. The detection of long wavelengths are farther into the cochlea (toward the apex), whereas the high frequency are detected close to the entry point at the oval membrane (the base) (see [Figure O.39](#)).

Figure O.39 Organ of Corti, as part of the cochlea, part of the "inner-ear".

Organic scintillator

[nuclear] In NUCLEAR MEDICINE generally there are three types of scintillators: inorganic crystals and organic scintillators next to photomultiplier tubes. Each type of scintillator has the general function of converting ionizing radiation (short wavelength X-RAY; high ENERGY particles), as well as NEUTRON rays, in lower energy photons that can be detected with photocells, photographic film, or the HUMAN EYE. The electronic detection will allow for digital storage, as provided by charge-coupled device array detectors. In inorganic or crystalline detectors, the scintillation mechanism is a direct function of the structure of the crystal LATTICE, using the IONIZATION aspects of energy transfer between selected energy bands. Organic scintillators provide

detection based on the FLUORESCENCE mechanism arises from transitions in the energy levels of a single molecule due to the incident ionizing radiation, no crystalline structure required. Fluorescence is as such detected independently of the physical state of the medium. Organic scintillators are generally composed of aromatic hydrocarbons. An example of an organic scintillator is anthracene as a fluorescent medium. Scintillators are used for X-ray detection (e.g., computed TOMOGRAPHY scan), GAMMA RAY detection, as well as high energy particle PHYSICS. Organic scintillators are generally more useful in high energy X-ray detection and have limited spectroscopic application, depending on the design; primarily, in PARTICLE spectroscopy (neutrons and charged particles). Plasticized organic scintillators have superior response time of a few nanoseconds (see Figure O.40).

Figure O.40 (a) Principle of organic scintillator and (b) Photomultiplier tube.

Orifice

[fluid dynamics, thermodynamics] An opening, puncture, hole, exhaust, vent, void, or mouth, such as those found in a tube, PIPE, conduit, plate, or a body of material (organic or inorganic). An ORIFICE plate is a tool designed to measure FLOW rate, and can be used to reduce pressure or restrict flow.

Orifice, flow restrictions

[fluid dynamics] In any FLOW system, there is often the desire to control either the flow and pressure pertaining to that LIQUID. Pressure and flow are interdependent yet different. Controlling the flow or pressure can affect the other and the mechanism of control can lead to unexpected, inconsistent, or even “disastrous” results. Both pressure and flow control can be achieved, under the proper conditions, using a restriction in the plumbing line. Common tools are manual valves and fixed orifices of varying dimensions. Examples are found in kitchen and bathroom faucets, also known as “restrictive flow orifices.”

Ørsted, Hans Christian (Oersted) (1777–1851)

[energy, general, optics] A Danish scientist. Together with ANDRE-MARIE AMPÈRE (1775–1836) their groundbreaking work led to the revelation of the link between ELECTRICITY and MAGNETISM in 1819, resulting in an upsurge in the theoretical and experimental efforts in this field (see [Figure O.41](#)).

Figure O.41 Hans Christian Ørsted (1777–1851) (Oersted).

Orthogonal function

[atomic, computational] Functions that are perpendicular to each other, as considered a generalized version of vectors. The analysis of periodic functions with FOURIER ANALYSIS yields orthogonal functions. Two functions (ϕ) are orthogonal within a segment (a, b) if the dyadic expression yields: $\int_a^b \phi_m^* \phi_n dx = 0$, where ϕ_m^* is the complex conjugate. Examples of orthogonal functions are BESSEL FUNCTIONS, Chebyshev polynomials, Hermite polynomials, Legendre polynomials, sine and cosine, Spherical harmonics, Walsh functions, and Zernike polynomials, and generally EIGENFUNCTION with different eigenvalues are also orthogonal (e.g., Hamiltonian). One specific example of orthogonality applies to the Legendre polynomials, also referred to as “Legendre functions of the first kind,” or “zonal harmonics,” which are solutions to the LEGENDRE DIFFERENTIAL EQUATION. The Legendre polynomials are orthogonal over the segment $(-1, 1)$ as defined $\int_{-1}^1 \phi_m(x) \phi_n(x) dx = [2/(2n+1)]\delta_{mn}$, where δ_{mn} is the Kronecker delta.

Oscillating dipole

[general] Dipoles can be electronic, MAGNETIC, or mechanical (ACOUSTICS, FLUID DYNAMICS). A DIPOLE source consists of two monopole sources of equal strength but opposite PHASE (mechanical, acoustic) or opposite charge (atomic/molecular), separated by a small DISTANCE in relation to the wavelength of emission. Molecular dipoles are the most common and reveal information about material properties. Molecular dipoles were studied in great detail by PETER J. W. DEBYE (1884–1966), a chemist from the Netherlands. As a consequence, dipole moments are measured in “debye” units in his honor. Oscillating dipoles will produce some form of radiating ENERGY,

electromagnetic, and mechanical. An example of the electronic dipole is an analog ANTENNA. When the dipole is much shorter in length than the wavelength of the emitted radiation, the emitted POWER (P) at specific oscillation FREQUENCY ($\nu = \omega/2\pi$, ω the ANGULAR VELOCITY) as a function of the SOLID ANGLE (Ω) of the antenna can be defined as $dP/d\Omega = (\omega^4 P_0^2 / 32\pi^2 \epsilon_0 c^3) \sin \theta$, where P_0 is the power at the source, $\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{Nm}^2$ is the permittivity of free space, and $c = 2.99792458 \times 10^8 \text{ m/s}$ is the speed of light.

Mechanical examples are an unboxed SPEAKER or a two-beater kitchen mixer in a highly viscous medium (e.g., dough), generates a dipole FLOW field, with an acoustic dipole as the oscillating representative model. On more simplified terms, the oscillating acoustic dipole generates a convolution of “BUBBLE flow.” Both pressure and velocity distributions have to be of the form of a SPHERICAL WAVE. The VELOCITY POTENTIAL (Φ_{bubble}) of a single oscillating bubble is described as $\Phi_{\text{bubble}} = (1/2)A(t)r^2(3\cos^2\theta - 1)$, where $A(t)$ is the periodic AMPLITUDE (generally expressed as pressure P or displacement), r is the radius to the source, and θ is the angle with the axis. The acoustic radiation field of a dipole (bipole), pair of two identical monopoles separated by a distance d (small with respect to the wavelength), can be represented as follows: $P(r) = P_0(e^{-i(kr_1 - \omega t)}/r_1) + P_0(e^{-i(kr_2 - \omega t)}/r_2) \equiv 2P_0(e^{-i(kr - \omega t)}/r)\cos(k\sin(\theta d/2))$, where P represents pressure, $k = 2\pi/\lambda$ is the wavenumber for wavelength λ , and t is the elapsed time (see Figure O.42).

Figure O.42 Oscillating dipole.

Oscillating spring

[acoustics, electronic, fluid-dynamics, general] A MASS (m) attached to a spring that is extended by an external force (F_{ext}) will produce an OSCILLATION that can be damped (critically damped or, or under special conditions, may produce a non-damped HARMONIC OSCILLATION. The restoring force is produced by the extension and follows Hook's law: $\overline{F_{\text{spring}}} = -k\vec{x} = m(d^2/dt^2)\vec{x}$, where k is the spring constant and $\vec{x}$ is the

displacement. The solution to the nondamped oscillation as a function of time (t) provides a sinusoidal OSCILLATION described as $\vec{x}(t) = A \cos(\omega t + \phi)$, where A is the AMPLITUDE of the MOTION, the length of stretch of the spring, $\omega = \sqrt{k/m}$, and ϕ a PHASE factor. For the damped oscillation, the amplitude will decrease with time resulting from a “frictional force” ($F_{\text{friction}} = -b\vec{v}$, proportional to the velocity $\vec{v}$, with dampening factor b) described as $-k\vec{x} - b\vec{v} = -k\vec{x} - b(d\vec{x}/dt) = m(d^2/dt^2)\vec{x}$, with solution: $\vec{x}(t) = A_0 e^{-\lambda_{\text{damp}} t} \cos(\omega t + \phi)$, where $\lambda_{\text{damp}} = -(b \pm \sqrt{b^2 - 4mk}/2m)$; note there are two extreme situations next to the regular damped oscillation: overdamped $b^2 > 4mk$, and underdamped $b^2 < 4mk$. Generally, the square root will be positive with a real solution, whereas an underdamped situation may have an imaginary root solution. The DECAY time of the damped oscillation is $\tau_{\text{decay}} = 2m/b$. For the overdamped situation, the extended spring will return to the equilibrium position without oscillation, gradual exponential decay in extension only. In case a RESONANCE force is applied in a continuous fashion in a sinusoidal format, the oscillation will satisfy: $F_{\text{net}} = -k\vec{x} - b(d\vec{x}/dt) + F_0 \cos(\omega' t + \vartheta) = m(d^2/dt^2)\vec{x}$, which will oscillate at the driving frequency ω' and driving amplitude (see Figure O.43).

Figure O.43 (a) Oscillating spring. A spring can oscillate in transverse and longitudinal direction, the most common transverse spring oscillation is a vibrating string such as one found on a (b) guitar. (Continued)

(c)

(d)

(e)

Figure O.43 (Continued) (c–e) A trampoline is a complex spring, with stretch of material and suspension springs. Additional attractions are in bungee jumps.

Oscillation

[electromagnetism, general, mechanics] Periodic MOTION, repeatedly fluctuating above and below an arbitrary mean value. Examples are the pressure pattern in SOUND waves, electromagnetic signals as well as periodic solutions to mathematical equations (*also see* SIMPLE HARMONIC OSCILLATION). Oscillations can be driven by various sources and have external influences. A natural oscillation will require a start-up force and may remain in harmonic displacement (displacement distance: $s(t)$) as a function of TIME (t) indefinitely (i.e., free oscillation, without continuous driving force or undamped oscillation with continuous driving force); however, most oscillations require a continuous driving force or OSCILLATOR (e.g., FORCED OSCILLATION) or will eventually extinguish due to frictional or dampening forces (e.g., damped oscillation). A forced oscillation will result in RESONANCE as a function of time (t), under an external harmonic driving force ($F_{\text{ext}} = F_0 \sin(\omega_{\text{ext}} t)$), with ω_{ext} being the external oscillation angular frequency) to obey the WAVE EQUATION: $m(d^2x/dt^2) + b(dx/dt) + kx = F_0 \sin(\omega_{\text{ext}} t)$, where b is the dampening coefficient and k is the spring constant. Damped oscillation is the oscillation dampened by external frictional force (F_E)

with steady-state solution: $x = A \cos(\omega_{\text{ext}} t + \phi)$, where $A = (F_{e0}/m)/\sqrt{[(\omega_0^2 - \omega_{\text{ext}}^2)^2 + b^2(\omega_{\text{ext}}^2/m^2)]}$, and $\omega_0 = \sqrt{k/m}$. An example of a frictional force while the body with mass m in motion with displacement $s(t)$ is submerged in a LIQUID is defined proportional to the velocity (v) as $F_E = -b\vec{v} = -b[d\vec{s}(t)/dt]$, where b is the dampening constant and v is the velocity of motion, which yields NEWTON'S SECOND LAW as follows: $\sum F = ma = -ks - b[ds(t)/dt] = m[d^2s(t)/dt^2]$, where $a = [d^2s(t)/dt^2]$ is the acceleration experienced by the body in linear motion. Forced oscillation happens when a sinusoidal force is applied continuously and there will be three forces operating: a restoring SPRING FORCE, a frictional force, and an external oscillating driving force (F_E) with its own operating frequency (ω_E), yielding under Newton's second law: $\sum F = ma = -ks - b[ds(t)/dt] + F_E \sin(\omega_E t) = m[d^2s(t)/dt^2]$. Generally, an oscillation can reach a very high AMPLITUDE under resonance conditions, and in this case, the driving frequency matches the NATURAL FREQUENCY of the harmonic oscillator in one of the harmonic states, the resonant angular frequency: $\omega_R = \sqrt{\omega_0^2 - (b^2/2m^2)}$, which reduces to the NATURAL ANGULAR FREQUENCY ($\omega_0 = \sqrt{k/m}$) when the dampening is negligibly small (*also see* MASS-SPRING SYSTEM). In an electric system consisting of capacitors, inductors and resistors with a driving harmonic voltage source the equations are as follows. The sine-wave oscillator voltage source (V) is defined by both an INDUCTOR and a CAPACITOR with current (i) and inductance (L): $V = L(di/dt)$ and capacitance C , yielding $i = C(dV/dt)$. Combining both components gives $i + LC(d^2i/dt^2) = 0$, with undamped resonance ANGULAR-FREQUENCY $\omega = 1/\sqrt{LC}$ or frequency $\nu = 1/(2\pi\sqrt{LC})$ and solution $i = A \sin(\omega t + \phi)$, where ϕ is an undefined phase constant and A is a boundary condition dependent constant; this frequency has significant similarity to the PENDULUM frequency described by Galileo. When adding a dampener such as a RESISTOR (R) to the circuit, the differential equation becomes $i + RC(di/dt) + LC(d^2i/dt^2) = 0$, with an exponentially decaying solution: $i = Ae^{-(t/\tau)} \sin(\omega t + \phi)$, where τ is a factor indicating the DECAY time. Generally, the voltage output of the current driven oscillator is defined as $V_{\text{out}} = R_A i_{\text{in}}$, where R_A is the gain of the oscillator (technically a negative value with units of RESISTANCE [Ω]). In case the gain could be matched to a physical resistance, then the oscillator would be described by the undamped equation; however, there are many factors in the gain that cannot be matched by a linear resistance (e.g., phase shift and other nonlinear properties), which requires the introduction of a nonlinear amplifier that has a higher gain at low voltages and a low gain at a high voltage. This nonlinearity changes the format and the amplifier can, for instance, be CUBIC, which allows it to be described by the VAN DER POL EQUATION: $(d^2\xi/dt^2) + \epsilon(\xi^2 - 1)(d\xi/dt) + \kappa = 0$, where ξ is an electronic identity (current or potential) that varies with time t , whereas ϵ is a coefficient indicating dampening and attenuation in combination with COMPLIANCE, including system nonlinearities. Another form of oscillation is in RESONANCE. Mechanical resonance can be achieved by means of a PIEZOELECTRIC actuator. The piezoelectric oscillation has both mechanical and electrical influences, where the electric part can be represented by a Colpitts oscillator operating with frequency: $\nu = (2\pi\sqrt{L[C_1C_2/(C_1 + C_2)]})^{-1}$, where the inductor is represented by the piezoelectric crystal. (*also see* RESONANCE and PIEZOELECTRIC RESONANCE). An entirely different type of oscillation is in chemical binding where the chemical reaction changes periodically in time or location toward a higher entropy or a lower state of Gibbs free ENERGY. The increase in entropy is represented by an increase of product with an associated decrease in reactants through an intermediate reaction product. The rate of formation and destruction of intermediate dictates the chemical component oscillation process in both time and space. This process is referred to as OSCILLATORY REACTION (see Figure O.44).

Figure O.44 (a,b) Generalized oscillation and (c) mass oscillating between elastic barriers.

Oscillator

[general] Mechanical or electronic mechanism of action resulting in a HARMONIC OSCILLATION of a specific medium including but not limited to electromagnetic (e.g., light and radio), electric (e.g., alternating current [AC] voltage), spring (e.g., tuning fork), molecular (i.e., temperature), and SOUND (e.g., vocal cords, drum, whistle, and woofer) (*also see* MASS–SPRING SYSTEM) (see [Figure O.45](#)).

(a)

(b)

Figure O.45 (a,b) Vocal cords oscillator.

Oscillator quantum number

[nuclear] In atomic PHYSICS, the particle MOTION becomes subject to the SCHRÖDINGER EQUATION due to fact that the QUANTUM harmonic oscillator is the quantum-mechanical equivalent to the classical harmonic oscillator. The application of an arbitrary electrical potential (i.e., COULOMB POTENTIAL) considered in the vicinity of a stable equilibrium point can generally be approximated as a harmonic potential. The quantum harmonic oscillator is one of the most significant mathematical systems in QUANTUM MECHANICS. The quantum harmonic oscillator can be described by the Hamiltonian of the oscillating PARTICLE (e.g., electron) with mass m as $H_{\text{opp}} = (p_{\text{opp}}^2/2m) + (1/2)m\omega^2 x_{\text{opp}}^2$, where $p_{\text{opp}} = i\hbar(\partial/\partial x)$ is the momentum operator, $\hbar = h/2\pi$, $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ is the Planck's constant, $\omega = 2\pi\nu$ is the ANGULAR VELOCITY, ν is the frequency of motion, and x_{opp} is the position operator. The Schrödinger equation now becomes $H_{\text{opp}}\Psi = E\Psi$ (this corresponds to $-(\hbar^2/2m)(d^2/dx^2)\Psi(x) + U(x)\Psi(x) = E\Psi(x)$, where $U(x)$ is the potential ENERGY EIGENFUNCTION, which can be represented for the quantum harmonic oscillator as $U(x) = (1/2)k_{\text{spring}}x^2$), with eigenvalues solutions $|\Psi$ for the WAVEFUNCTION at the energy states E , under boundary conditions described by de Broglie relationship. The SOLUTION series are $\Psi_n(x) = (1/\sqrt{2^n n!})(m\omega/\pi\hbar)^{1/4} e^{-(m\omega x^2/2\hbar)} H_n(\sqrt{(m\omega/\hbar)}x)$, where $n = 0, 1, \dots$ is the oscillatory quantum number with corresponding eigenvalues for the energy levels $E_n = \hbar\omega[n + (1/2)] = [n + (1/2)]\hbar\nu$ and $H_n = (-1)^n e^{x^2} (d^n/dx^n)(e^{-x^2})$, which are Hermite polynomials.

Oscillatory flow

[biomedical, fluid dynamics] Biological flow can be oscillatory or pulsatile, as can be system flow (e.g., piston flow or the FLOW from a water pump in an automobile). In biological systems, the RESPIRATION, vascular, and auditory flow is oscillatory pulsatile. Oscillatory flow has, for instance, the Womersley ($\alpha_{wo} = r\sqrt{\rho\omega/\eta}$, where r is the radius of the conduit, ω is the angular velocity FREQUENCY (ν) of the OSCILLATION ($\omega = 2\pi\nu$), ρ is the fluid density, and η is the VISCOSITY and Strouhal ($Sr = \nu L/v$, where v is the frequency of VORTEX SHEDDING, L is the characteristic length, and v is the velocity of flow) number as boundary conditions. Small Strouhal number will represent LAMINAR FLOW. The PULSATILE FLOW obeys the Navier–Stokes equation, and has WAVE pattern characteristics. Because of INERTIA as well as viscosity and strain, the wave movement for a FLUID in oscillatory flow will be out-of-phase over the radial velocity distribution at any location along the length of flow (see BLOOD FLOW).

Oscillatory reaction

[chemical, energy, quantum] A chemical binding reaction where the chemical reaction changes periodically in time or location toward a higher entropy or a lower state of Gibbs free ENERGY. The increase in entropy is represented by an increase of product with an associated decrease in reactants through an intermediate reaction product. The rate of formation and destruction of intermediate dictates the chemical component OSCILLATION process in both time and space. One example is the Belousov–Zhabotinsky reaction, a competing effort between two reagents: bromide (Br) and cerium (Ce). The process involves the reactive oxidation of an organic substrate by the highly reactive bromate ion (BrO_3^-), in the presence of bromide ions (Br^-) and the reaction is catalyzed by a metal ION such as the constituent ion of cerium (Ce^{3+}), which has two potential states of oxidation. The bromide ion is oxidized by bromate until the concentration drops below a threshold value when the process is replaced by the OXIDATION of the cerium ion, both reactions represented as follows: $\text{BrO}_3^- + 2\text{Br}^- + 3\text{H}^+ \rightarrow 3\text{HOBr}$ (slow) and $\text{BrO}_3^- + 4\text{Ce}^{3+} + 5\text{H}^+ \rightarrow \text{HOBr} + 4\text{Ce}^{4+} + 2\text{H}_2\text{O}$ (fast). The cerium ion reduction is in fact inhibited by the presence of the bromide ion creating the environment for a cyclic reaction. In this cyclic reaction, the bromide will be reduced in quantity until the Cesium reaction takes over again. Both the products of the bromate reaction forming a bromide hydroxyl (HOBr) as hypobromous ACID and the cesium reaction will now interact intermittently with the organic MATTER, which in turn creates the bromide ion needed to shut down the Cesium reaction in the format: $\text{Organic Matter} + \text{Ce}^{4+} + \text{HOBr} \rightarrow \text{Br}^- + \text{Ce}^{3+} + \text{Bromated Organic Matter} + \text{Oxidized Organic Matter}$, which in turn will refuel the Bromide reaction. This oscillatory reaction process may also create an anolyte migratory WAVE pattern (i.e., periodic mass-transport). Additionally, the exothermic portion of the described reactions will in turn also describe a temporal and spatial oscillatory process, called a THERMOKINETIC OSCILLATOR. Metabolic processes such as the formation of ATP and concurrent depletion of ADP are spatially confined by the MEMBRANE processes, imposing spatial constraints on the reaction process, which in turn leads to oscillatory reaction processes in time as well as space.

Oscilloscope

[general] Device used to display time-varying signals by diverting an electron beam (CATHODE ray) in the vertical direction based on the MAGNITUDE of the SIGNAL strength, while the horizontal axis is a time frame reference. The oscilloscope uses a VACUUM tube with a cathode-based electron gun and horizontal and vertical deflection plates that are electrically charged by external potentials. The electron beam is targeting a fluorescent screen that writes the time-dependent AMPLITUDE for visual interpretation (see Figure O.46).

(a)

(b)

(c)

Figure O.46 (a–c) Oscilloscope.

Osmolality

[biomedical, chemical] Measure of the moles or osmoles (molar concentration of individual SOLUTE particles) of constituent solute per kilogram of SOLVENT medium expressed as (mol/kg, or molal). Note this compares to osmolarity by conversion of kilograms to liters.

Osmolarity ($\Sigma[C_i]$)

[biomedical, chemical] Sum of the molar concentrations ($[C_i]$) of dissolved solutes (measure of osmoles of solute per liter of SOLVENT medium), considering the partial pressures of the individual constituents: $\Sigma[C_i]$. When the solute concentration exceeds the EQUILIBRIUM STATE or the concentration assessed at the starting point, the FLUID becomes hyperosmotic. When the loss of electrolytes exceeds the loss of solvent, the SOLUTION becomes hypoosmotic. When the situation at the beginning and end are equal in osmotic value, although the absolute quantity need not be preserved, the solution is isosmotic or ISOTONIC. This also applies to two solutions in equilibrium across a SEMIPERMEABLE MEMBRANE. Ionic compounds, such as salts, in solution will generally dissociate into their constituent ions, thus giving the osmolarity of the two dissolved constituent. In contrast, the molarity of the solution is based on the base compound, the joint components of the dissociated solute.

Osmole

[biomedical, chemical] Molar concentration of individual SOLUTE particles.

Osmosis

[biomedical, chemical, thermodynamics] “Active” transfer of SOLVENT through a MEMBRANE (most notably SEMIPERMEABLE MEMBRANE) based on a difference in concentration of a variety of solutes. The FLUID transfer (FLOW and FLUX) for osmosis is generally faster than regular DIFFUSION. Specifically in biological

applications, the osmotic transfer of interstitial fluid across the CELL MEMBRANE relies on gates that will open, or open wider under the influence of a CHEMICAL GRADIENT across the BARRIER (see Figure O.47).

Figure O.47 (a,b) Osmosis.

Osmotic coefficient (Φ_{osm})

[biomedical, fluid dynamics] Quantity that provides a characterization of the deviation from ideal behavior for a SOLVENT, as defined by **RAOULT'S LAW**, defined with respect to **OSMOLALITY** as $\Phi_{\text{osm}} = (\mu_A^* - \mu_A) / (RTM_A \Sigma[C_i])$, where μ_A is the chemical potential of the solvent in the SOLUTION, μ_A^* is the chemical potential of the solvent, M_A is the **MOLAR MASS**, $R = 8.3144621(75) \text{ J/Kmol}$ is the **GAS constant**, $\Sigma[C_i]$ is the **osmolarity**, and T is the temperature (in Kelvin). The osmotic coefficient (based on molality) is related to the **Gibbs free ENERGY** ($G(T, V, N)$), in this case available in excess to a stationary (ideal solvent) condition, as $RT(1 - \Phi_{\text{osm}}) = G_{\text{excess}} - \Sigma[C_i](dG_{\text{excess}}/d[C_i])$.

Osmotic pressure

[thermodynamics] Solute pressure that is a direct function of the **OSMOLALITY** ($\Sigma[C_i]$) of a solution: $\Pi = \Sigma[C_i]RT$, where T is the **TEMPERATURE** and $R = 8.3144621(75) \text{ J/Kmol}$ the **GAS constant**.

The net osmotic pressure across a SEMIPERMEABLE MEMBRANE will directly depend on the net cumulative concentration difference across the MEMBRANE (see [Figure O.48](#)).

Figure O.48 Osmotic pressure.

Osmotic pressure (Π_{osm}), Van't Hoff relation for

[fluid dynamics, thermodynamics] Chemical pressure associated with the concentration of a SOLUTE in a SOLVENT, with respect to the individual solutes, each providing a partial pressure that resembles the partial pressure for a GAS. The osmotic pressure (Π_{osm}) is a function of the number of ions that result from the dissociation of the solute (i), the concentration of the SOLUTE ($[\text{Solute}]$), and the OSMOTIC COEFFICIENT (ϕ_{osm}) indicating the mobility of the solute: $\Pi_{\text{osm}} = i\phi_{\text{osm}}[\text{Solute}]RT$, where T is the ABSOLUTE TEMPERATURE and $R = 8.3144621(75) \text{ J/Kmol}$ is the universal gas constant. Osmotic pressure influences the boiling point of a LIQUID as well as the FREEZING point. The osmotic pressure of a SOLUTION can be derived from the freezing point depression (ΔT_f) based on $i\phi_{\text{osm}}[\text{Solute}] = \Delta T_f / 1.86$. When two solutions are separated by a SEMIPERMEABLE MEMBRANE, the balance can be iso-osmotic for identical osmotic pressure and hence no DIFFUSION, or alternatively higher on side 1 (arbitrary, generally outside, vs. inside [2]): hyperosmotic, or reduced pressure on the outside: hypoosmotic.

Ossicles

[biomedical] The three critical mechanical components in the human MIDDLE EAR responsible for the HEARING process, connecting the tympanic MEMBRANE to the oval membrane on the cochlea by means of the hammer (malleus), anvil (incus), and stirrup (stapes) (see [Figure O.49](#)).

Figure O.49 The ossicles of the middle ear.

Osteoblast

[biomedical, mechanics] Large cell in bone responsible for the synthesis and mineralization of bone formation. The function of the OSTEOLAST persist from initial bone formation to bone remodeling in regenerative processes. Osteoblasts are part of a closely packed sheet of cells close to the external surface of the bone. Osteoblasts are “activated” by mechanical strain. The osteoblast will attempt to reinforce the bone where the strain may have the highest risk for crack formation (i.e. mechanical healing action) (see [Figure O.50](#)).

Figure O.50 (a) Osteoblast in osteon of (b) bone formation.

Osteoclast

[biomedical] Large cell in bone that is responsible for the resorption of bone cells that are nearing the end of their useful life span as part of the continuous regeneration process. Osteoclasts are spread throughout the bone. An osteoclast performs a function in bone remodeling in response to applied strain Osteoclasts are descended from stem cells (see [Figure O.51](#)).

Figure O.51 Osteoclast.

Ostwald, Dilution law

[atomic, general, quantum] See **DILUTION LAW OF OSTWALD**.

Ostwald, Wilhelm (1853–1932)

[chemical, solid-state, quantum] A chemist from Germany whose work contributed to the ion-theory published by SVANTE AUGUST ARRHENIUS (1859–1927) (see [Figure O.52](#)).

Figure O.52 Wilhelm Ostwald (1853–1932).

Otto, Nikolaus August (1832–1891)

[mechanics, thermodynamics] An engineer from Germany, or the Prussian Empire at the time. He is the inventor of the first INTERNAL-COMBUSTION ENGINE using the four-stroke mechanism of intake through the intake VALVE (increasing volume), compression, combustion with the use of a spark-plug—followed by EXPANSION and forced movement of the piston, and the final stroke pushing the exhaust fumes out through the exit valve) with the use of a piston transferring the ENERGY into work (see [Figure O.53](#)).

(a)

(b)

(c)

Figure O.53 (a) Nikolaus August Otto (1832–1891) and (b,c) Otto internal combustion principle for a V-8 engine.

Otto cycle

[thermodynamics] Idealized thermodynamic cycle representing the mechanism of action of a four-stroke INTERNAL COMBUSTION ENGINE, operating by means of spark ignition, as found in a reciprocating piston engine. The importance of the Otto cycle is the prevalence of this thermodynamic cycle in automobile engines. The process is named after NIKOLAUS AUGUST OTTO (1832–1891), who described the operations of the four-stroke engine in 1876. The efficiency of an ideal Otto cycle is described by the ratio of work performed to the heat input: $\eta_{\text{eff}} = (\text{work}/\text{heat input}) = (Q_H + Q_L)/Q_H = 1 + (1/r_{\text{comp}}^{\gamma_{\text{PV}} - 1})$, where Q_L is the loss of heat due to the exhaust of warm fluid, Q_H is the combustion heat, $r_{\text{comp}} = V_1/V_2$ is the compression ratio comparing the cylinder volume at the end of intake (V_1) to the volume under compression (reached primarily just after combustion; combustion in modern engines is several degrees before the top position of the cylinder), and the coefficient γ_{PV} represents the adiabatic process in the PV diagram: $T_4V_1^{\gamma_{\text{PV}} - 1} = T_3V_2^{\gamma_{\text{PV}} - 1}$ and $T_1V_1^{\gamma_{\text{PV}} - 1} = T_2V_2^{\gamma_{\text{PV}} - 1}$ (see Figure O.54).

Figure O.54 Otto cycle: (a) ideal and (b) actual.

Outer ear

[general] The EAR canal extending to the open AIR along with the external ear shell, connecting with the MIDDLE EAR at the tympanic MEMBRANE, further transferring the mechanical (acoustic) ENERGY by means of the OSSICLES to the INNER EAR (see [Figure O.55](#)).

Figure O.55 (a,b) Outer ear anatomy and (c) reference to middle and inner ear.

(Continued)

Figure O.55 (Continued) (d) reference to middle and inner ear.

Overtone

[acoustics, general] Waves emitted in addition to the FUNDAMENTAL FREQUENCY; the first overtone equates to the second harmonic (*see* HARMONICS).

Oxidation

[biomedical, chemical] EXOTHERMIC REACTION that combines (oxidation) oxygen with respect to another CHEMICAL COMPOUND. The process of oxygen removal is generally endothermic and is referred to as “reduction.” Oxidation of carbohydrates and fossil fuels will generally result in the formation of water and carbon dioxide under the oxidation and combustion processes. A chemical reaction that involves changing the oxygen binding (oxidation) process is referred to as a “REDOX REACTION.” More generally, a redox reaction pertains to the electron transfer between species. For example, combining oxygen and hydrogen forming water pertains to the fact that oxygen is reduced and hydrogen is oxidized. Another example of an oxidation reaction is the combining of hydrogen and fluorine: $H_2 + F_2 \rightarrow 2HF$.

Oximeter

[biomedical, optics] *See* PULSE OXIMETER.

Oxygen [^{16}O , O_2]

[biomedical, chemical, general] Chemical ELEMENT that is used in conversion of chemical elements to form ENERGY. The Earth's ATMOSPHERE consists of approximately 20.95% oxygen at sea level, less at greater altitudes. Oxygen in the UNIVERSE as we currently know is presumably the third most prevalent chemical, after hydrogen and helium. In biological units, oxygen forms a significant component of the following chemical compounds: carbohydrates, fats, nucleic acids, and proteins. In inorganic media, oxygen is part of the following chemical

structures: silicon dioxide (silica, found most prominently as quartz), water, and many oxides. Note that most METAL oxides are transparent, whereas under environmental conditions generally a hydroxide is formed, including both hydrogen and oxygen. Oxygen was discovered around 1773 by Swedish chemist CARL WILHELM SCHEELLE (1742–1786), and independently by English theologian and chemist JOSEPH PRIESTLEY (1733–1804) in 1774, and potentially by French chemist ANTOINE-LAURENT DE LAVOISIER (1743–1794) in 1778, who ultimately named it. Oxygen liquefies at 90.20 K and turns solid at 54.36 K (see Figure O.56).

Figure O.56 (a) Oxygen and its relation to ozone and (b) biological oxygen transportation through uptake by hemoglobin in the lung and release in tissue partially regulated by osmotic pressure.

Oxygen sensor

[biomedical, chemical] A sensor that measures the quantity of oxygen as either relative or absolute. Oxygen sensors are used to measure the reaction process of chemical events. A specific application is found in automobiles to regulate the fuel-oxygen mixture for high efficiency combustion, also referred to as “Lambda sensor.”

Ozone, [O_3]

[biomedical, chemical, general] Inorganic molecule with scientific name: $1\lambda^1, 3\lambda^1$ – trioxidane, also named μ – oxidodioxygen. Unstable allotrope of the ELEMENT oxygen, compared to the diatomic allotrope O_2 , discovered in 1865 by Swiss chemist JACQUES-LOUIS SORET (1827–1890). Condensation point is 161 K and MELTING POINT is 80 K (see Figure O.57).

Figure O.57 (a) Ozone gas (NPT, normal pressure and normal temperature) and (b) formation process.

 McMillan, Edwin Mattison (1907–1991), [463](#)
 Occhialini, Giuseppe (“Beppo”) Paolo Stanislaò
 (1907–1993), [205](#), [518](#), [518f](#)
 Young, John Zachary (1907–1997), [33](#)
 Lineweaver, Hans (1907–2009), [264](#)
 Landau, Lev Davidovich (1908–1968), [184](#), [184f](#)
 Alfvén, Hannes Olof Gösta (1908–1995), [317](#)
 Kurti, Nicholas (1908–1998), [304](#)

- Teller, Ede (Edward) (1908–2003), [96](#), [174](#)
 Land, Edwin Herbert (1909–1991), [183](#), [183f](#)
 Monod, Jacques Lucien (1910–1976), [408](#), [408f](#)
 Koopmans, Tjalling Charles (1910–1985), [151](#)
 Shockley, William (1910–1989), [111](#)
 Obert, Edward F. (1910–1993), [515–516](#), [516f](#)
 Hodgkin, Dorothy Mary (1910–1994), [33](#), [33f](#)
 Chandrasekhar, Subrahmanyan (1910–1995), [168](#)
 Goldman, David E. (1910–1998), [119](#), [353](#)
 Goldman, S. (1910–1998), [355](#)
 Kerst, Donald William (1911–1993), [126](#), [126f](#)
 Nier, Alfred Otto Carl (1911–1994), [477](#), [477f](#)
 Katz, Bernard, Sir (1911–2003), [119](#), [119f](#), [353](#), [355](#)
 Wheeler, John Archibald (1911–2008), [268](#)
 Kolff, Willem Johan (1911–2009), [2](#), [148–149](#), [149f](#), [244](#)
 Retherford, Robert (1912–1981), [176](#)
 Junge, Christian (1912–1996), [111](#), [112f](#)
 Purcell, Edward Mills (1912–1997), [312](#)
 Seaborg, Glenn T. (1912–1999), [463](#)
 Philbrick, George A. (1913–1974), [529](#)
 Kaplan, Irving (1913–1997), [117](#), [117f](#)
 Abelson, Philip Hauge (1913–2004), [463](#)
 Lamb, Willis Eugene (1913–2008), [50](#), [174–176](#), [174f](#)
 Hodgkin, Alan Lloyd, Sir (1914–1998), [32–33](#), [32f](#), [44](#),
 [119](#), [353](#), [355](#)
 Lamarr, Hedy (1914–2000), [172–173](#), [173f](#)
 Abramowitz, M. (1915–1958), [96](#)
 Townes, Charles Hard (1915–2015), [192](#), [330](#)
 Kittel, Charles (1916–), [141](#), [141f](#)
 Gordon, Solon A. (1916–1973), [282](#)
 Marshak, Robert Eugene (1916–1992), [329–330](#), [329f](#)
 Shannon, Claude Elwood (1916–2001), [513](#)
 Prokhorov, Aleksandr M. (1916–2002), [330](#)
 Brown, Harrison Scott (1917–1986), [117f](#)
 Wahl, A. C. (1917–2006), [463](#)
 Lorenz, Edward Norton (1917–2008), [277–279](#), [278f](#)
 Huxley, Andrew Fielding, Sir (1917–2012), [32–33](#), [44](#),
 [44f](#), [119](#)
 Feynman, Richard Phillips (1918–1988), [322](#), [329](#)
 Jost, Res (1918–1990), [105](#)
 Reines, Frederick (1918–1998), [469](#)
 Skeggs, Leonard T., Jr. (1918–2002), [149](#), [244](#)
 Kaufmann, William Weed (1918–2008), [119](#)
 Cowan, Clyde (1919–1974), [469](#)
 Leonards, Jack Rack (1919–1978), [149](#), [244](#)
 Nomarski, Georges (Jerzy) (1919–1997), [487](#), [487f](#)
 Knight, Walter David (1919–2000), [143–144](#), [144f](#)
 Stegun, I. A. (1919–2008), [96](#)
 Gould, Gordon (1920–2005), [192](#), [321](#)
 Corso, John F. (1920–2013), [520](#)
 Jacob, François (1920–2013), [408](#)
 Kill, Fredrick (1921–), [129](#), [129f](#)
 Schawlow, Arthur Leonard (1921–1999), [192](#), [330](#)
 Kline, Stephen Jay (1922–), [141](#)
 Basov, Nicolay G. (1922–2001), [330](#)
 Jefimenko, Oleg Dmitrovich (1922–2009), [97–98](#), [97f](#)
 Anderson, Philip Warren (1923–), [425](#)
 Kohn, Walter (1923–), [148](#), [148f](#)
 Pitts, Walter Harry (1923–1969), [465](#)
 Lattes, César Mansueto Giulio (1924–2005), [205–206](#),
 [206f](#), [518](#)
 Bell, George Irving (1926–2000), [438](#)
 Maiman, Theodore Harold (1927–2007), [192](#), [321](#), [321f](#)
 Brout, Robert (1928–2011), [28](#)
 Higgs, Peter Ware (1929–), [28](#), [28f](#)
 Moore, Earle Gordon (1929–), [415](#), [415f](#)
 Lauterbur, Paul Christian (1929–2007), [210](#),
 [210f](#), [312](#)
 Mössbauer, Rudolf Ludwig (1929–2011), [422](#)
 Kondo, Jun (1930–), [150](#), [150f](#)
 Englert, François (1932–), [28](#)
 Kibble, Thomas Walter Bannerman, Sir (1932–), [28](#)
 Bartlett, Neil (1932–2008), [481](#)
 Ernst, Richard Robert (1933–), [210](#)
 Hopfield, John Joseph (1933–), [465](#)
 Mansfield, Peter, Sir (1933–), [312](#)
 Vallbo, Åke Bernhard (1933–), [347](#)
 Welch, Ashley J. (1933–2009), [282](#)
 Bonner, Francis (1934–), [117f](#)
 Presley, Elvis (1935–1977), [511](#)
 Guralnik, Gerald Stanford (1936–2014), [28](#)
 Hagen, Carl Richard (1937–), [28](#)
 Pohl, Dieter Wolfgang (1938–), [454](#)
 Josephson, Brian David (1940–), [104–105](#), [104f](#)
 Bopp, Thomas (1949–), [4](#)
 Johansson, Roland S. (1950–), [347](#)
 Denk, W. (1957–), [454](#)
 Hale, Alan (1958–), [5](#)

Index of Subjects

Note: Page numbers followed by f and t refer to figures and tables, respectively.

Acoustics

- Harmonic motion, 9, 9f
- Hearing, 13–14, 14f
- Helmholtz, Hermann Ludwig Ferdinand von (1821–1894), 20–21, 21f
- Helmholtz energy, 22
- Helmholtz resonator, 22
- Hertz, Heinrich Rudolf (1857–1894), 26, 26f
- Image, 56–57, 57f
- Impedance (Z), 59, 59f
- Impulse response, 61–62, 62f
- Infrasound, 68
- Interference, 73, 73f
- Inversion, 78–80, 79f–80f
- Kadomtsev–Petviashvili equation, 116
- Kirchhoff radiation integral, 137
- Knife-edge detector, 143
- Korotkoff sounds, 153, 154f
- Korotkov, Nikolai Sergeyevich (Николай Сергеевич Коротков) (1874–1920), 154–155, 155f
- Korteweg–de Vries equation, 155
- Krimholtz–Leedom–Matthaei (KLM) transducer model, 159
- Lamb, Horace, Sir (1849–1934), 174, 174f
- Lamb, Willis Eugene (1913–2008), 174, 174f
- Lamé coefficient, 179–180, 180f
- Langevin, Paul (1872–1946), 185–186, 186f
- Langevin equation, 186
- Langevin formula, 186
- Lateral resolution, 203–204
- Lattice vibration, 208, 208f
- Law of reflection, 216
- Law of refraction, 216
- Lead zirconate titanate (PZT), 224–225, 225f
- Lens, 235–236, 236f
- Lens aberrations, 240–241, 241f
- Linear absorption coefficient (μ_a), 261
- Linear attenuation coefficient, 262
- Linear beamforming, 262
- Linear filter, 262
- Liouville, Joseph (1809–1882), 264–265, 265f
- Lippmann–Schwinger integral, 266
- Longitudinal cusp caustic, 273, 273f
- Loudspeaker, 281, 281f
- Mach, Ernst (1838–1916), 293, 293f
- Mach angle, 293–294, 294f
- Mach cone, 295, 295f
- Mass–spring system, 334–335, 335f
- Matter wave, 338, 338f
- Mersenne, “father” Marin (1588–1648), 360–361, 361f
- Method of moments, 369–370
- Metrology, 371
- Michelson, Albert Abraham (1852–1931), 372, 372f
- Michelson interferometer, 372–373, 373f
- Microelectronic-mechanical systems (MEMS), 374, 374f
- Microphone, 375–376, 376f
- Minimum mean square error, 388
- Minimum phase filter, 389
- Mini-sparker, 389
- Mode conversion, 394
- Moiré pattern, 397, 397f
- Molding stresses, 398
- Motional feedback loudspeaker, 424, 424f
- Multiparameter inversion, 426–427
- Myotis pulse, 442, 442f
- Natural angular frequency, 447, 447f–448f
- Natural frequency, 449, 449f
- NDE, 452
- Nearest-neighbor interpolation, 453
- Nearfield acoustic holography, 453–454, 454f
- Niobium, 477
- Noise, 485–486, 486f
- Nondispersive wave, 490, 490f
- Numeric evaluation, 509
- Oblique angle scanning, 516–517, 517f
- Octave, 520, 520f
- Octave Stretching, 520
- Organ of Corti, 545, 545f
- Oscillating spring, 548–549, 549f–550f
- Overtone, 564
- Astronomy/Astrophysics
 - Hale, George Ellery (1868–1938), 4, 4f
 - Hale–Bopp comet, 5, 5f
 - Hale’s law, 5
 - Halley, Edmund (1656–1742), 7, 7f
 - Halley’s comet, 7

Astronomy/Astrophysics (*Continued*)

He4, 4Helium (^4He), 11
 Heliocentric, 19–20, 20f
 Heliographic latitude, 20
 Herschel, Friedrich Wilhelm (Frederick William), Sir (1738–1822), 24
 Hertzsprung–Russell diagram, 26–27, 27f
 Hipparchus (190–125 BC), 30–31, 31f
 Hubble, Edwin Powell (1889–1953), 38, 38f
 Hubble's law, 40
 Invariable plane, 78, 78f
 Jupiter, 112, 112f
 Kelvin–Helmholtz instability, 122–123, 123f
 Kelvin–Helmholtz relation, 123
 Kepler's laws, 124
 Kirkwood gap, 139–140, 140f
 Kottler, Friedrich (1886–1965), 157, 157f
 $L(\vec{r}, \vec{s}, t)$, 167–168, 168f
 La Systeme International d'Unites, 170
 Lagrange, (Joseph-Louis) Giuseppe Luigi comte de Lagrange (1737–1813), 170, 170f
 Landau–Darrius instability, 184–185, 185f
 Landau, Lev Davidovich (1908–1968), 184, 184f
 Lane–Emden equation, 185
 Laplace, Pierre-Simon de, Marquis de Laplace (1749–1827), 187–188, 188f
 Laws of planetary motion, 220
 Le Verrier, Urbain (1811–1877), 223, 223f
 Legendre differential equation, 229
 Legendre polynomial, 229–230
 Lemaître, Monseigneur Georges Henri Joseph Édouard (1894–1966), 232, 232f
 Lepton, 244
 Lepton number (L), 244
 Luminiferous ether, 287
 Luminosity function, 287, 287f
 Lunar tide, 288, 288f
 Maclaurin, Colin (1698–1746), 299, 299f
 Maclaurin ellipsoid, 299–300, 300f
 Magnet, 301–302
 Magnetic, 302, 302f
 Magnetic buoyancy, 303–304, 304f
 Magnetic north pole, 309–310, 310f
 Magnetism, 315
 Mariner, 326, 326f
 Mars, 328, 328f
 Mercury barometer, 360, 360f
 Meteor, 368, 368f
 Meteorite, 368
 Meteoroid, 369
 Mie absorption, 384
 Mie scattering, 384–385, 385f
 Milky Way, 385–386, 386f
 Möbius, August Ferdinand (1790–1868), 393, 393f
 Molniya orbit, 402–403, 403f
 Moon, 413–414, 414f

Morgan–Keenan luminosity classes, 416, 416f
 Motion, 423, 423f
 Muon, 428–429, 429f
 Neutron star, 471–472, 472f
 Nicholson, John Williams (1881–1955), 476
 Nier, Alfred Otto Carl (1911–1994), 477, 477f
 Northern Light, 497
 Nutation, 510–511, 511f
 Occhialini, Giuseppe (“Beppo”) Paolo Stanislaw, 518, 518f

Atomic Physics

H, 1
 H_2 problem, 1
 Haas, Arthur Erich (1884–1941), 1, 1f
 Hadron, 2
 Half thickness ($d_{1/2}$), 5
 Half-life ($\tau_{1/2}$), 6, 6f
 Hamiltonian operator, 8
 Harmonic oscillation, 10, 10f
 H-bomb, 10–11, 11f
 Health physics, 13, 13f
 Heisenberg, Werner Karl (1901–1976), 19, 19f
 Higgs, Peter Ware (1929–), 28, 28f
 Higgs boson, 28
 Higgs mechanism, 28
 Hull, Albert Wallace (1880–1966), 40–41, 41f
 Hund, Friedrich Hermann (1896–1997), 43
 Hund's law, 43
 Hund's rule, 44
 Huygens, Christiaan (1629–1695), 45, 45f
 Hydrogen atom, 47
 Hydrogen bomb, 47, 47f
 Hydrogen bond, 47, 47f
 Hyperfine constant, 49
 Hyperfine structure, 49–51, 50f–51f
 Hypernuclear physics, 51
 Identical particles, 56
 Indeterminacy principle, 62
 Infinite square well, 67
 Insulator, 71–72, 72f
 Interferometer, 73–75, 74f–75f
 Intermolecular forces, 75
 Internal conversion, 76–77, 77f
 Inversion, 78–80, 79f–80f
 Ion, 81
 Ion mobility, 82
 Ionization, 83, 83f
 Ionization energy, 84
 Ionosphere, 84, 84f
 Isomeric nuclei, 90
 Isomers, 90, 90f
 Isospin (I), 91–92
 Isotone, 93
 Isotope, 94, 94f
 j-j coupling, 101–102, 101f–102f
 Johnson noise, 102

- Junge power law, 111–112, 112f
K characteristic X-rays, 113
K meson, 113
K-alpha lines, 113, 113f
K-electron capture, 114
 Kaufmann, William Weed (1918–2008), 119
 Kaufmann and Bucherer experiments, 119
 Keesom, Willem Hendrik (Wilhelmus Hendrikus) (1876–1956), 120, 120f
 Keesom force, 121
 Kerst, Donald William (1911–1993), 126, 126f
 Klystron, 142, 142f
 Knipping, Paul (1883–1935), 144, 144f
 Kohlhörster, Werner Heinrich Gustav (1887–1946), 147, 147f
 Kohn anomaly, 148, 148f
 Kossel effect, 156, 156f
L characteristic X-rays, 169, 169f
 Lagrangian equations in generalized co-ordinates, 170
 Lamb, Willis Eugene (1913–2008), 174, 174f
 Lamb shift, 175, 175f
 Lamb–Retherford experiment, 176
 Lambda particle, 176
 Lambda point, 177, 177f
 Lande's *g*-factor, 185
 Langmuir, Irving (1881–1957), 186–187, 187f
 Langmuir probe, 187
 Laplace equation, 188
 Laporte, Otto (1902–1971), 189, 189f
 Laporte rule, 190
 Larmor, Joseph, Sir (1857–1942), 190–191, 191f
 Larmor frequency (ω), 191
 Larmor precession, 191, 191f
 Lattes, César Mansueto Giulio (1924–2005), 205–206, 206f
 Lattice, 206, 206f
 Lattice array, 206
 Lattice constant, 207, 207f
 Lattice factor, 207
 Lattice plane, 207, 207f
 Lattice spacing, 207
 Lattice vibration, 208, 208f
 Laue diffraction pattern, 209
 Laue technique, 210
 Lauritsen, Charles Christian (1892–1968), 210, 210f
 Law of conservation of parity, 214
 Lawrence, Ernest Orlando (1901–1958), 218, 218f
 Legendre transform, 230
 Lemaître, Monseigneur Georges Henri Joseph Édouard (1894–1966), 232, 232f
 Lenard, Philipp Eduard Anton von, 233
 Lepton, 244
 Lepton, angular momentum of, 244
 Lepton number (*L*), 244
 Line spectrum, 259–260, 260f
 Linear accelerators, 261, 261f
 Linear operator, 263
 Linear oscillator, 263, 263f
 Liquid crystal display (LCD), 267–268, 268f
 Liquid drop model, 268–269, 269f
 L-meson, 271
 Long-range alpha particles, 275
 Lorentz, Hendrik Antoon (1853–1928), 275–276, 276f
 Lorentz contraction, 276
 Lorentz equations, 276
 Lorentz transformation, 277
 Los Alamos National Laboratory, 279, 279f
 L–S Coupling, 284, 284f
 Lyman series, 290, 290f
 Lyman, Theodore (1874–1954), 290, 290f
 Magnetic cooling, 304–305, 305f
 Magnetic resonance, 311–312, 312f
 Magnetic susceptibility (χ_{mag}), 315
 Magnetron, 317
 Manhattan project, 322, 322f
 Marsden, Ernest (1889–1970), 328–329, 329f
 Marshak, Robert Eugene (1916–1992), 329, 329f
 MASER, 330, 330f
 Mass (*m*), 331
 Mass number (*A*), 333
 Mass spectrograph, 333
 Mass spectrometer, 333–334
 Mass spectroscopy, 334, 334f
 Mass transformation equation, 335
 Mayer, Maria Goeppert (Göppert) (1906–1972), 343, 343f
 McLennan, John Cunningham, Sir (1867–1935), 344, 344f
 Mean free path, 345, 345f
 Mean life (τ_{decay}), 345
 Meitner, Lise (1878–1968), 350, 350f
 Mendeleeev, Dmitri Ivanovich [Дмитрий Иванович Менделѣев] (1834–1907), 356–357, 357f
 Menzel, Donald Howard (1901–1976), 359, 359f
 Meson theory of nuclear forces, 362
 Metastable state (equilibrium), 367–368, 368f
 Michelson, Albert Abraham (1852–1931), 372, 372f
 Michelson interferometer, 372–373, 373f
 Michelson–Morley experiment, 373
 Microscope, resolving power, 380
 Mie scattering, 384–385, 385f
 Miller indices, 386, 386f
 Millikan oil-drop experiment, 387, 387f
 Millikan, Robert Andrews (1868–1953), 387, 387f
 Mirror nuclei, 390
 Moist air, 397
 Molar heat capacity (*c_m*), 397
 Mole, 398
 Molecular band, 398, 398f
 Molecular beam, 399
 Molecular heat, 399

Atomic Physics (*Continued*)

- Molecular spectra, 399
 - Molecular spectroscopy, 399–400, 400f
 - Molecule, 400–401, 401f
 - Momentum eigenfunction, 407
 - Monatomic gases, 407
 - Morse potential, 419–420, 420f
 - Moseley, Henry (Harry) Gwyn Jeffreys (1887–1915), 420–421, 421f
 - Moseley diagram, 421, 421f
 - Moseley's law, 422
 - Motion, 423, 423f
 - Multiplication factor, 427
 - Multiplicity of spectra, 427–428, 428f
 - Multiplier tube, 428
 - Muon, 428–429, 429f
 - N^{13} , $^{13}\text{nitrogen}$, 443

Fluid Dynamics

Hagen, Gotthilf Heinrich Ludwig (1797–1884),
2–3, 3f

Hagen–Poiseuille law, 3

Hamiltonian mechanics, 8

Harmonic motion, 9, 9f

Harmonic oscillation, 10, 10f

Head loss, 11, 11f

Head loss, Borda–Carnot, 12, 12f

Heart, 15, 15f

Helmholtz, Hermann Ludwig Ferdinand von
(1821–1894), 20–21, 21f

Helmholtz decomposition, 22

Henry, William (1774–1836), 23, 23f

Henry's law, 23–24

Herschel, Friedrich Wilhelm (Frederick William), Sir
(1738–1822), 24

Herschel–Bulkley coefficient of friction, 24

Herschel–Bulkley fluid, 24–25, 25f

Herschel–Bulkley yield stress (σ_{yield}), 25–26

Hodgson number ($H = fV\Delta P/Q\bar{P}$), 34

Hydraulic impedance, 46

Hydraulics, 46, 46f

Hydrology, 48

Hygrometer, 49, 49f

Hysteresis, 52, 52f

Ideal fluids, 54

Ideal gas, 54

Image, 56–57, 57f

Implicit approximate factorization method, 60

Incompressible fluid, 62

Inspiratory capacity, 69–70, 70f

Inspiratory reserve volume, 71

Internal energy (U), 77

Inviscid flow, 81

Irrotational flow, 85

Irrotational (curl-free) vector field, 85

Isaac Newton (1642–1727), 85

Isentropic, 85

Isentropic flow, 86, 86f

Isoobaric change, 88

Isochoric process, 89

Jacobi's ellipsoids, 96

Jet, 99, 99f

Jet force, 99

Jet plane, 100, 100f

Jet theory for capillary phenomena, 100, 100f

Joukowski's hypothesis, 105

Joukowski, Nikolay (1847–1921), 106

Joukowski equation, 106

Journal bearing, 108–109, 109f

Junge power law, 111–112, 112f

k -Epsilon model, 114

Kadomtsev–Petviashvili equation, 116

Kármán eddy current vortex street, 118, 118f

Kármán, Theodore von (1881–1963), 118, 118f

Kelvin's circulation theorem, 122

Kelvin's theorem of minimum energy, 122, 122f

Kelvin–Helmholtz instability, 122–123, 123f

Kelvin–Helmholtz relation, 123

Keulegan–Carpenter number (K_c), 127

Kidney, 128, 128f

Kinematic coefficient of viscosity (μ_k), 130, 130f

Kinematic viscosity, 130

Kinetic energy of a solid moving through a
liquid, 133–134

Kinetic stability, 135

Kinetostatics, 136, 136f

Kirchhoff radiation integral, 137

Kline bursting phenomenon, 141–142, 142f

Knudsen, Martin Hans Christian (1871–1949),
144–145, 145f

Knudsen number ($Kn = \lambda/L$), 145

Köhler curve, 146, 146f

Köhler equation, 146

Köhler theory, 146

Kolff, Willem Johan (1911–2009), 148–149, 149f

Korotkoff sounds, 153, 154f

Korotkov, Nikolai Sergeyevich (Николай Сергеевич
Коротков) (1874–1920), 154–155, 155f

Korteweg–de Vries–Burgers wave equation, 155

Korteweg–de Vries equation, 155

Krogh tissue cylinder model, 160

Kutta, Martin Wilhelm (1867–1944), 164

Kutta condition, 164, 164f

Kutta–Joukowski equation, 165

Kutta lift, 165

La Systeme International d'Unites, 170

Lagrangian equations in generalized co-ordinates, 170

Lagrangian finite strain tensor, 170

Lagrangian form of the hydrodynamical equations, 171

Lamb, Horace, Sir (1849–1934), 174, 174f

Lamb wave, 175–176, 176f

Lamina, 180, 180f

Laminar boundary layer, flat plate, 181

Laminar flow, 181, 181f

Laminar flow, pipes, 181–182, 182f

Laminar frictional resistance, 182

Laminar sublayer, 182, 182f

Landau, Lev Davidovich (1908–1968), 184, 184f

Landau–Darrieus instability, 184–185, 185f

Laplace equation, 188

Laplace law, 188–189, 189f

Large Eddy simulation (LES), 190, 190f

Laser Doppler, 200, 200f

Laser Doppler anemometer, 201

Laser holographic interferometer method,
201, 201f

Laval nozzle, 211, 211f

Law of conservation of energy, 213–214

Law of corresponding states, 214

Law of Pascal, 216

Preface

The purpose of this *encyclopedia* is to provide a single, concise reference that contains terms and expressions used in the study, practice, and applications of physical sciences. The reader will be able to quickly identify critical information about professional jargon, important people, and events. This encyclopedia gives self-contained definitions with essentials regarding the technical terms and their usages and information about important people in the following areas of physics:

- Acoustics
- Astronomy/astrophysics
- Atomic physics
- Biomedical physics
- Chemical physics
- Computational physics
- Condensed matter
- Dynamics
- Electromagnetism
- Electronics
- Energy
- Engineering
- Fluid dynamics
- General
- Geophysics
- High-energy physics
- Imaging
- Instrumentation
- Materials sciences
- Mechanics
- Meteorology
- Nanotechnology
- Nuclear physics
- Optics
- Quantum physics
- Relativistic physics
- Rheology
- Sensing
- Signal processing
- Solid-state physics
- Theoretical physics
- Thermodynamics
- Ultrafast phenomena

This reference differs from the standard dictionaries in its inclusion of numerous illustrations, including photographs, micrographs, diagrams, graphs, and tables, which support the textual definitions and draw the reader into the explanation to enhance didactic value. Together, these over 2500 entries will educate the reader about the current practice of physics and its applications in biomedicine, materials sciences, chemical engineering, electrical engineering, mechanical engineering, geology, astronomy, meteorology, and energy.

It is envisioned that novices and trainees, in addition to seasoned professionals, will find this resource useful, both for sustained reading and for taking a dip into the topics periodically. The contents are also designed to help the professionals who are new to a work environment and recently enrolled students who need to become more familiar with terminology and nuances relevant to certain research and applications. Moreover, it will assist in understanding the primary literature as well as technical reports and proposals. Finally, any student from the high school to graduate levels should be able to benefit from the broad and applied emphasis of this concise encyclopedia, which may support undergraduate courses in applied sciences for nonscience majors.

Author

Robert Splinter, PhD, obtained his master of science degree in applied physics from the Eindhoven University of Technology, Eindhoven, the Netherlands, and his PhD from the VU University of Amsterdam. Dr. Splinter built his career as a scientist and technology manager in biomedical engineering. His work is dedicated to resolving issues in device development with a particular focus on medicine and biology through the development of novel diagnostic techniques and treatment methods using all multidisciplinary aspects of engineering and applied physics.

He cofounded several companies in biomedical engineering and worked for several established metrology and medical device companies. In addition, Dr. Splinter worked in clinical settings, prototyping, and validating devices using the full practical and theoretical knowledge of physics, engineering, electrical engineering, chemistry, and biology. He is an associate professor (Adj.) in the Department of Physics at the University of North Carolina at Charlotte.

P

***p* (linear momentum)**

[general, mechanics] $p = mv$, where m is the mass of the object in MOTION with velocity v (see MOMENTUM).

Pacemaker

[biomedical] Biological or electronic unit providing the excitation mechanism that induces a self-sustained DEPOLARIZATION process in the HEART muscle. The biological unit in mammals is located in the atrium and consists of a small group of cells with a range of natural depolarization periods, presumably based on a cellular ionic leak that eventually generates a full cellular depolarization, generating an impulse that is transmitted to neighboring MUSCLE cells that will respond to the threshold exceeding voltage spike. Various cells have specific depolarization rates, thus allowing for a regulation mechanism of the heart rate. The depolarization rate can be influenced externally in limited amount by the autonomic nerve system and by hormonal influences. The artificial pacemaker is an electronic device that generates an electrical pulse that is conducted to the heart muscle by means of electrodes and is powered by a BATTERY. Artificial pacemakers have evolved of time from fixed rate to on demand. Additionally, bioelectricity is being investigated to power modern pacemakers, eliminating the need for surgical battery replacement. The on-demand pacemaker “measures” ACTIVITY and regulates the emission rate of the current spikes to longer or shorter intervals. The pacemaker’s purpose is the general BLOOD supply to the body and brain as well as mitigation of external influences to maintain HOMEOSTASIS and accommodate the efficiency of the organs with respect

to their particular functions. Artificial pacemakers are a major economic force in medical device design (see [Figure P.1](#)).

Figure P.1 Image of artificial pacemaker.

Packing fraction

[nuclear] The difference between the ATOMIC WEIGHT in nuclear mass units (standard atomic weight: M_a) and the mass number of an ELEMENT (A), divided by the mass number, multiplied by 10,000. Packing fraction = $\left[(M_a - A) / A \right] \times 10,000$. Packing fraction is used as an indicator of nuclear stability.

Pair annihilation

[atomic, nuclear] See ANNIHILATION.

Pair formation

[nuclear] The formation of an elementary PARTICLE and its antiparticle. The creation process involves the application of a trigger phenomenon (generally a BOSON; e.g., PHOTON) with high enough ENERGY to accommodate the formation of two particles that balance the energy in REST MASS and movement (i.e., kinetic energy content). Since the CONSERVATION LAWS apply, the two particles shall respectively have the inverse properties. The passage of gamma rays with energy greater than or equal to 1.022 MeV in the proximity of the atomic NUCLEUS of certain ELEMENTS will generate an electron and a positron pair. This process was first described by PAUL ADRIEN MAURICE DIRAC (1902–1984) in 1928 basing his premonitions on relativistic wave-mechanics theory, and was subsequently observed by CARL DAVID ANDERSON (1905–1991) in 1932. In the atomic annihilation process, under the influence of positron RADIATION two gamma photons with 511 keV are produced that are emitted in perfect opposite directions ($\pm 5^\circ$). POSITRON EMISSION TOMOGRAPHY uses this principle for imaging purposes. Another kind of pair formation is found in support of SUPERCONDUCTIVITY

called a “COOPER PAIR,” consisting of two electrons (*see* COPPER PAIR and POSITRON EMISSION TOMOGRAPHY) (*see* Figure P.2).

Figure P.2 (a–d) Process of photon pair formation in positron emission tomography.

Pairing energy (P_{pair})

[atomic, nuclear] In the event of the pairing of electrons, the SPIN pairing ENERGY refers to the energy required to accommodate two paired electrons to share one orbital and what the effects are on the molecules surrounding this orbit. The electron–electron interactions must be taken into account, which involves Hund’s rule and PAULI EXCLUSION PRINCIPLES. For instance, Hund’s rule predicts for $d^1 - d^3$ systems that the electrons will not pair and occupy the t_{2g} -set spin configuration. The electron configuration will largely depend on the difference between the pairing energy (P_{pair}) and the electron gap energy (Δ_0), providing a higher spin configuration energy when the pairing energy exceeds the electron band-gap. The pairing energy is expressed in cm^{-1} .

Paleomagnetism

[astrophysics/astronomy, energy, geophysics] Study of the historical development and evolution of the Earth’s MAGNETIC field as permanently recorded in rocks, bricks, or clay. This study has revealed that the Earth’s magnetic field has changed direction (North–South) on the order of every several thousand years on a regular basis over the history of the EARTH. The Earth’s magnetic axis (magnetic North–South) can be described as having a “declination:” indicating the direction of MAGNETIC NORTH POLE with respect to the GEOGRAPHIC north pole; respectively “inclination:” the DISTANCE of the MAGNETIC AXIS to the geographic north pole.

$$\sin \lambda_p = \sin \lambda_\delta \cos p + \cos \lambda_\delta \sin p \cos D$$

$$\Phi_p = \Phi_s + \beta; \text{ for } \cos p > \sin \lambda_\delta \sin \lambda_p$$

$$\Phi_p = \Phi_s + 180 - \beta; \text{ for } \cos p < \sin \lambda_\delta \sin \lambda_p$$

where $\sin \beta = \sin p \sin D / \cos \lambda_p$. Additional information obtained shows that the MAGNETIC POLES are generally wandering, disturbing the presumed fixed MAGNETIC FIELD lines across the globe, thus influencing the global position through magnetic compass and guidance systems (see MAGNETIC POLE and MAGNETIC DRIFT) (see Figure P.3).

(a)

(b)

Figure P.3 (a) Documented drift of South Pole over the past ~250 million years (b) Illustration of the concept and study of paleomagnetism.

Papin, Denis (1647–1712)

[general, mechanics, thermodynamics] French physicist and mathematician. Forerunner of the concept of the steam ENGINE with his invention of the concept of the PRESSURE COOKER also called a digester. The ideas of Papin inspired THOMAS SAVERY (1650–1715) to pursue his collaborative efforts in the development of the steam engine (see Figure P.4).

Figure P.4 Denis Papin (1647–1712) in 1689.

Parabola

[biomedical, computational] Symmetric graphical representation of a variety of mathematical expressions, but the most well known is the quadratic equation, for instance, mathematically expressed as $y = ax^2 + bx + c$, or $x = y^2$, respectively, in general notation: $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$, where x and y are CARTESIAN COORDINATES and the remaining letters are constants. The parabola has an axis of symmetry that intersects with the graphical representation of the parabola in the vertex. The parabola is in the family of conic intersects: circle, ellipse, parabola, and hyperbola. In MECHANICS, the parabolic trajectory is well known and can be defined by the vector sum of the gravitational attraction and the propulsion force, where PROPULSION will be in vertical and horizontal directions. A horizontally released PROJECTILE (e.g., bullet from a gun) will have a vertical dependence on gravity (GRAVITATIONAL ACCELERATION g) as a function of time (t), describing only one side of the parabolic track defined as $y = -(1/2)gt^2$ (see Figure P.5).

Figure P.5 (a) Parabola graph and (b) parabolic antenna.

Paracrine signaling

[biomedical, chemical, energy, general] Cellular uptake of signaling molecules, known as paracrine factors. Form of cellular communication, aimed at modifying the behavior of neighboring cells, short DISTANCE interaction only. Generally, the molecular constituents are self-terminating and have a short-lived impact.

This type of communication takes place in the early stage of cellular development. The following four specific communication pathways/receptor mechanisms can be identified: fibroblast growth factor (FGF) family, hedgehog family, TGF- β superfamily, and Wnt family. The concession is that the FGF family stimulates proliferation and differentiation, the hedgehog family of receptors affects protein assembly and other cellular process and has been shown to be instrumental in certain aspects of the proliferation of cancer processes, the TGF- β superfamily influences POLYPEPTIDE secretion and regulates cellular development, and the Wnt family of receptors has been shown to affect gene transcription, as well as influence the ACTIN and microtubular cytoskeleton next to the effects on transmembrane receptor function and the inhibition, respectively, assimilation of specific proteins (see [Figure P.6](#)).

Figure P.6 Paracrine signaling function of prostacyclin hormone.

Parallel axis theorem

[general, mechanics] Theorem used to determine the moment of INERTIA of a rigid body about any axis, when the moment of inertia of the body about a parallel axis through the object's center of mass is known as well as the DISTANCE with respect to the perpendicular axes. Also known as the Huygens–Steiner theorem after the work of both the Dutch scientist CHRISTIAAN HUYGENS (1629–1695) and the Swiss mathematician Jakob Steiner (1796–1863). The MOMENT OF INERTIA (I) is now defined with respect to the distance between the off-center axis and the center of mass ($\square_{\text{cm}}$) axis, r , as $I = I_{\text{cm}} + mr^2$, where m is the mass of the object.

Parallel circuit

[general] Electrical components that are connected to operate in parallel to each other, groups of components that share at least one single common connection point. This stands in contrast to series circuits, where components operate in cascade. Electronic components are, for example, resistors, capacitors, inductors, diodes, transistors, operational amplifiers, and general INTEGRATED CIRCUITS (see [Figure P.7](#)).

Figure P.7 Schematic of four dry-cell batteries in parallel circuit configuration, providing the same voltage as each individual battery.

Parallel processing

[acoustics, computational, theoretical] Functional process of simultaneously performing multiple operations or tasks. Parallel processing is used both for human cognition and in parallel computing by MACHINES. The brain in particular has the ability to simultaneously process multiple incoming stimuli, and respond to all or most of them. Parallel processing in the human brain has for instance particular relevance to VISION, HEARING, and touch. For other species, this may extend to smell just as much. In vision, the brain divides observations into four components: COLOR, depth, MOTION, and shape. These four perceptions are analyzed individually and compared to reference memories, in order to identify the observations. The brain then recombines all of this information into one image that you visually recognize and comprehend. Parallel processing of the brain may be linked to what is referred to as the Stroop effect. The Stroop effect is a seamless operation that takes place on a continual basis. Computational parallel processing refers to having multiple algorithms work simultaneously, often splitting a program in its functional components. The computational processes will be run on individual separate electronic processors (central processing unit [CPU]). On a more elaborate level, several programs can run simultaneously in a single unit (i.e., computer) or on multiple computers electronically linked together in a cluster (cluster computing), which requires specialized software to function correctly, referred to as “distributed processing software.” Concurrency is a term used in communications for operating systems and databases referring to the condition where multiple tasks remain logically active and simultaneously advancing in the process by interleaving the execution order of the tasks. Concurrency actually merely creates the illusion of simultaneously executing instructions.

Parallel-plate capacitor

[electronics, general] Two charge carrying plates, with area A , separated by a fixed DISTANCE d , at opposite and equal charge (charge density σ_{charge}) form a CAPACITOR with capacitance $C = \epsilon_0 A/d$, where $\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{N m}^2$ is the permittivity of free space, which is altered when a medium is inserted with a different permittivity (ϵ), ignoring boundary effects. The electric field between the two plates is

$E = \sigma_{\text{charge}} / \epsilon_0$. Parallel-plate capacitors provided a popular tuning mechanism for analog RADIO operation (see CAPACITOR) (see Figure P.8).

Figure P.8 Electrolytic parallel-plate capacitor rolled up into tuning capacitor (variable parallel-plate capacitor) that adjusts the resonant frequency of a circuit by means of changing the surface area of the capacitor when turning the dial.

Parallel-plate fluid flow

[fluid dynamics] Two-dimensional LAMINAR FLOW process that will exhibit primarily the effects of shear stresses. The shear stress at the wall (τ) can be derived from the Navier–Stokes equations and the CONTINUITY EQUATION: $\tau = 6Q\eta_{\text{dyn}}/wb^2$, where the FLOW rate (Q) and plate separation or height (b) are the determining factors as is the width of the flow chamber (w), where η_{dyn} is the DYNAMIC VISCOSITY. The flow velocity v_x can be used to solve for the Navier–Stokes and continuity equations: $-(dP/dx) + \eta_{\text{dyn}}(\partial^2 v_x / \partial y^2) = 0$; $-(dP/dy) + \rho g_y$; $-dP/dz = 0$, where P is the pressure and g_y the GRAVITATIONAL ACCELERATION. The volume flow rate follows from POISEUILLE'S LAW and can be derived as the integral over the cross-sectional area: $Q = -w(2b^3/\eta_{\text{dyn}})(\partial P/\partial x)$. A special case is COUETTE FLOW, for instance relevant to LUBRICATION for a rotating axle in a housing (e.g., piston-bar on camshaft) (see Figure P.9).

Figure P.9 Parallel-plate fluid flow for an automated flow chamber assay.

Paramagnetic substances

[general] Magnetic material that under free space conditions has randomly oriented MAGNETIC dipoles, which can be aligned under the influence of an external MAGNETIC FIELD. The total magnetic field in the paramagnetic material under the influence of an external magnetic field ($\vec{B}_0$) is $B = B_0 + B_m = (1 + \chi)\mu_0 nI$, where $B_m = \chi B_0$ is the induced field with χ the magnetic susceptibility for the paramagnetic medium in case the external field is provided by a SOLENOID, I is the current, n is the number of windings, and $\mu_0 = 4\pi \times 10^{-7}$ H/m is the permeability of free space. For instance, for aluminum, $\chi_{Al} = 2.2 \times 10^{-5}$; for AIR, $\chi_{air} = 3.6 \times 10^{-7}$; and for water, $\chi_{water} = -9.12 \times 10^{-6}$.

Paramagnetism

[atomic, nuclear] The congruent lining up of the internal MAGNETIC FIELD within a solid body under the influence of exposure to an external magnetic field. The opposite is known as DIAMAGNETISM. Substances that have internal magnetic (DIPOLE) moment are sensitive to external magnetic fields as described by the MAGNETIC SUSCEPTIBILITY. The tendency of the internal magnetic dipoles to line up with an applied external magnetic field will generally be countered by the thermal agitation, which in turn continuously randomizes the individual magnetic dipoles. The partial alignment and resulting proportional increase in the total magnetic field was described by PAUL LANGEVIN (1872–1946).

Parametric acoustic array

[acoustics, computational] Directional transmitter and receiver configuration described based on WAVE propagation in an ideal FLUID that has no heat conduction and viscosity. The description involves nonlinear acoustical wave propagation described in accordance with the Lighthill equation as $(\partial^2 \rho / \partial t^2) - C_0^2 \nabla^2 \rho = -C_0^2 \square^2 \rho = (\partial^2 / \partial x_i \partial x_j) \mathbb{T}_{ij}$, where $\mathbb{T}_{ij} = \rho u_i u_j + P_{ij} - C_0^2 \rho \delta_{ij} + D_{ij}$ (D_{ij} the respective viscous stresses, P the pressure, i and j the reference frame directional subscripts (orthogonal), ρ the density, u the velocity, and C_0 a constant related to the acoustic AMPLITUDE) and $\nabla^2 = \nabla \cdot \nabla = \sum_{i=1}^n \partial^2 / \partial x_i^2$ is the Laplace operator. The collected “INTERFERENCE” pattern for the ACOUSTIC INTENSITY as a function of ANGLE (θ) is now relatively similar to the atomic RUTHERFORD SCATTERING, observed as the scattered (Δ_j) ANGULAR FREQUENCY $\omega_s = v_s 2\pi$, with v_s the acoustic frequency for a collimated beam with CROSS SECTION S_0 , retrieved from DISTANCE R_0 . The acoustic intensity distribution for the parametric array is described as $I_a = \omega_s^4 P_0^4 S_0^2 / 2 (8\pi)^2 \rho_0^3 C_0^9 \{1 + (1/2)(\rho_0 / C_0^2)(d^2 P / d\rho^2)_{\rho=\rho_0}\}^2 * \{1/R_0^2 [\alpha^2 + k_s^2 \sin^4((1/2)\theta)]\}$, where $\omega_s = \omega_2 - \omega_1$, with ω_1 the incident and ω_2 the re-emitted wave frequency; $k_s = \omega_s / C_0$; and $\alpha \sim$ scattering probability the “attenuation coefficient” (see ULTRASOUND) (see Figure P.10).

Figure P.10 Example of a parametric acoustic ultrasound imaging probe array.

Parasympathetic nerve system

[biophysics, chemical, energy] The human autonomic nerve system is divided into two distinct functional areas: sympathetic and parasympathetic. The autonomic nerve system and the categorization into sympathetic, parasympathetic, and enteric systems managing the intestinal tract were introduced by John Newport Langley (1852–1925), a physiologist from Great Britain. The autonomic nerve system is the part of the nerve system that controls visceral functions: breathing, digestion, HEART function and heart rate, perspiration, pupillary dilation, respiratory rate, salivation, swallowing, sexual arousal, and urination, to name a few, and supports consciousness. The sympathetic nerve system controls the response to stimuli (e.g., “flight or fight”) and maintains HOMEOSTASIS. The parasympathetic nerve system specifically manages the bodily maintenance such as defecation, digestion, salivation, sexual arousal, tear production (emotion), and urination (see Figure P.11).

Figure P.11 Illustration of the configuration for the parasympathetic nerve system.

Paraxial approximation

[acoustics, computational, optics] Ray-tracing SOLUTION in the regime of small ANGLE with respect to the main axis, generally the following holds: $\sin \xi \approx \xi$; $\tan \vartheta \approx \vartheta$; $\cos \xi \approx 1$. In OPTICS, this is the Gaussian approach or first-order approximation, tracing the beam as quasiparallel paraxial rays. In ACOUSTICS, the paraxial approximation considers the ultrasound TRANSDUCER beam, emitted as a SPHERICAL WAVE, and

approximates it as a quasiplanar wave assuming that the majority of sound is propagating in a fixed x -direction, and the AMPLITUDE profile can then be described by means of a diffraction correction term: $P = \partial v v_0 C(x, y, z, \omega) e^{i(kx - \omega t)}$, where v is the propagation velocity, $C(x, y, z, \omega)$ is the correction term, ANGULAR FREQUENCY $\omega_s = v_s 2\pi$, with v the acoustic frequency, P is the pressure, $\partial = \sqrt{(y^2 + z^2)}$ is the average critical dimension, and $k = 2\pi/\lambda$ is the wavenumber for wavelength λ (see Figure P.12).

Figure P.12 Paraxial rays in image formation.

Parent nucleus

[atomic, biomedical, general] In biology, this refers to a NUCLEUS in CELL division, which divides and produces two or more daughter nuclei. In atomic PHYSICS, this refers to RADIOACTIVE DECAY, where the parent nucleus (parent RADIONUCLIDE or parent RADIOISOTOPE) is the originating nucleus that decays with emission of ENERGY or particles, for instance, ^{238}U , the uranium parent for ALPHA DECAY with thulium as the “daughter.” More specifically, in nuclear decay the process refers to the components as nuclides (*also see* PARENT NUCLIDE).

Parent nuclide

[nuclear] In RADIOACTIVE DECAY, the parent nuclide can be long lived compared to daughter, or short lived. The parent can be naturally occurring or requires nuclear bombardment for formation. An ATOM is the smallest stable unit of an ELEMENT in existence. Each atom of the respective element consists of a certain number of electrons, protons, and neutrons, which define a nuclide and its chemical properties. These particles were discovered in the early 1900s and define modern atomic theory. Under the condition of decay, there are the following examples of naturally occurring long-lived parent nuclides: ^{86}Rb (rubidium), ^{100}Pd (palladium), ^{232}Th (thorium), ^{235}U (uranium), and ^{238}U (uranium); and artificially produced nuclides: ^{68}Ge (germanium; stable 270 days), ^{82}Sr (strontium; stable 25.6 days), and $^{188}_{74}\text{W}$ (tungsten; stable 69 days) all used in POSITRON EMISSION TOMOGRAPHY (PET). The NUCLIDE of certain atomic species are characterized by specific numbers of protons and neutrons (both called nucleons), representing the constitution of its NUCLEUS. The term nuclide was proposed in 1947 by Truman P. Kohman (1916–2010), referring to a species

of nucleus. Nuclides with the same atomic number (number of PROTON), but different NEUTRON numbers, are defined as isotopes of this element (*also see* PARENT NUCLEUS) (see Figure P.13).

Figure P.13 Parent nuclide concept: chart of nuclides. (Courtesy of American Nuclear Society.)

P

Parity

[atomic, computational, nuclear, quantum, solid-state] Property describing the characteristic state of a phenomenon, specifically the equality between conditions or the condition being odd or even, particularly referencing the quantum-mechanical state. The scientific implications of parity range from ELEMENTARY PARTICLES to the NUCLEUS and the wavefunction. For elementary particles, the “intrinsic parity” defines the conditions for conservation. The intrinsic parity conforms to an integer number +1 or −1, which is assigned to each individual elementary PARTICLE in such a way that the product of the parities of all the particles in a system, multiplied by the parity of the wavefunction, which describes the entire system, remains unchanged when particles are formed (created) or annihilated. For elementary particles (BARYONS, antibaryon, QUARK, antiquark), both strangeness (QUANTUM NUMBER: strangeness: S) and parity are conserved under strong (nuclear) interaction; however, weak interactions are exempt. Quarks have a defined intrinsic parity +1 and a defined antiquark parity −1. Nucleons, in general, have a defined intrinsic parity +1. In a complex system of a MESON with quark (“ q ”) and antiquark (“ $\bar{q}$ ”), assuming antiparallel spins ($s = 0$), yields for parity $P = P_q P_{\bar{q}} (-1)^\ell$, where ℓ is the orbital angular quantum number. The meson parity is defined as $P = -(-1)^\ell = (-1)^{\ell+1}$. For the nucleus, parity is associated with the TOTAL ANGULAR MOMENTUM quantum number (I), generally provided as superscript to the total angular momentum quantum number in denomination “+” or “−” (or “+1” associated with even orbital quantum number, and “−1” associated with odd orbital quantum number), as a multiplicative quantum number. Nuclear DECAY involving beta emission generally does not conserve parity. Nuclear states are identified as having both an intrinsic SPIN and a

well-defined parity, which is a function of the wavefunction for all the nucleons. The behavior of wavefunction of the nucleons under reversal of their coordinates, taking the origin at the center of the nucleus, will define the parity of the nuclear system. The parity of the WAVEFUNCTION (Ψ), which also applies to photons, is a property of symmetry as well, positive parity: $\Psi(x) = \Psi(-x)$, and negative parity: $\Psi(x) = -\Psi(-x)$. The wavefunction parity can be traced to the Hermite polynomials as a SOLUTION to the quantum-mechanical problem of the harmonic oscillator, using the PRINCIPAL QUANTUM NUMBER (n). Parity violation comes into play based on the fact that conservation of nuclear parity relies on the assumption that potentials involved in nuclear transitions are MIRROR symmetric. Nuclear conditions that are not symmetric and have loss of parity are considered to possess helicity, since a helix is not mirror symmetric (e.g., a human is not MIRROR symmetric on the MACROSCOPIC scale). Purely mathematically, parity is the fact whether an observation or a quantity is odd or even. Mesons have a specific parity, referred to as G-PARITY (see [Figure P.14](#)).

Figure P.14 Illustration of the concept of parity as a “condition” with opposite configuration.

Parity conservation rule

[atomic, nuclear, quantum, solid-state] In beta DECAY, the change in PARITY is $\Delta\pi_p = (-1)^{L_\beta}$ and the parity conservation rule accounts for this as $\pi_p = \pi_D (-1)^{L_\beta}$.

Partial pressure, Dalton's law of

[thermodynamics] See DALTON'S LAW.

Partial pressure of a constituent

[thermodynamics] The pressure of a GAS in a GAS MIXTURE (P_i) or as dissolved in LIQUID. In atmospheric AIR, there are several gasses with nitrogen the dominant component at 1 atmosphere ($1 \text{ atm} = 1.01325 \times 10^2 \text{ kPa}$) and normal temperature (293 K) holding $0.78 \text{ atm} = 7.90335 \times 10^1 \text{ kPa}$. For BLOOD, the partial pressure of oxygen is important for biological and physiological functions and efficacy of the metabolic reactions. One specific example is in the binding of oxygen to hemoglobin. The binding of oxygen to the protein LIGAND in hemoglobin can be described by the HILL EQUATION (*also see* DALTON'S LAW [of partial pressures]) (see Figure P.15).

Characteristic binding of O_2 with hemoglobin

Figure P.15 Graphical representation of the partial pressure concept.

Particle

[atomic, general, solid-state] Any MACROSCOPIC or MICROSCOPIC unit that is considered to be one piece. On a macroscopic scale, dust particles and RAIN drops are examples of a broad scale of presumably solid items, which specifically move as one object with respect to the external observer. The relative size of the object defines it as either a particle or an object; generally particles are less than a millimeter in diameter. On a microscopic scale, the particles range from molecules to atoms, electrons, protons, neutrons to elementary

particles of leptons, mesons and BARYONS, as well as respective antiparticles. Technically, a PHOTON is also considered a particle for a range of interactions (see [Figure P.16](#)).

Figure P.16 Concept of particles in air.

Particle accelerator

[atomic, general, nuclear] CYCLOTRON developed by ERNEST LAWRENCE (1901–1958) in 1934. Device for acceleration of charged particles such as protons, deuterons, and alpha particles under the influence of a MAGNETIC FIELD. The conduit used for the PARTICLE trajectory consists of a METAL tube that has two halves that are formed in the shade of opposite facing Ds, called “Dees,” where the path forms a continuous loop. Particles are injected under the influence of an external electric field, after which they experience a magnetic field inside the D-shaped tube. The maximum velocity ($v_{\max}$) obtained is a function of the radius of the cyclotron (R), the magnetic field strength (B), the respective particle charge (q), and the MASS (m) of the particle: $v_{\max} = q(BR/m)$, which will be ejected from the cyclotron, for instance to initiate a collision, with kinetic ENERGY: $(1/2)mv^2 = (1/2)q^2(B^2R^2/m)$, which can reach or exceed 30 MeV, above which relativistic effects start being introduced, for instance an increase of the period of the phenomenon as a function of radius. The classical MECHANICS period is $T = 2\pi m/qB$, for a particle moving in a circle with radius: $r = mv/qB$. Cyclotrons are nuclear colliders, for instance producing radioactive isotopes, next to FISSION and FUSION experimentation. The cyclotron in Batavia, IL, USA, has a diameter of 1.5 km, supporting research at the Fermi Laboratories. Other LINEAR ACCELERATORS (SYNCHROTRON) are also used for similar experimentation, for instance the Stanford, CA, USA accelerator is 3.3 km long and relies on an electric field along the length of the accelerator, harmonically fluctuating over the length of the evacuated tube, providing kinetic energies up to 50 GeV (see [Figure P.17](#)).

(b)

Figure P.17 (a) Areal view of a particle accelerator and (b) large hadron collider particle accelerator aerial view.

Particle accelerators, linear

[atomic, nuclear] *See* SYNCHROTRON.

Particle imaging velocimetry (PIV)

[fluid dynamics] Noninvasive optical laser imaging technique used in research and diagnostics of combustion processes, flow, MICROFLUIDICS, spray atomization as well as TURBULENCE. The PARTICLE concept relies on the use of “tracer” particles for tracking, combined with LIGHT delivery and imaging in a “single sheet” within the flow. The imaging process relies on a cross-correlation technique for “particle tracking.” Standard, MACROSCOPIC PIV uses imaging arrays and particularly “time-resolved” CMOS cameras in combination with laser scanning, while lab-on-a-chip devices are used in MICROSCOPIC imaging. PIV measures whole velocity fields by taking multiple consecutive images within approximately 6–10 ns time frame. The IMAGE processing calculates the DISTANCE and trajectory of individual particles within the image interval time. Based on the measured displacement over the time difference, the localized velocity can be calculated. Because of the anticipated fast flow, blurring needs to be avoided, which requires the use of fast laser pulses. Additionally, laser light can be focused into a thin light sheet, allowing only particles in a single plane to be imaged. The use of a high-speed CAMERA can rapidly store the first frame to subsequently acquire additional exposures (see [Figure P.18](#)).

Figure P.18 Particle imaging velocimetry design of experiment. Flow created in a transparent water channel is seeded with light-reflecting particles. The particulate solute are illuminated by a laser and the images of migration is captured by means of a high-resolution camera. The collected tracks of the particle flow derived from sequential images are processed to yield the volumetric instantaneous flow velocity measurements.

Particle in potential well

[nuclear] *See* SHELL MODEL.

Particle theory of light

[general, optics] Documented model of LIGHT by SIR ISAAC NEWTON (1642–1727) in 1704, describing light as small particles. The concept itself actually dates back to early Greek and Persian descriptions, specifically REFLECTION. In Newton’s description, refraction is also captured as the interaction of a PARTICLE at the surface of a medium, where it experiences a brief attractive force towards the medium, increasing the vertical component of the particle’s velocity. Since the particle is not exposed to any net horizontal forces, the resulting horizontal vector component of the velocity will remain constant. On the COLOR aspects, Newton also hypothesized that the mass of the light particle varied with color. RED light particles are heavier than violet. In refraction the red particle will experience a greater attractive force; hence the refraction ANGLE will be greater, thus explaining the workings of a PRISM. In order to account for POLARIZATION effect, Newton

postulated that light particles cannot be spherical. In order for polarization to be possible, the particles should either be plate-like or at least have “sides,” deviating from spherically symmetric (see [Figure P.19](#)).

Figure P.19 Illustration supporting the particle theory of light; a male “Great Tit” from the Paridae family of birds observing itself in the reflection from the water as we see both bird and image. The reflection can be described through the path of photons acting as tennis balls interacting with the reflective surface.

Particle tracking velocimetry (PTV)

[fluid dynamics] Technique to measure **PARTICLE** velocity, specifically applied to fluid-dynamic applications. This kind of **IMAGE** analysis algorithm is available in the tool kits of several commercial **SIGNAL** analysis software packages, often based on a Lagrangian reference frame (*also see* **PARTICLE IMAGING VELOCIMETRY**).

Partition coefficient

[biomedical, chemical] The ratio of the respective concentrations of a compound in an amalgam of two immiscible phases (e.g., two liquids, or a mobile with respect to a stationary **PHASE**, generally pertaining to the solubility of one **LIQUID** in another) while maintained at an **EQUILIBRIUM STATE**.

Partition function

[computational, mechanics, thermodynamics] Simple systems can be partitioned based on their respective quantum or energy states (E_i), which will follow the partition function: $Z_{\text{part}} = \sum_i e^{-\beta_T E_i}$, where $\beta_T = 1/k_b T$ is the “inverse temperature,” with $k_b = 1.3806488 \times 10^{-23} \text{ m}^2 \text{ kg/s}^2 \text{ K}$ the Boltzmann coefficient, and T the temperature in kelvin. For the harmonic oscillator, this becomes, based on the energy $E = [n + (1/2)]\hbar\omega$, $Z_{\text{part}} = e^{-(1/2)\beta_T \hbar\omega} / (1 - e^{-\beta_T \hbar\omega})$, where $\hbar = h/2\pi$, $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ is **PLANCK’S CONSTANT**, $\omega = 2\pi\nu$ the **ANGULAR VELOCITY**, ν the frequency, and n the **QUANTUM NUMBER**. On a mathematical basis, specifically in **PROBABILITY** theory, this also refers to a configuration integral, as a generalization, using the Hamiltonian (H) representing the potential function (which is measurable, is an observable): $Z_{\text{part}}(\beta_T) = \int \exp\{-\beta_T H(x_1, x_2, x_3, \dots)\} dx_1, dx_2, \dots$. Specific applications are in information science, **SIGNAL** processing, and pertaining to dynamical systems. In statistical **MECHANICS**, the free entropies of a system can frequently be expressed as the **LOGARITHM** of a partition function, specifically for the **ONSAGER RECIPROCAL RELATIONS**. In thermodynamic systems, the Onsager reciprocal relations are used to express the equality of particular ratios between forces and flows that are not specifically in equilibrium; however, local equilibrium may exist under strict boundary conditions.

Pascal (Pa)

[fluid dynamics, general] unit of pressure $1 \text{ Pa} = 1 \text{ N/m}^2$, named in honor of the groundbreaking work for standardizing pressure assessment by BLAISE PASCAL (1623–1662).

Pascal, Blaise (1623–1662)

[fluid dynamics, thermodynamics] Scientist, physicist, and mathematician from France. The work of Pascal is primarily known in FLUID DYNAMICS with respect to pressure, to which he lend his name as the unit for pressure. Other works of Pascal in the mathematical field are his contributions to the principle of probability as a contribution to the work of PIERRE DE FERMAT (1601–1665) (see [Figure P.20](#)).

Figure P.20 Blaise Pascal (1623–1662), engraved by H. Meyer.

Pascal, law of

[thermodynamics] See LAW OF PASCAL.

Pascal's law

[fluid dynamics] Mechanism of pressure operating in all directions. When in any point in a confined fluid there is an increase in pressure, there is an immediate and equal increase in pressure at every other point within the FLUID in the container that holds the fluid.

Pascal's principle

[fluid dynamics, general] The pressure applied to a FLUID is transferred equally and uniformly throughout the entire fluid. (described in the treatise of BLAISE PASCAL [1623–1662] “On the Equilibrium of Liquids,” approximately 1651). In his treatise, Pascal recognized that with force applied to a liquid, the DISTANCE traveled by the LIQUID and the applied force were linearly proportional irrespective of the surface area. In this manner, force can be scaled in a similar manner to a LEVER, using the hydraulic force applied over a larger area to be transferred proportionally to the ratio of the respective surface areas. The hydraulic LIFT provides the

most common example for this (fluid examples: water, oil). Hydraulic systems use incompressible fluids, whereas pneumatic systems use compressible fluids (e.g., AIR or gasses in general) (see [Figure P.21](#)).

Figure P.21 Hydraulic lift (automobile jack) working based on the Pascal principle, transferring force based on the surface area of the fluid column.

Paschen, Friedrich (1865–1947)

[atomic, nuclear, quantum] Physicist from Germany, dedicated to electro-optics. The PASCHEN LINES for hydrogen discharge (1908) are a key result of his work as well as other theoretical descriptions for electrical IONIZATION effects (see [Figure P.22](#)).

Figure P.22 Friedrich Paschen (1865–1947).

Paschen law

[atomic, nuclear] Also **Paschen's Law**. The breakdown voltage ($V_{\text{excitation}}$) for a GAS in a pressurized vessel exposed to electrical discharge will reduce in MAGNITUDE proportional to the gap (d) between the ANODE and CATHODE and the partial PRESSURE (p): $V_{\text{excitation}} = f(p, d)$, described by FRIEDRICH PASCHEN (1865–1947) in 1889. PASCHEN'S LAW reflects the atomic breakdown described by JOHN SEALY TOWNSEND (1868–1957). Townsend's work involved the analysis of the cascade effect of colliding electrons in an electrical discharge in gas between two electrodes, where the secondary electrons are gaining ENERGY under the influence of the applied electric field resulting in additional excitation effects induced by collision, providing enhanced IONIZATION (see [Figure P.23](#)).

Figure P.23 Paschen curves representative of the Paschen law.

Paschen lines

[atomic, general] See **PASCHEN SERIES**.

Paschen series

[atomic, general, nuclear] ATOMIC EMISSION wavelengths (λ), respectively, FREQUENCY (ν), as derived by FRIEDRICH PASCHEN (1865–1947), in particular for hydrogen, based on the BOHR ATOMIC MODEL transitions between electron orbits (n_i): $\nu = m_e c^4 Z^2 / 8 \epsilon_0^2 h^3 \left[(1/n_1^2) - (1/n_2^2) \right]$, for $n_1 = 3$, where $m_e = 9.10939 \times 10^{-31} \text{ kg}$ is the electron mass, $e = 1.60217657 \times 10^{-19} \text{ C}$ the charge equivalence of an electron [–] (or respectively, PROTON [+]), the permittivity of free space $\epsilon_{\text{EM0}} = 8.85419 \times 10^{-12} \text{ C}^2/\text{N m}^2$, PLANCK'S CONSTANT $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$, Z the number of charges in the NUCLEUS, and n_2 the respective originating electron orbits. Note that $n_1 = 1$ represents the LYMAN SERIES, $n_1 = 2$ is the BALMER SERIES, $n_1 = 4$ yields the Brackett series, and $n_1 = 5$ the Pfund lines, where $n_2 > n_1$ (see [Figure P.24](#)).

Figure P.24 Paschen line emission spectrum.

Paschen–Back effect

[atomic, general, nuclear, quantum] The coupling of the L -vector (total orbital momentum) and the S -vector (spin angular momentum) (i.e., RUSSELL–SAUNDERS COUPLING) regarding atomic transitions under the influence of very strong external MAGNETIC FIELD. In contrast, the absence an external magnetic field provides the “normal ZEEMAN EFFECT,” whereas a weak magnetic field induces the anomalous Zeeman effect. The Paschen–Back effect only affects changes in the L and m_L , completely neglecting the SPIN influences, as described by FRIEDRICH PASCHEN (1865–1947) and ERNST EMIL ALEXANDER BACK (1881–1959). The Paschen–Back effect resembles the normal Zeeman effect under restrictions of the “LANDE’S G-FACTOR” being 1: $\Delta E = \left(\frac{e\hbar}{2m_e} \right) m_j B$, where $e = 1.60217657 \times 10^{-19} \text{ C}$ is the electron charge equivalent, $\hbar = h/2\pi$, with PLANCK’S CONSTANT $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$, electron mass $m_e = 9.10939 \times 10^{-31} \text{ kg}$, m_j the QUANTUM NUMBER for the TOTAL ANGULAR MOMENTUM, and B the external magnetic field (*also see ZEEMAN EFFECT*).

Passenger car, drag coefficient

[fluid dynamics, mechanics] Automobile, two axles and four wheels propelled by gasoline, diesel, ELECTRICITY, natural GAS, or fuel cells. The DRAG COEFFICIENT of an automobile pertains to its AERODYNAMICS, and interrelated to its fuel economy (fuel consumption). Items that influence the aerodynamic properties are deviations from a perfectly smooth surface, such as a roof rack, curvature on the front and rear, as well as door-handle grips and windshield wipers, next to mudflaps behind the wheels and the encasing of the wheels, and also the definition of a front and rear “spoiler” makes an impact. The final design components that influence the drag are the length, height and width of the car, and the inherent frontal surface area (A), next to the velocity of both the independent airflow and the automobile PROPULSION, combined (v_{flow}); note that turbulent or LAMINAR FLOW will influence the final interaction, providing lower drag under turbulent flow. The drag coefficient (C_d) is derived from the resisting force ($F_d = C_d \left(\frac{\rho v_{\text{flow}}^2}{2} \right) A$) as $C_d = 2F_d / \rho v_{\text{flow}}^2 A$, where ρ represents the density of the FLUID in which the object is moving (i.e., AIR). The smaller the number the more aerodynamic the object. The power (e.g., horsepower) required to overcome the drag is $\dot{W} = F_d v_{\text{flow}}$. In addition to these factors, the REYNOLDS NUMBER also contributed to the final outcome of the influence of flow on the MOTION: $\text{Re} = v_{\text{flow}} L / \eta_{\text{visc}}$, where η_{visc} is the viscous RESISTANCE and L the characteristic length, meaning that the longer the automobile the more likely the flow along the body will be laminar. For $\text{Re} > 47$, BOUNDARY LAYER separation will take place, hence influencing the fluid resistance experienced by the body. Lowest COEFFICIENT OF DRAG on record for a production automobile at the

time of assembly of this record is the Mercedes CLA with $C_d = 0.23$, compared to that for a Ford Model T that resembles the drag of a cube at $C_d = 0.80$. Note that nonproduction automobiles may have superior values for drag coefficients in the front and side direction, but these are special cases, such as Formula One race cars (see Figure P.25).

(a)

(b)

Figure P.25 (a) Automobile drag coefficient and (b) Formula One race car with adjustable drag coefficient through adjustment of flaps and airfoils by means of remote control based on the on-the-fly measured road and air-flow conditions.

Passive resistance

[thermodynamics] States of equilibrium and the associated settings can respond to a change while meeting with a certain RESISTANCE, which has been termed passive resistance, based on the direction in which it acts. These equilibrium situations can generally be unstable. This instability will cause a potentially violent response and a respective change to an often very small disturbance. The disturbance in this case is small compared to the quantities within the system (*also* “inertia resistance”).

Passive state

[thermodynamics] Thermodynamic state that does not produce work (*also see* CANONICAL STATE).

Pauli, Wolfgang Ernst (1900–1958)

[atomic, computational, general, nuclear] Scientist and theoretical physicist from Austria. His work contributed to the understanding of the BOHR ATOMIC MODEL, and also to the formation and understanding of the WAVE MECHANICS principles in QUANTUM MECHANICS, associating wave theory with electron orbits (sometime referred to as “electron optics”), yielding stability conditions for electron orbits, limiting the number of electrons occupying a certain ENERGY level. The work of Pauli started out in 1925 in sync with the work of WERNER KARL HEISENBERG (1901–1976), ERWIN SCHRÖDINGER (1887–1961), and PAUL DIRAC (1902–1984). He is most known for his “EXCLUSION PRINCIPLE” pertaining to electron orbit occupation. Additionally, he introduced two new quantum numbers in 1924: the MAGNETIC QUANTUM NUMBER (m_ℓ) and the spin quantum number (m_s). He is one of the pioneers in quantum PHYSICS and received the Nobel Prize for his work in 1945 (see Figure P.26).

Figure P.26 (a) Wolfgang Ernst Pauli (1900–1958) at the 1933 Solvay Conference Structure et propriétés des noyaux atomiques: Structure and properties of the atomic nucleus; Chair Paul Langevin (1872–1946) (Courtesy of US Department of Energy (DOE) Washington, DC); (b) Wolfgang Pauli. (Courtesy of ETH-Bibliothek Zürich, Bildarchiv.)

Pauli exclusion principle

[atomic, nuclear] No two electrons in orbit in a single ATOM can exist in the same ENERGY and spin state. For instance, in helium the two electrons in the lowest energy state (with PRINCIPAL QUANTUM NUMBER $n = 1$) must have opposite SPIN states, with quantum numbers $\ell = 0$, $m_\ell = 0$ and $m_s = \pm(1/2)$. Electrons with the same principal quantum number will occupy the same “shell” (*also see* EXCLUSION PRINCIPLE).

Pauli spin matrix

[atomic, energy] Expression satisfying the commutator requirements describing the ELECTRON SPIN, represented as

$$\sigma_x = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \sigma_y = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}, \text{ and } \sigma_z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}.$$

The commutator requirement expressions are based on the angular momentum expressions: $L_x = \hbar / i [y(\partial/\partial z) - z(\partial/\partial y)]$, where $\hbar = h/2\pi$ with PLANCK'S CONSTANT $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$, and $L_y = \hbar / i [z(\partial/\partial x) - x(\partial/\partial z)]$, providing the commutators: $[L_x, L_y] = \hbar^2 [x(\partial/\partial y) - y(\partial/\partial x)] = i\hbar L_z$, $[L_y, L_z] = i\hbar L_x$, $[L_z, L_x] = i\hbar L_y$, and $[L_x, L_y] = i\hbar L_z$.

Paxillin

[biomedical, chemical, mechanics, signal] A 68 kDa neurofilament antibody cytoskeletal SIGNAL transduction adaptor protein involved in cellular organization as well as functioning of focal cellular adhesions. Paxillin adaptor proteins are critical in CELL ADHESION as well as in cellular migration.

PDT

[biomedical, chemical, optics] See PHOTODYNAMIC THERAPY.

Péclet, Jean Claude Eugène (1793–1857)

[energy, fluid dynamics] Physicist from France. He is most known for his contributions to FLUID dynamic definition and the PÉCLET NUMBER(S) (see Figure P.27).

Figure P.27 Jean Claude Eugène Péclet (1793–1857).

P

Péclet number (Pe)

[energy, fluid dynamics, thermodynamics] Dimensionless number used in HEAT TRANSFER representing the bulk heat transfer over the conductive heat transfer: $Pe = \nu L / \alpha = L \nu \rho c_p / \kappa = Re \times Pr$, with ν the velocity, L the characteristic length, α the thermal DIFFUSIVITY, κ the THERMAL CONDUCTIVITY, ρ density, c_p the heat capacity, Re the REYNOLDS NUMBER, and Pr the PRANDTL NUMBER. Generally used in forced convection and universal heat transfer. Named after the originator JEAN CLAUDE EUGÈNE PÉCLET (1793–1857).

Péclet number, mass transfer (Pe_m)

[energy, fluid dynamics, mechanics, thermodynamics] Dimensionless number used in mass transfer representing the bulk mass transport over DIFFUSIVITY of a constituent: $Pe_m = \nu L / D_{\text{dif}}$, with ν the velocity, L the characteristic length, α the thermal diffusivity, D_{dif} the DIFFUSION coefficient, based on the work of JEAN CLAUDE EUGÈNE PÉCLET (1793–1857). The mass transfer PÉCLET NUMBER is sometimes also referred to as the “SHEAR PÉCLET NUMBER,” specifically in SHEAR FLOW, such as in MICROFLUIDICS.

Peierls, Rudolf Ernst, Sir (1907–1995)

[acoustics, mechanics, solid-state] Scientist and physicist from Germany. His work on nuclear PHYSICS provided many theoretical insights, specifically treating the ATOM as having an electron cloud with discreet wavefunctions, different from the Schrödinger model (see [Figure P.28](#)).

Figure P.28 Rudolf Peierls (1907–1995), 1937 picture.

Peierls transition

[acoustics, mechanics, solid-state] Density WAVE in one-dimensional electron GAS. The ENERGY transfer takes place by exchanges between states, PARTICLE to particle transitions (Cooper channel), or particle to hole transitions (Peierls channel). The particle–hole transitions will exhibit periodic variations in charge density or SPIN density; as such these transitions are referred to as charge-density or spin-density wave GROUND states.

Peierls–Fröhlich–Kuper ground state

[acoustics, computational, mechanics, solid-state, thermodynamics] CHARGE DENSITY WAVE as a result of electron–phonon interaction in a partially filled electron band. Periodic lattice distortions create a single PARTICLE gap at the FERMI LEVEL. This transition forms an INSULATOR condition, known as the PEIERLS TRANSITION. The influence of an external electric field (nearby atoms or applied field creates a periodic instability as suggested by RUDOLF PEIERLS (1907–1995) in 1955, with theoretical support by Charles Goethe Kuper (twentieth century), and with independent contributions from HERBERT FRÖHLICH (1905–1991) in 1954 on a theoretical thermodynamic level. Under the particle gap migration, an electric current is generated on atomic level, specifically under the influence of an external electric field.

Peltier, Jean Charles Athanase (1785–1845)

[energy, thermodynamics] Physicist from France. He described the electrical potential resulting from placing two dissimilar materials in direct contact with each other—the PELTIER EFFECT (see [Figure P.29](#)).

Figure P.29 Jean Charles Athanase Peltier (1785–1845).

Peltier coefficient

[energy, thermodynamics] Representation of the heat quantity transferred per unit charge for a specific material, placed in contact with another material ($\cdot$): Π . This concept relates to the PELTIER EFFECT.

Peltier effect

[energy, thermodynamics] Electrochemical effect, describing the thermoelectric principles involved in the thermocouple ACTIVITY of two metals joined together. The two metals will absorb heat at the METAL junction that is at a higher temperature and emit heat at the lower temperature junction. This was described by JEAN CHARLES ATHANASE PELTIER (1785–1845) in 1834. Respectively, when an electrical source is connected in the THERMOCOUPLE circuit in the inverse direction, heat will be generated at the high-temperature junction and heat will be absorbed (cooling effect) at the colder junction. The Peltier effect is generally associated with electric heating and cooling. One specific example is the electric heating stove-top. The scientific description is defined as the rate of heat generated or removed as a function of ELECTRIC CURRENT (I): $\dot{Q} = (\Pi_A - \Pi_B)I$, where Π_A , respectively, Π_B , are the PELTIER COEFFICIENTS for the respective conductors joined together. A similar principle was described earlier in 1826 by THOMAS JOHANN SEEBECK (1770–1831), but is primarily credited to Peltier (see [Figure P.30](#)).

Figure P.30 Peltier element that cools based on the Peltier effect.

Pendulum

[general] Physical body that will rotate around a fixed axis when an external force is applied to initiate the removal from EQUILIBRIUM STATE; the device will produce a simple periodic MOTION. The first pendulum-based clock was constructed in 1657 by the scientist from the Netherlands: CHRISTIAN HUYGENS (1629–1695), who also developed the mathematical formulation for the pendulum. The pendulum will have a harmonic period (T) that is a function of the length from the axis of rotation to the center of mass (ℓ), the mass at the center of mass (m), the GRAVITATIONAL ACCELERATION (g), as well as the generalized MOMENT OF INERTIA (I_{inertia}), expressed as $T_{\text{period}} = 2\pi\sqrt{I_{\text{inertia}}/mg\ell}$. The pendulum, for small angular displacement ($\sin \theta \approx \theta$, where $\theta = A \sin(\omega t + \phi)$, with ϕ an arbitrary initial PHASE of motion (depending on the time of initiation of observation) and ω the ANGULAR VELOCITY, $\omega = \sqrt{g/\ell} = \sqrt{(mg\ell/I_{\text{inertia}})}$ as a function of time (t), without friction obeys the WAVE EQUATION ($\partial^2\theta/\partial t^2 + (g/\ell)\sin \theta = 0$). When considering that the pendulum experiences friction at the movement around the axis, the wave equation incorporates dampening as $I_{\text{inertia}}(\partial^2\theta/\partial t^2) + mg\ell\theta = \pm \tau_{\text{friction}}$, where τ_{friction} represents the torque resulting from the rotational friction with respect to the center of mass. The SOLUTION then yields a dampened angular swing, with decreasing displacement: $\theta(t) = [\theta_0 - (4t\tau_{\text{friction}}/\omega_0^2 I_{\text{inertia}} T_{\text{period}})]$. When the pendulum is submerged in a viscous fluid, the wave equation incorporates dampening as $I_{\text{inertia}}(\partial^2\theta/\partial t^2) + b_{\text{visc}}(\partial\theta/\partial t) + mg\ell\theta = 0$, where b_{visc} represents the viscous friction with respect to the center of mass, with ensuing DAMPING term $b(\partial\theta/\partial t)$. The fluid-dampened OSCILLATION has the solution $\theta(t) = \theta_0 e^{-b_{\text{visc}}t/2I_{\text{inertia}}} \cos(\omega' t + \phi)$, where the oscillation period decreases, expressed as $\omega' = \sqrt{((mg\ell/I_{\text{inertia}}) - \{b_{\text{visc}}/2I_{\text{inertia}}\}^2)}$, and $\gamma_{\text{damp}} = b_{\text{visc}}/2I_{\text{inertia}}$ is the dampening constant. GALILEO GALILEI (1564–1642) also worked on the pendulum concept, dating back to 1582, but never constructed a clock mechanism, nor defined the rhythmic motion aspects. Generally, a pendulum

is driven by a weight mechanism to maintain motion. The FRICTION from liquids will result in a dampened motion, except for in VACUUM; however, the gear and sliding friction also reduce the ENERGY content (see [Figure P.31](#)).

Figure P.31 Pendulum of a clock, ensuring proper time keeping. Sometimes adjustments to the length of the pendulum of a clock are required for calibration purposes.

Penumbra

[biomedical, general, geophysics] PHASE in “shadow” pattern created by an OPAQUE object irradiated from behind. The source can be a PARTICLE source or emit ELECTROMAGNETIC RADIATION. The three phases recognized are umbra, penumbra, and antumbra. During a penumbra only a portion (edge) of an emission source is obscured by the object, casting a shadow resembling a finger-nail clipping, as seen during the onset of a total eclipse of the SUN or generally a partial eclipse. The umbra represents a total blackout of the source on a projected surface, or when observed straight on (*Note:* Not advisable during the observation of a solar eclipse, since when the Sun peaks back out the radiance can literally be blinding.) and the antumbra has LIGHT passing around the object. Note that for a POINT SOURCE, only the umbra is produced. In biomedical

applications, this applies to RADIATION THERAPY, where the penumbra represents the biological space in the periphery of the spot irradiation location, and is generally defined as the tissue volume receiving only a partial dose, between 80% and 20% of the therapeutically intended isodose (see [Figure P.32](#)).

Figure P.32 Lunar eclipse, penumbra.

Perception

[biomedical, chemical, mechanics, optical, theoretical] Parameter of sensation. A sensation is quantified and qualified by several attributes and parameters, also defined as dimensions. One “quality” of a sensation is the subjective value that provides a name. The clinical classification of the senses is as follows. Special senses are VISION, auditory, taste, olfactory (smell), and vestibular (balance, equilibrium, spatial orientation; located in the vestibular system of the INNER EAR). Other superficial or cutaneous senses are touch/pressure, warmth, cold (separate from warmth), and pain (most overstimuli can produce pain in any of the sensing neurons with sensor specialization). Deep sensations are muscle/tendon/joint and position, deep pressure, and deep pain. Visceral sensations served by the autonomic nervous system are hunger and nausea for instance and visceral pain. Senses can also be organized by “location.” Somatic (“body”) senses are for instance temperature, either warm or cold; touch pressure; pain, next to “deep sensibility.” Deep sensibility is an indication of the knowledge and awareness to the relative position of the extremities (arms/legs; i.e., “muscle sense”) and the perception of the direction of MOTION with eyes closed. Generally, a power function can be attached to the sensation that links the MAGNITUDE of the stimulus (S) to the psychological magnitude (M): $M = K_{\text{sens}} S^2$, where K_{sens} represents a “personal” factor (“sensitivity,” “numbness”). Sensors can also be classified by their function: chemoreceptor, mechanoreceptor, and optical sensor. The sensation is ultimately a function of the type of nerve-fiber/sensor combination that is stimulated, not the ENERGY of the stimulus itself. The magnitude of the stimulus of the sense is encoded in a binary frequency train, which is logarithmically linked to the strength of the excitation. The fine free nerve-ending in hairy SKIN as well as nerve-baskets around the

hair roots are serving a variety of sensations, ranging from touch, to warm and cold. Specialized sensors are constructed of encapsulated nerve-endings, with various configurations and designs for specific applications; RODS and CONES for the RETINA of the EYE for instance. The RESOLUTION of a sense is a function of the number of sensors per unit area (sensor density); the fingertips of a mammal can gauge submillimeter resolution, whereas the palm spans several millimeters. Another highly innervated area is the lips. Since the lips are close to the brain, and conversely fast conducting nerves (i.e., myelinated nerves) are formed only slowly after birth, the lips are the most direct link to the brain for babies, most likely the reason why they touch everything with their mouth since the fingertips are not fully developed. Generally, several neurons carry information from different locations to the same functional area in the brain. Under normal conditions the brain can identify exactly where the sensation originates (potentially imbedded in other types of encoding, possibly “PHASE ENCODING,” which for a binary system is different than for an analog system, for instance using a phase shift for a “marker” pulse segment), whereas under overstimulus (very strong stimulus) the sensation is “projected” to the most distal point on the perception branch (see [Figure P.33](#)).

Figure P.33 Cartoon representation for sensory perception. Hearing, smell, taste, and sight; not specifically included: touch; however the lips have the highest density of sensors, providing resolution of better than 0.05 mm.

Perceptron

[biomedical, computational] Computational algorithm used in machine learning. The algorithm is designed to detect a linear threshold for an event or data trend. The linear function in vector components can be represented as $a_1x_1 + a_2x_2 + \dots + a_ix_i + \dots + a_nx_n > 0$ and in vector format as $\vec{a}^1 \cdot \vec{x} > 0$, threshold at zero, where $\vec{a}^1$ is a unit length vector. In a sequence (S_{seq}) of data with potential mistakes (M_{mis}), the “margin” (γ_{marg}) in the mistakes for the perceptron algorithm is $\gamma_{\text{marg}} = \min_{x \in S_{\text{seq}}} |\vec{a}^1 \cdot \vec{x}| / \|\vec{x}\|$, with the number of mistakes in the order of $(1/\gamma_{\text{marg}})^2$. This is one of the early concepts in machine learning, introduced in the early 1960s.

Percolation

[chemical, computational, geophysics] In chemical applications percolation references the filtration system, while in computational theory this defines the interrelation of data clusters in a graph that are connected (“neighbors”). Additionally, in geology, percolation refers to the CIRCULATION of water and the inherent filtration of water through the soil of the mantle as well as permeable rocks. The percolated water seeps to groundwater storage (i.e., aquifer). One particular mathematical use of percolation refers to the probabilistic interactions during PHASE transitions. The phase transitions are outlined in graphical representation (e.g., PV-DIAGRAM) for a region in the medium; percolation can describe the PROBABILITY (p) that the “edges” of the segment are open to the neighboring vertices (faces and edges; intersection in geometric space). Image and SIGNAL percolation generally involves finite ELEMENT analysis (Monte Carlo simulation) (see [Figure P.34](#)).

Figure P.34 (a) Image analysis percolation and (b) percolation of water in the atmospheric circulation and drainage to aquifer to be stored underground, ultimately with the opportunity to be used as drinking water due to the cleaning from the seepage.

Perfect diamagnetism

[general] Generally DIAMAGNETISM is the result of atomic current loop in response to an applied external MAGNETIC FIELD. The induced currents result in a magnetization within the diamagnetic material with a direction that opposes the applied field. When the external field is removed the magnetization disappears. The relationship between magnetization (M_{mag}) and the magnetic field (B) is expressed as a function of the volume MAGNETIC SUSCEPTIBILITY (χ_m) as $M_{\text{mag}} = \chi_m B$. In superconductor material, the magnetic field is zero and hence there will be no magnetization, that is, perfect diamagnetism (*also see* MEISSNER EFFECT *and* DIAMAGNETISM).

Perfect gas

[fluid dynamics, thermodynamics] An IDEAL GAS that has simplified stable equilibrium conditions (specifically behaving with a weak, dependence of the SPECIFIC HEAT on the temperature (in most cases negligible; i.e., $c_p = \text{constant}$ [constant pressure: P] and $c_v = \text{constant}$ [constant volume: V]), yielding $c_p - c_v = R$, where $R = 8.3144621(75) \text{ J/K mol}$ is the gas constant, and $c_p/c_v = \gamma_p$ a constant within a specific temperature range. The specific INTERNAL ENERGY of a perfect gas is defined as $U(T) - U_0 = (1/\gamma_p - 1)(PV - P_0V_0) = c_v(T - T_0)$, Δ_0 ; $V_0 = R(T_0/P_0)$ denoting the GROUND STATE or initial state. The specific enthalpy is defined by $h(T) - h_0 = [\gamma_p/(\gamma_p - 1)](PV - P_0V_0) = c_p(T - T_0)$. And finally the specific entropy as a function of combinations of respectively temperature, pressure, and volume: $S(T, P) - S_0 = c_p \ln(T/T_0) - R \ln(P/P_0)$, S_0 at P_0, T_0, V_0 (similarly for h_0 and U_0); $S(T, V) - S_0 = c_v \ln(V/V_0) + R \ln(P/P_0)$; $S(V, P) - S_0 = c_p \ln(V/V_0) - c_v \ln(P/P_0)$. Additionally, for the perfect gas along any ISENTROPIC the following holds: $TP^{-\gamma_p-1/\gamma_p} = \text{Constant}$; $TV^{\gamma_p-1} = \text{Konstant}$; and $PV^{\gamma_p} = \text{Konstant}$ (*also see* IDEAL GAS); however, the ideal gas is not necessarily equal to the perfect gas.

Perfect incompressible behavior

[fluid dynamics, geophysics, mechanics, thermodynamics] Poisson's ratio for incompressible media is $\nu_p = 0.5$. Incompressible VISCOELASTIC behavior has as boundary condition that the strain is finite. The MAGNITUDE of allowable finite strain is a function of the medium. Theoretically, media can have perfect incompressible behavior for several phases (solid, LIQUID, or gas). The equation of MOTION for perfect INCOMPRESSIBLE FLUID behavior assuming the absence of internal FRICTION was described by LEONARD EULER (1707–1783). Examples of materials that approach perfect incompressible behavior are several polymers: polystyrene, polycarbonate, polyvinyl acetate; as well as vulcanized natural rubber. Generally, the bulk modulus will decrease for a medium approaching $\nu_p \rightarrow 0.5$, and mathematically the ratio of bulk modulus to shear modulus will trend to infinity. Incompressible flow is described by the Euler equations.

Perfusion

[biomedical, fluid dynamics] Integral network of BLOOD vessels supplying nutrients and oxygen to bulk tissues and organs and removing waste and carbon dioxide. Vessels consisting of arteries, arterioles, capillaries, venules, and veins (see [Figure P.35](#)).

Figure P.35 Blood perfusion of lung tissue around the alveoli exchanging oxygen and carbon dioxide.

Pergrinus, Petri, a.k.a. Pierre de Maricourt (1220–1290)

[electromagnetism] Scientist from France, accredited with the first documented description of the use of the Earth's magnetism using a needle to map the MAGNETIC fields produced by magnetic objects as well as the Earth's MAGNETIC FIELD line patterns. Magnetic fields introduced by objects/particles and the Earth's magnetic field were known as far back as the thirteenth century before Christ. The work by Pergrinus postdates the early recording by almost 24 centuries (see [Figure P.36](#)).

Figure P.36 Plaque commemorating Petrus Peregrinus de Maricourt; a.k.a. Petri Pergrinus (1220–1290), a.k.a. Pierre de Maricourt.

Period doubling

[biomedical, computational] Sudden doubling of the frequency of a (PENDULUM) event. This may be graphically illustrated as a bifurcation in a POINCARÉ SECTION of an orbital plot in a QUALITY FACTOR versus ν -coordinate ($\nu = d\theta/dt$, where θ represents the angular path of a pendulum). In the statistical analysis of animal population as a function of time, on average the population will persistently gyrate between two values as a function of time with no consistent equilibrium. The rate of growth is a function of the fertility, which is a function of environmental and seasonal factors. Considering the dependence of an animal population as a function of its rate of growth will display a “bifurcation” for the population value as a function of growth. At a certain value of the rate, there is no established equilibrium in the population, and the number alternates between two values. This process of “bifurcation” continues, and the population will subsequently dissolve into chaos (see Figure P.37).

Figure P.37 Period doubling in population growth estimation based on graphical representation.

Period of a cycle (T)

[acoustics, general, mechanics, optics] The time frame (t) required to bring a period event back to a well-defined prior state (MAGNITUDE of displacement, field strength) with the same change of state configuration, primarily associated with a sinusoidal phenomenon such as a WAVE: $\mathcal{A} = \mathcal{A}_0 \sin[(t/T)2\pi]$ (see Figure P.38)

Figure P.38 Period, time to complete one sequence of events to the point where everything repeats itself, as in the revolution of a Ferris wheel, once around within a certain timespan.

Periodic law

[solid-state] Description of the perceived regular pattern in ATOM structural configuration with respect to electron structure as the basis for the PERIODIC TABLE OF ELEMENTS, introduced by DMITRI MENDELEEV (1834–1907).

Periodic table of elements

[atomic, nuclear] Discrete pattern of atomic configurations, nuclides, and electron orbits for the ELEMENTS as introduced by DMITRI MENDELEEV (1834–1907). The table designed by Dmitri Mendeleev listed the elements according to ATOMIC WEIGHT. In 1913 amateur theoretical physicist and economist Anton van den Broek (1870–1926) from the Netherlands suggested that the ordering principle for the periodic table should be based on ordinal numbers, i.e., the NUCLEAR CHARGE of each ATOM. This principle was validated by HENRY GWYN JEFFREYS MOSELEY (1887–1915) from Great Britain shortly thereafter, providing the final structure for the current use of the periodic table (see [Figure P.39](#)).

P

P

P

Periodic waves

[general] Harmonic principle of ENERGY flow, where the MAGNITUDE of the representative phenomenon (e.g., mechanical deflection, electric or MAGNETIC FIELD strength, etc.) fluctuates with a fixed rhythm, indicated by the period of the WAVE (T), or the FREQUENCY ($\nu = 1/T$, expressed in Hertz [Hz]).

Periodogram

[acoustics, astronomy, computational, mechanics, optics] Periodogram is the statistical analysis of a time series of events that are not always periodic in nature. The events can be objects placed in a two-dimensional space (e.g. telephone poles) or sound AMPLITUDES, respectively light (ELECTROMAGNETIC RADIATION). One item of particular interest to the analysis by means of periodograms is in the occurrence of sunspots. Generally, a FOURIER TRANSFORM may not capture all the frequency data due to the unique and unevenly distributed nature of the events. The concept of the periodogram was introduced in the late 1800s. The periodogram concept can be in principle attributed to Sir Franz Arthur Friedrich Schuster (1851–1934), published in 1897. The periodogram analysis uses the discrete Fourier transform (DFT) as a basis, but requires several stages of averaging: *smoothing*. The periodogram uses the squared modulus of the DFT at selected frequencies, applied in asymptotic approximation. The FREQUENCY SPECTRUM analysis for the periodogram is primarily a statistical estimation process. It is the MAGNITUDE and span approximation for the spectral density of a periodic or discrete SIGNAL. A mathematical and statistical concept used to break down a complicated object of data stream, for instance a time series, into a sum of objects (e.g., spectral or temporal components) with reduced simplicity: $x(t) - \bar{x} = \sum_{k=2}^{(n/2)+1} \gamma_k \{a_k \cos[2\pi(t-1)\omega_k] + b_k \sin[2\pi(t-1)\omega_k]\}$, where ω_k represents the frequency components, $\gamma_k = 2$ unless $k = 1$, and a_k, b_k respectively the real and imaginary components of the Fourier transform of the data series. The individual components can then be studied separately. The less important components (low probability of impacting the overall outcome) can potentially be discarded to form a general approximation of the original phenomenon or object (also see FAST FOURIER TRANSFORM [FFT]) (see Figure P.40).

Figure P.40 Periodogram for the sound from voice over a time frame of 15 seconds, showing an amplitude graph for a section of 2.8 seconds only, with the calculated voice frequency on the right spectrum. Calculations performed by Matlab-MathWorks, Natick, MA, US. <http://www.mathworks.com/help/signal/ref/periodogram.html?requestedDomain=www.mathworks.com>. (Courtesy of National Center for Supercomputing Applications (NCSA) at the University of Illinois, Urbana, IL; Fortner Software, Unidata Program Center (netCDF), Boulder, CO; , The Independent JPEG Group (JPEG), Jean-loup Gailly and Mark Adler (gzip), and Digital Equipment Corporation (DEC), Maynard, MA.

Periphractic region

[fluid dynamics] Region in an irrotational segment of a moving FLUID, or electric respectively magnetic FLUX, which is defined by one or more closed surfaces. Also see **APERIPHRACTIC**, as found pertaining to Maxwell theory, where a closed surface may be contracted down to a point without losing the confinement for the region.

Peristaltic motion

[biomedical, mechanics] Sequential relaxation and subsequent contraction of circular muscles in antero-grade MOTION to form a WAVE-like propagation that mechanically transports the content within a biological tube, as found in the gastrointestinal track. The MUSCLE structure is smooth muscle. Certain worms also use this mechanism for in-line advancement on the exterior (see [Figure P.41](#)).

Figure P.41 The peristaltic motion of the esophagus as a result of swallowing food.

Perkins, Donald Hill (1925–)

[high-energy, nuclear] Physicist from Great Britain. He is best known for his contributions in PARTICLE physics, specifically the discovery of the negative PION in cosmic RADIATION (see [Figure P.42](#)).

Figure P.42 Donald Hill Perkins (1925–). (Courtesy of Physics Institute of the University of Bonn, Bonn, Germany.)

Permanent magnet

[general] See MAGNET.

Permeability (μ_{mag})

[biomedical, electromagnetism, energy, general, thermodynamics] $\mu_0^{\text{mag}} = 4\pi \times 10^{-7} \text{ H m}^{-1}$ for free space. Material property describing the ratio of the MAGNITUDE of magnetization (i.e., magnetic intensity) under the influence of a current through the material in a annular shape to the intensity of magnetization produced by the same current through a nonferromagnetic material with the same configuration of windings and dimensions. The permeability is an indication of the ability of the material to sustain the MAGNETIC FIELD. Generally, the permeability is a function of the magnetization itself, specifically for ferromagnetic media.

Permittivity (ϵ_{elec})

[biomedical, energy, general, thermodynamics] The electric field response of a medium under the influence of an applied external electric field. Measure of electric RESISTANCE of a medium under the process of forming an electric field within the medium. Note that the electric field is the electric potential per unit length resulting from separation of charges; how easily are the charges in a medium polarized under the influence of an external electric field. In a related definition, the electric susceptibility is an indication of the degree of POLARIZATION for a medium under the influence of an external electric field, the ease at which charges can be reorganized. The permittivity is the product of the RELATIVE PERMITTIVITY (ϵ_r) and the permittivity of free space ($\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2 / \text{N m}^2$).

Pérot, Jean-Baptiste Alfred (1863–1925)

[electronics, optics] Also PEROT French physicist most known for his work on interferometry with CHARLES FABRY (1867–1945). In spectroscopic analysis, the team developed the FABRY–PÉROT INTERFEROMETER (see [Figure P.43](#)).

Figure P.43 Jean-Baptiste Alfred Pérot (1863–1925).

Perpetual motion

[general] Any finite system by definition has finite INTERNAL ENERGY. In case a machine, or a system in general, performs work, energy is exchanged with the external system and the mechanism will have a decrease in internal energy by definition of CONSERVATION OF ENERGY (FIRST LAW OF THERMODYNAMICS). In case of perpetual motion, the system is supposedly crating more energy than it is producing allowing it to operate indefinitely without fuel (i.e., externally added energy). The system that operates for infinite period of time without contribution of external energy is referred to as the hypothetical case of perpetual motion of the first kind, which is theoretically and practically impossible. Perpetual motion of the second kind is claiming the possibility of extracting energy from the outside system without the requirements of a thermal gradient towards the system. This phenomenon would not violate the FIRST LAW OF THERMODYNAMICS; however, since it would supposedly effortlessly extract energy from the environment, this will violate the SECOND LAW OF THERMODYNAMICS, which prescribes a thermal gradient in order for heat to FLOW. The perpetual motion of the second kind presumably could extract energy against the gradient, that is, from a colder system, which is a practical and theoretical impossibility. The perpetual motion of the second kind however does not claim an infinite lifetime of operation, nor does it generate more energy than it consumes, but is still highly improbable and unrealistic (see [Figure P.44](#)).

Figure P.44 (a) Apparent perpetual motion, the fact that a significant amount of energy was required to produce the “bouncing ball” device (i.e., Newton Cradle) and the fact that one ball needs to be pulled away initially by means of an external force by definition disqualify this device as a perpetual motion machine and (b) atomic motion is the closest system satisfying the perpetual motion theorem; still energy was added to this system during the primordial creation mechanism.

Perrin, Jean Baptiste (1870–1942)

[atomic, general, nuclear] Physicist from France who described the PHOTOELECTRIC EFFECT. Additional work by Perrin involved the BROWNIAN MOTION. He employed the description of Brownian motion provided by Einstein to derive the value of the Avogadro number. His work provided the following values for Avogadro's number $68.2 \times 10^{22} \text{ mol}^{-1}$ under the investigation of vertical velocity distribution; $68.8 \times 10^{22} \text{ mol}^{-1}$ for translational displacement; $65 \times 10^{22} \text{ mol}^{-1}$ under rotational DIFFUSION; and $69 \times 10^{22} \text{ mol}^{-1}$ under diffusion MEASUREMENT in the early 1900s, with respect to the established value (est. 2011; based on the work of LORENZO ROMANO AMEDEO CARLO AVOGADRO [1776–1856] in 1811) $N_a = 6.02213678 \times 10^{23} \text{ mol}^{-1}$. His work on CATHODE RAYS proved that their nature consisted of negatively charged particles. He also studied the effect on conductivity of gasses under the influence of X-RAY RADIATION. In addition, his work encompassed FLUORESCENCE, the disintegration of the radium isotope, next to the general phenomenon of emission and transmission of ACOUSTIC ENERGY (i.e., SOUND) (see Figure P.45).

Figure P.45 Jean Baptiste Perrin (1870–1942).

Persistence time

[biomedical, computational, energy, general, mechanics] The average time frame between MOTION occurrences of significant influence relating CELL MOTILITY, for example, change in direction or MAGNITUDE: $\tau_{\text{persistence}} = \left\{ \theta_T (1 - \sin \phi) \right\}^{-1}$, where θ_T is the average time interval between two changes in direction and ϕ is the ANGLE between the prior direction and the new direction.

Perturbation theory

[atomic, computational] In wave MECHANICS the eigenfunctions of an applicable operator, such as the Hamiltonian ($H\Psi$), can be expanded in series. For certain cases, in atomic PHYSICS an exact NUMERICAL solution to the SCHRÖDINGER EQUATION may not be attainable. The case of perturbations in the Hamiltonian pertaining to fluctuations in the local potential can be difficult to ascertain. On a MACROSCOPIC scale, the same principles have been applied to the definition of PLANETARY ORBITS, first assumed to be circular, later found to be *approximating* elliptical tracks, due to various external influences. The process for the PLANETARY MOTION uses the following perturbation mechanism: first assume a single PLANET in an elliptical orbit, next add additional planets, and implement their influences (assuming that they also only move in an elliptical orbit; first perturbation). This allows the approximation of the velocity and the displacement of the planet. In the second-order approximation, the other planets will be calculated for their deviations on a recursive method, and the respective influence on the primary planet of interest. In the quantum-mechanical approach, generally the perturbations will proceed past the first order for initial investigations. The Hamiltonian can be enriched by a perturbing term (H' , perturbing Hamiltonian between quantum states): $H^* = H_0 + H'$, which is subsequently used in the Schrödinger equation: $H^* \Psi_k = E_k \Psi_k$, where E_k is the primary ENERGY distribution, and the solutions have the associated orthonormal eigenvalues (u_i). In first order, this yields only the direct influences, canceling out interactions between states $m \neq n$, at the perturbation $\square_m$: $\sum_{n=1}^{\infty} a_{kn} H'_{mn} = (E_k - E_{0m}) a_{km}$, where $H'_{mn} = \int u_m^* H' u_n d\tau$ is the matrix ELEMENT of the perturbing Hamiltonian H' between states m and k , with u_m^* the complex conjugate EIGENVALUE, $E_k = \sum_{n=1}^{\infty} a_{kn} u_n$, a_{kn} the EXPANSION coefficient (which are all zero except for a_{kk}), and $a_{km} \cong H'_{mk} / (E_{0k} - E_{0m})$ under the approximation $E_k \approx E_{0k}$. The simple example is for a square POTENTIAL WELL. A time-dependent version will apply to photon emission, gamma DECAY, beta and alpha emission as well as atomic and NUCLIDE collisions; this process involves a change of state, for instance from excited to GROUND STATE under photon emission. In this case, the state is defined as $\Psi = \psi_m e^{-(E_m/\hbar)t}$, with PLANCK'S CONSTANT $\hbar = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$, which in this case will be required to satisfy the Schrödinger time-dependent equation: $H^* \Psi = i\hbar (\partial \Psi / \partial t)$, where $\hbar = h/2\pi$, and t denotes time. This provides a SOLUTION that yields the transition rate (λ_{trans}) from state ψ_m to all other states as $\lambda_{\text{trans}} = 2\pi/\hbar |H'_{km}|^2 (dN/dE)$, with N representing the accessible final states, and dN/dE the accessible final states per unit energy. The exact final state itself after transition can in general not be determined or experimentally derived. This last part is often referenced as “golden rule number two” (in the first-order perturbation approximation). The first-order probability of finding the system in state ψ_k is found to be $P_{\psi_k} = \left\{ (1/i\hbar) \int_0^t H'_{km} e^{-i\omega_{km}t} dt \right\}^2$, where $\omega_{km} \equiv (E_k - E_m)/\hbar$. (Note: “golden rule number one” applies to second-order perturbations, specifically where the matrix ELEMENTS H'_{km} will vanish under exchanges that do not violate the CONSERVATION LAWS.)

PET tracer

[biomedical, imaging] Radioisotopes that are used to TRACE specific metabolic or biological events in combination with POSITRON EMISSION TOMOGRAPHY (PET) imaging. For instance, ^{18}F —fluorodeoxyglucose has a half-life of 110 min, becomes part of the GLUCOSE, and is used to track tissue ACTIVITY (used in cancer research, neurology, and cardiology), ^{18}F —fluoride has a half-life of 110 min and is used in bone imaging, ^{11}C —PK11195 has a half-life of 20 min and is used for determining microglial activation, specifically associated with various neuroinflammatory and neurodegenerative diseases. Many more TRACERS are available to monitor physiological and anatomical features ranging from BLOOD flow, hypoxia, CELL binding studies, to dopamine receptor binding characteristics (e.g., drug efficacy), and cerebral ischemia as well as behavior studies based in viral infections (linking to the virus).

Peters, Bernard (1910–1993)

[atomic, geophysics, nuclear] Scientist from Poland (Prussia), contributor to the determination of the primary cosmic ray FLUX of nuclei with atomic number $Z \geq 2$, some in collaboration with Helmut L. Bradt (–1950). Peters and Bradt collected a significant amount of data during a balloon flight in 1948. This work provided essential information with regard to the ionizing potential with respect to the Earth's ATMOSPHERE (see [Figure P.46](#)).

Figure P.46 (a) Bernard Peters (1910–1993) in 1959 (Courtesy of Niels Bohr Archive, Copenhagen, Denmark.) and (b) outline of atmospheric ionization based on the work of Bernard Peters.

Petit, Alexis Thérèse (1791–1820)

[thermodynamics] Physicist from France. His work provided significant insight into the efficiency of steam engines. Additional work was his discovery of the combustible nitrogen trichloride in 1813. Several efforts in his thermodynamic field were with PIERRE LOUIS DULONG (1785–1838) (see **LAW OF DULONG AND PETIT**) (see [Figure P.47](#)).

Figure P.47 Alexis Thérèse Petit (1791–1820).

Pfaff, Johann Friedrich (1765–1825)

[computational] Mathematician from Germany. His main focus was on special differential equations; specifically, he developed a method to solve series of complex interrelated functions, known as PFAFFIAN equations, which generally cannot be solved through normal mathematical mechanisms. One person particularly interest in Pfaff's work was JOHANN CARL FRIEDRICH GAUSS (GAUß) (1777–1855), pertaining to solving complex geometries for the derivation of the specific shape of MAGNETIC FIELD lines (see [Figure P.48](#)).

Figure P.48 Johann Friedrich Pfaff (1765–1825).

Pfaffian

[computational, thermodynamics] Differential equation with specific geometric configuration: $df = \sum_{i=1}^n X_i dx_i$, where the functions/phenomena X_i are dependent on individual or all the independent variables x_i . This equation is generally not considered to be a normal differential equation. The Pfaffian equation is for the specific condition: $df = \sum_{i=1}^n X_i dx_i = 0$. This process was developed by JOHAN PFAFF (1765–1825). These types of special differential equations often come into play in the field of axiomatic THERMODYNAMICS, based on the work of the German mathematician CONSTANTIN CARATHÉODORY (1873–1950) published in 1909, on an axiomatic approach to thermodynamics.

Pfund, August Herman (1879–1949)

[atomic, nuclear] Physicist and spectroscopist from the United States. Additional work by Pfund involved the invention and creation of a specialized spectroscopic TELESCOPE: the Pfund telescope. The mechanism of action of the Pfund telescope applies a method for realizing a fixed FOCAL POINT regardless of the

positioning of the line of sight of the telescope. Other work by Pfund was the creation of a special compass in 1944 in the investigation of POLARIZATION by the sky, called the Pfund sky compass (see [Figure P.49](#)).

Figure P.49 August Herman Pfund (1879–1949). (Courtesy of Johns Hopkins University, Baltimore, MD.)

Pfund series

[atomic, nuclear] Atomic transition LINE SPECTRUM for hydrogen described by AUGUST PFUND (1879–1949) in 1924. The observed ATOMIC EMISSION wavelengths (λ), respectively FREQUENCY (ν), were found to adhere to a very pragmatic equation. The paradigm is based on the BOHR ATOMIC MODEL transitions between electron orbits (n_i): $\nu = \left(m_e e^4 Z^2 / 8 \epsilon_0^2 h^3 \right) \left[\left(1/n_1^2 \right) - \left(1/n_2^2 \right) \right]$, for $n_1 = 5$, where $m_e = 9.10939 \times 10^{-31}$ kg is the electron mass, $e = 1.60217657 \times 10^{-19}$ C is the charge equivalence of an electron [–] (or respectively PROTON [+]), the permittivity of free space $\epsilon_{EM0} = 8.85419 \times 10^{-12}$ C²/N m², PLANCK'S CONSTANT $h = 6.62606957 \times 10^{-34}$ m² kg/s, Z the number of charges in the NUCLEUS, and n_2 the respective originating electron orbits (*also see PASCHEN SERIES* for additional detail) (see [Figure P.50](#)).

Figure P.50 Pfund series.

pH

[biomedical, chemical] Parameter defining the level of acidity or alkaline exchange of hydrogen ions (H^+) for a substance. A pH less than 7 generally indicates acidic and greater than or equal to 7 alkaline. The scale stretches from 0 to 14. pH is defined as the LOGARITHM of the hydrogen ion ACTIVITY (a_{H^+}) in SOLUTION: $pH = -\log_{10} a_{H^+}$, where the hydrogen ion activity represents $a_{H^+} = f^*[H^+]$, where f represents the activity coefficient, this describes the hydrogen ion mibility. The pH was originally defined by the Danish chemist SØREN SØRENSEN (1868–1939) based on the hydrogen ion concentration ($[H^+]$): $pH = -\log_{10} H^+$. The pH of certain liquids for instance ranges from; urine: $pH \rightarrow 6.5\text{--}7$ range; BLOOD: $pH = 7.38\text{--}7.42$ range.

pH VALUE	H ⁺ CONCENTRATION	
–1	Hydrochloric acid (found in the stomach for digestion); also known as muriatic acid	Acid
0	Battery acid	
1	Concentrated sulfuric acid	
2	Lemon juice, vinegar	
3	Orange juice, soda	
4	Tomato juice, acid rain	
4.5–6.5	Black coffee	
5	Bananas	
6	Urine, milk	
7	Pure water	Neutral
7.40 ± 0.05	Blood	Alkaline
8	Seawater, eggs	
9	Baking soda	
10	Great Salt Lake, milk of magnesia	
11	Ammonia solution	
12	Soap solution	
13	Bleach, oven cleaner	
14	Liquid drain cleaner	

The acidity of the blood plasma is tightly regulated between $pH = 7.38$ and 7.42 . The body's pH HOMEOSTASIS is essential to the proper progress of chemical reactions, survival of the cells, and ultimately survival of the organism. The pH is tightly monitored through chemoreceptors measuring the H^+ concentration in both the blood plasma and the cerebrospinal FLUID. Two organs of particular importance to tight control of acidity are the lungs and the kidneys. Central and peripheral pH sensors are located throughout the mammalian body, in particular in the internal and external carotid (neck, leading to the brain), the aortic arch (right after the egress from the left ventricle of the HEART), and in the medulla of the brain. Even though the blood–brain BARRIER provides poor permeability to H^+ , the acidity of the brain is influenced by means of carbon dioxide (cellular METABOLISM waste product): $CO_2 + H_2O \rightleftharpoons H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$, carbolic ACID. Note that the brain cells are perfused by an extracellular fluid (ECF) that is independent from the blood flow. The function of the chemoreceptors is to mitigate changes to the pH by influencing the RESPIRATION, through inducing the release of buffer solutions, and by means of KIDNEY function as a residual effort. Buffers are for instance $H_2PO_4^{2-}$ and HCO_3^- , which bind to H^+ and can be released from cells and ECF. In all these mechanisms contradictions can arise, for instance the increase of carbon dioxide (partial pressure of CO_2 ;

subsequent lower pH) subsequently decreases the binding of oxygen to hemoglobin. The latter results in the release of additional oxygen in regions that are rich in carbon dioxide, the BOHR EFFECT (see [Figure P.51](#)).

Figure P.51 Litmus paper used to indicate the acidity of a substance.

Phagocyte

[biomedical, mechanics] Specialized biological CELL that uses PHAGOCYTOSIS for the removal of extracellular material that may be considered harmful (see [Figure P.52](#)).

Figure P.52 Illustration of how a phagocyte captures the content of, for instance, medication (i.e., pill).

Phagocytosis

[biomedical, mechanics] The active mechanism for biological CELL to ingest solid items. The CELL MEMBRANE forms a vesicle that wraps around the material on the exterior of the cell membrane and subsequently transports the encapsulated material to the interior of the cell. The consumption process is part of the classification of ENDOCYTOSIS, which also includes consumption of LIQUID defined as PINOCYTOSIS. Generally, the PARTICLE size is larger than 1 μm . Specialized cells call phagocytes uses phagocytosis for the removal of pathogens. On the MECHANICS of the selective restructuring of the lipid-protein bilayer (*also see CELL MEMBRANE*) (see [Figure P.53](#)).

Figure P.53 The process of phagocytosis in biological cells. This is an active cellular deformation process. The local surface tension is adjusted actively to “open-up” the wall for consumption.

Phantom

[acoustics, computational, electromagnetism, optics] Artificially constructed medium that has most of the essential characteristics representative of the real object that needs to be investigated, specifically with respect to the ENERGY in question; ELECTROMAGNETIC RADIATION, particle beam, acoustic WAVE. For instance, a tissue phantom for PHOTODYNAMIC THERAPY dosimetry investigations can be constructed of a watery solution with SCATTERING particles (e.g., lipid [soy] or POLYMER [polyester; or other materials, including metals] of specific size; scatterer dimension determines both the scattering coefficient and the scattering anisotropy factor) and absorbing particles (e.g., Indian ink) (see [Figure P.54](#)).

Figure P.54 The use of a phantom medium to illustrate the concept of a physics phenomenon, in this situation steam formation that is boiling water.

Phase

[acoustics, chemical, electromagnetism, fluid dynamics, general, geophysics, mechanics, quantum, solid-state, thermodynamics] Several particular definitions of phase are in use; geophysical phenomena, mechanics, material sciences, logistic processes, and thermodynamic processes. In material science and general PHYSICS, the phase indicates a location in a region of time and space, within which all physical characteristics of a medium, or a material, are fundamentally unvarying and uniform. In MECHANICS, the phase represents the angular fraction during a periodic process (e.g., sinusoidal) with respect to equilibrium at a chosen start time (i.e., the phase constant (ϕ) and the progression over time (ωt), pertaining to a rhythmic, HARMONIC MOTION: $\Phi = \Phi_0 \sin(\omega t + \phi)$, where $\omega = 2\pi\nu$ is the ANGULAR VELOCITY and $\nu = v/\lambda$ the frequency for a wave with wavelength λ under propagation velocity v . The frequency of the observation, WAVE, is of critical importance when comparing the respective phases. Two phenomena that are operating almost at the same frequency will experience INTERFERENCE at certain time frames when the respective wave crests match up, and this will generate a BEAT FREQUENCY of the combined phenomena. The beat frequency will be observable at the difference of the two frequencies: $\nu_{\text{beat}} = \nu_2 - \nu_1$, with respective AMPLITUDE $\mathcal{A}_R(t) = (\mathcal{A}_1 + \mathcal{A}_2) \cos\left\{2\pi\left[(\nu_2 - \nu_1)/2\right]t + \phi_i\right\}$; note that this only holds true for a deviation in the order of less than 0.25%, respectively less than 1 to several Hz, depending on several boundary conditions, including the MAGNITUDE of either wave phenomenon. A similar concept applies to the tuning fork used to tune a musical instrument. The phase of a wave phenomenon has a 360° or 2π recurrence, where 0 or 2π , respectively 360° , indicates complete in-phase, versus a phase difference between two events of 180° or π represents totally out-of-phase, or opposite phase. For waves the concept of superposition applies under all conditions.

Wave phenomena that are totally in-phase will provide a condition of **RESONANCE**, or amplification of the magnitude of the phenomenon, whereas totally out-of-phase characterizes cancellation. The phase difference is an indication how much difference there is in the “location” (in time and/or space, depending on the phenomenon or the specific **ENGINEERING** interests) of the respective crests of two waves of identical frequency. Generally, the phase of a wave will allow synchronization of events as well as imaging applications—coherence. Laser **LIGHT** by nature is coherent and hence in phase over the entire path of the emitted beam, extending over light-years. The phase of **ELECTROMAGNETIC RADIATION** is essential in the process of **OPTICAL COHERENCE TOMOGRAPHY** for instance. Other applications of phase related detection/sensing are based on the correlation between emitted and retrieved reflected waves in radar imaging of weather phenomena and objects in flight (e.g., airplanes), nondestructive testing (using electronic, optical, and acoustic mechanisms of action), **ULTRASOUND** imaging (**MEDICINE**), and radar detection of the velocity of an object, for instance used by law-enforcement agencies. In **ACOUSTICS**, the phase of a wave is predominantly determined by the dimension of the source, for instance a string on a cello or alternatively a **PIPE** organ. In **THERMODYNAMICS**, the phase represents the state of a medium: solid, **LIQUID**, gas, or plasma. In that regard, phase transitions refer to changes from liquid to **VAPOR** (vaporization) and solid to liquid (melting) and respectively for the reverse processes (condensation: vapor to liquid; **FREEZING**/congealing: liquid to solid), as well as solid to vapor (**SUBLIMATION**), and deposition: from gas to solid. Freezing is the phase change as a substance changes from a liquid to a solid. A **PHASE DIAGRAM** in thermodynamics illustrates the behavior of a medium as a function of pressure, temperature, and volume, specifically with respect to the exchange of heat. The **PHASE DIAGRAMS** usually illustrate the condition of a medium in a graph with the horizontal axis outlining the units of the independent variable considered in the study (abscissa, x -axis; Cartesian), either temperature or pressure, and the vertical axis the units of either the dependent variable in the study or in this case a second independent variable (ordinate, y -axis; Cartesian), the pressure. The angular phase of the process describes the stage in a distinct period of change or forming during the development of something; either a logistic course of action or a device design/manufacturing sequence of events. In a geophysical concept, the lunar phase describes the relative location of the **MOON** with respect to the **EARTH** under illumination by the **SUN** from a coordinate in space, providing a sequence of views of the Moon ranging from dark new moon to full disk full moon. The lunar phases range in appearance during eight key stages for its revolution around the Earth: new moon, waxing crescent, first quarter, waxing gibbous, full moon, waning gibbous, third quarter, and finally waning crescent (see [Figure P.55](#)).

(c)

Figure P.55 (Continued) Scientific use of the definition of phase (c) in illumination stages for the Moon.

Phase cancellation

[acoustics, electromagnetism, fluid dynamics, general, mechanics, quantum, thermodynamics] The moment at which two periodic phenomena that operate at the same frequency are in opposite PHASE with each other and cancel each other out in its entirety (see [Figure P.56](#)).

Figure P.56 Surface waves resulting from two perturbations in two different locations will result in merging waves where locations with opposing phase will cancel each other out yielding zero surface displacement.

Phase diagram

[chemical, computational, general, thermodynamics] Graphical representation of conditions used to illustrate at which point thermodynamically distinct phases can exist during equilibrium. The thermodynamic phase diagrams illustrate the phases of a medium under variable conditions of pressure, volume, and temperature, indicating the TRIPLE POINT (coexistence of LIQUID, VAPOR, and GAS phases at certain combination of pressure and temperature) and the critical point (the threshold temperature, when exceeded will result in a GAS PHASE for the medium regardless of the pressure) between vapor, liquid, and solid. More generally, the phase diagram illustrates the processes of FREEZING (SOLIDIFICATION)/melting, and vaporization/condensation,

while under certain circumstances the conditions for the formation of a plasma may also be included. Also referred to as PV-DIAGRAM, for pressure versus volume outline of the state of the medium, and as PT-DIAGRAM with respect to temperature (see Figure P.57).

Figure P.57 Phase diagram.

Phase encoding

[biomedical, computational, theoretical] Signals that carry information can be encrypted with encoding mechanisms ranging from AMPLITUDE, phase to frequency, in both analog and digital SIGNAL transmission. The process of amplitude modulation is found in AM-RADIO, whereas frequency encoding is used in FM-radio and television to name a few. In order to create a greater discrimination and added security to avoid accidental “listening-in” or “hijacking” personal information, additional mechanism of encoding need to be implemented, including the highly configurable phase encoding. The phase encoding can be embedded with a preprogrammed phase DRIFT that is geared to the “receiver” conditions, such as that used in mobile phones. In imaging the process of phase encoding is for instance applied in magnetic resonance imaging (MRI), where the phase of a MAGNETIC FIELD is configured through altering the phase of spins in one dimension by pulsing the *magnetic field gradient* along the intended dimension of interest prior to the acquisition of the signal. The magnetic field has three components in a Cartesian system, where under imaging conditions the three respective vectors will have the same chemical frequency shift, and will subsequently possess the same Larmor frequency when exposed to a uniform magnetic field. If the applied gradient in the magnetic field is directed along the x -direction, the three magnetic field vectors will precess at a frequency given by the RESONANCE equation, with respect to the direction of the applied external magnetic field. On the other hand, the phase ANGLE (i.e., phase encoding) of each respective vector is not identical. The phase angle in this case represents the angle between a reference axis, either the x - or z -axis. Note that the magnetization vector will need to be discontinued at the time the phase encoding gradient takes place to avoid convolution of information. There are three distinct phase angles in this example. The subsequent spatial reconstruction can be explicitly and precisely located by means of FOURIER TRANSFORM analysis. The ensuing MRI spatial RESOLUTION is a direct function of the number of phase encoding levels applied to the respective field gradients. In telecommunications, specifically data transfer and data storage, phase encoding uses a clock frequency to provide a tuning mechanism for the collection of the signal. One other application is also found in card-key reader and access code using RFID (radio-frequency identification). Phase encoding on a digital basis uses a line code that has no DC-components, in which the encoding can be identified by means of ensuring that each data bit has at least one transition that occupies the same time. The clock signal can in this manner be recovered from the encoded data. Phase encoding is also used in 10BASE-T Ethernet (IEEE 802.3 standard). Digital phase encoding can apply highly configured phase trains, with a phase pattern repeater for imbedding many different sources of information. Temporal phase encryption disqualifies the coherent addition of various pulses in the frequency domain. This in itself

provides a platform for reducing the signal power spectral density. Hence eliminating the need to transmit the signal within the bandwidth used by the handler in order to conceal information within the signal spectrally. Spectral phase encoding provides a mechanism for temporal spreading of the pulse sequence, resulting in a stealth-like temporal and spectral transmission. This process applied for instance to optical communications by means of fiber-optics. On a biomedical level, phase encoding is potentially used to indicate the location of the source of a signal transmitted through the nerves, nervous system and identified by the brain (phase encoding for a binary system is different than for an analog system, for instance using a phase shift for a “marker” pulse segment). Further decoding is with respect to the digitally encoded characteristics of the observation, such as COLOR, taste, etc., MAGNITUDE as well as the physical characteristic itself (touch versus pain, brightness versus pin/threat, etc.) where the encoding will first allow only the appropriate receptor (brain function segment, special dedicated functional areas in the brain for sensation, MOTION control and thought, in addition to lobes for “mood/character”) to collect the relevant data. The intensity/magnitude of any sensation is represented in the frequency aspect of the binary signal; higher frequency pulse train indicates stronger sensation. For instance, the EYE has three CONES for RED, green, and blue, but the communication process through many branches and matrices of nerve cells, synaptic junctions, and amplifier stations (one nerve exciting multiple downstream nerves) does provide an accurate PERCEPTION after an elaborate signal processing network. Furthermore, after damage to the nerve system, respectively the brain, under certain conditions other nerve paths and respective brain segment can “learn” to acquire the data and encode it, which may initially be flawed but can grow to a highly accurate representation varying per individual since biology is by far not an exact science and has a wide range of boundary conditions that influence the final outcome. Respectively, sometimes the biological encoding may not be intact or “perfect” by nature, for instance resulting in reduced perception or “signal confusion,” such as certain forms of colorblindness or the often learned behavior for flavor (e.g., dislikes, thresholds). Phase encoding is also known as Manchester encoding, developed by the University of Manchester, Manchester, United Kingdom (see Figure P.58).

Figure P.58 Conceptual representation of phase encoding.

Phase noise

[acoustics, electromagnetism, mechanics] Noise in general is SIGNAL that deviates from a well-defined spectral and AMPLITUDE configuration. Noise can be generated as the result of the phenomenon itself, creating harmonics and specifically harmonics that are not in sync with the primary WAVE, or have fluctuating amplitude for the respective orders as a function of time. Other sources of NOISE originate from the medium in which a signal is generated or through which it will travel, providing DISPERSION next to dampening effects, with different MAGNITUDE for different frequencies and spatially diverse. Specifically, crystals produce inherent noise due to the source properties pertaining to freedom of movement of the oscillator; mechanical constraints will automatically induce harmonics and dispersion effects. Thermal effects also provide a main cause for noise, due to collision interactions. Since noise contains components at multiple frequencies, the respective phases will have a random distribution, as well as the amplitudes will be randomly distributed over time and spectrally. Noise is described in statistical terms because its magnitude is constantly and randomly changing. However, one can assign an average amplitude (A) that can be expressed in root-mean-square (RMS) value. Phase noise has implication in both the FREQUENCY (ν) and TIME (t) domain. In particular, in the time domain it causes jitter in the acquired signal. In the frequency

domain, the phase noise contributes to a PHASE shift (ϕ_{random}): $A = \{A_0 + A_{\text{noise}}(t)\} \sin(2\pi\nu_0 t + \phi_{\text{random}})$. The signal will appear as a primary component with sidebands (*also see NOISE*) (see [Figure P.59](#)).

Figure P.59 Graphical representation of the phase noise spectral profile.

Phase rotation

[acoustics, computational, mechanics, theoretical, thermodynamics] In a polyphase system, the order of waveform sequences. In electrical applications, the power supply will have a specific PHASE associated with the alternating current ($I_i = I_{i,0} \sin(\omega t + \phi)$). In a three-phase system (high-voltage, high-power consumption electric motor design, e.g., crane), the three power supplies will have their own respective phases that will interact with each other inside the electric motor, allowing the MOTOR to rotate one way and when switching two of the phases it will reverse the direction. Operational process for three-phase alternator: PHASE SEQUENCE for proper operations; clockwise: Also described as phase “sequence.” Alternatively, in acoustic communications with one TRANSDUCER and multiple receivers, the collected phase at the respective receivers can be subject to DOPPLER shift or DISPERSION, creating a SIGNAL processing complexity due to the various signal phases related to the information transmitted for the single source, specifically pertaining to imaging (communications, scanner array). In particular, the use of a PHASED ARRAY in ULTRASOUND imaging relies on phase rotation to systematically build a three-dimensional IMAGE (see [Figure P.60](#)).

Figure P.60 Phase rotation for a three-phase generator, Crane using a three-phase electromotor.

Phase rule

[thermodynamics] Mechanism to determine the MAGNITUDE of the number of DEGREES OF FREEDOM (DF), respectively the variance of a chemical system, proposed by JOSIAH WILLARD GIBBS (1839–1903) in 1875: $DF = 2 + C_n + P_{\text{chem}}$, with C_n the number of constituents in the chemical mixture and P_{chem} the respective number of phases present within the system. The PHASE is defined as the part of a system that is chemically and physically homogeneous. The region confined to certain phase is bounded by a distinct interface with respect to other phases and can be physically separated from other phases. The phase rule defines the possible number of equilibrium situations for a system or chemical reaction. The phase rule has particular application in PHASE DIAGRAMS. For instance at triple points, all phases must coexist in the adjacent stability fields as well as at equilibrium lines (see Figure P.61).

Figure P.61 Graphical representation of the phase rule principles.

Phase sequence

[acoustics, computational, mechanics, thermodynamics] See PHASE ROTATION.

Phase space

[atomic, computational, nuclear] A graphical statistical representation space in which all possible physical and thermodynamic states of a system are outlined. Each possible state of the system in the phase space will have an assigned unique point. One example is the representation of location and respective momentum ($p = mv$, with the mass m at location x , traveling at velocity v) for all coordinates of the constituents of a system. The Hamilton operator (H) connects the location to the momentum, which can be observed dynamically, creating what can be considered a Hamiltonian flow in phase space. The VOLUME (V) in this phase space ($dV = dp_x dx$) is conserved: $(1/V)(dV/dt) = \nabla \cdot f(\eta_{\text{phase}}) = \partial/\partial x (\partial H/\partial p_x) + (\partial/\partial p_x)(-\partial H/\partial x) = 0$, where $\eta_{\text{phase}} = (x, p_x)$ represent the location (phase point) in phase space, and $\partial \eta_{\text{phase}}/\partial t = f(\eta_{\text{phase}}) = [\partial H/\partial p_x, \text{ and } -(\partial H/\partial x)]$ is known as the Liouville theorem. The mathematical concept of phase space was unknowingly introduced by the French mathematician JOSEPH LIOUVILLE (1809–1882) in 1838. Liouville's work was further refined

approximately in 1842 by the German mathematician CARL GUSTAV JACOB JACOBI (1804–1851), without a direct reference to space or phase, but with a consistent and working mathematical treatment. Additional work by LUDWIG EDUARD BOLTZMANN (1844–1906) in 1866 also references the concept of phase space with respect to his theory of gasses, introducing a new field of statistical MECHANICS (see Figure P.62).

Figure P.62 (a,b) Phase space for electroencephalogram (EEG) monitoring. Courtesy of Michel Le Van Quyen.

Phase transition

[computational, thermodynamics] Conversion between the three states of solid, LIQUID, and gas. The following phase transitions are recognized: liquid to VAPOR: vaporization; vapor to liquid: condensation; solid to liquid: melting; liquid to solid: FREEZING/congealing; solid to vapor: SUBLIMATION, and gas to solid: deposition. Additional PHASE transitions are recognized as conducting-to-superconducting, fluid-to-superfluid, as well as solid-to-solid transitions. With any phase transition, a LATENT HEAT is associated defining the total heat (Q) required to transform a mass (m); for instance for solid to liquid or vice versa the latent heat of FUSION L_f , providing $Q_f = mL_f$, respectively for vaporization L_v . Note that all these transitions are reversible. Two phases of the same single-component system in equilibrium have equal Gibbs free ENERGY ($G = H - TS$, where H represents the system enthalpy, T the temperature, and S the entropy). Phase transitions are categorized by the Ehrenfest classification. The order of the phase transition is defined based on the order of the lowest order derivative at the phase boundary involved in the transition, which changes discontinuously (*also see* SECOND-ORDER PHASE TRANSITION).

ORDER	GIBBS DIFFERENTIAL		CORRESPONDING CHARACTERISTICS		
First	S	V	S	V	
Second	$(\partial S/\partial T)_p$	$(\partial V/\partial T)_p$	c_p	β	K_p
	$(\partial S/\partial P)_T$	$(\partial V/\partial P)_T$			
Third	$(\partial^2 S/\partial T^2)_p$	$(\partial^2 V/\partial T^2)_p$	$(\partial c_p/\partial T)_p$ $(\partial c_p/\partial P)_T$	$(\partial \beta/\partial T)_p$ $(\partial \beta/\partial P)_T$	$(\partial K_p/\partial T)_p$ $(\partial K_p/\partial P)_T$
	$\partial^2 S/\partial T \partial P$	$\partial^2 V/\partial T \partial P$			
	$(\partial^2 S/\partial P^2)_T$	$(\partial^2 V/\partial P^2)_T$			
S , Entropy	P , Pressure	V , Volume	c_p , specific heat under constant pressure	$\beta = 1/\kappa_b T$ $\kappa_b = 1.3806488 \times 10^{-23}$ $\text{m}^2 \text{kg/s}^2 \text{K}$, the Boltzmann constant	K_p , equilibrium constant: $\ln(K_p(T))$ $= -(1/RT) \sum v_i \mu_i^0(T)$; $R = 8.3144621(75) \text{ J/K mol}$ The gas constant; v_i the stoichiometric coefficient $\mu_i^0(T)$ the chemical potential for component $\square_i$

Phase velocity

[acoustics, atomic, mechanics, nuclear, optics] Speed at which any fixed PHASE of the cycle of a WAVE is displaced: $v_p = \omega/\kappa = \lambda v$, where $\omega = 2\pi v$ is the ANGULAR VELOCITY of a single wave form operating at frequency v , $\kappa = 2\pi/\lambda$ the wavenumber, and λ the associated wavelength. This stands in comparison to “group velocity” and “wave velocity.” For a composite waveform, the individual frequencies will experience DISPERSION, causing deformation in the wave pattern.

Phase-locked loop

[electromagnetism, theoretical] A closed-loop phase-based frequency control feedback mechanism, locking in on the primary WAVE. The phase-locked loop (PLL) is an electronic circuit designed for PHASE sensitive detection, for instance in communication (e.g., RADIO), of electrical phase difference between the received input signals and the output signals of a tunable oscillator. The tuning mechanism relies on continuously adjusting the oscillator frequency of the receiver tuner to match the phase of the frequency of the input SIGNAL, hence reconstituting the acquired signal with reduced NOISE. In communications, the PLL modulates and respectively demodulates the collected signal to provide uninterrupted reception with few distortions (breaks in communication) and low noise. The PLL can be voltage controlled or current driven, using the CARRIER frequency of the source as the control mechanism for accurately matching up the receiver signal. The tuning oscillator (e.g., crystal-controlled reference oscillator; voltage controlled oscillator: VCO) is approximately tuned to the intended frequency by means of component value selection (e.g., RC value for

recovery time). With the help of a phase comparator circuit the receiver seeks out the frequency and will lock onto the desired frequency. The phase detector produces a voltage that is proportional to the phase difference between the input and reference signal, where it is used to provide a reduction in difference feedback in the loop filter. In radio reception, this principle is achieved by the DEMODULATOR (FM-radio). The combination of PLL, VCO, reference oscillator, and phase comparator (phase detector that compares the phase of the signal derived from the oscillator to the input signal) forms what is called a frequency synthesizer.

Phase-only imaging

[acoustics, imaging, optics] Imaging technique based on using only the PHASE information of the AMPLITUDE in a complex formation of a WAVE. One specific application of phase-only imaging is applied to HOLOGRAPHY. Phase-only imaging has a reduced bit rate over conventional imaging and requires less data storage. It will still provide high-resolution images.

Phased array

[acoustics, biomedical, computational, electronics, geophysics, imaging] Source (e.g., piezoactuator and ANTENNA) composed of a multitude of radiating ELEMENTS each equipped with a PHASE shifter to provide a predetermined phase difference between respective, individually wired, elements. The consecutive phase shift between elements can turn the direction of a plane wave without physically changing the location of the emitters, and provide a focusing mechanism: BEAM FORMING. The beam steering ANGLE (θ_s) is directly based on the phase difference ($\Delta\phi$), the intersource spacing (d), and the source wavelength (λ): $\Delta\phi = 2\pi(\sin \theta_s / \lambda)d$. When performing a scan, a sweep may be performed by changing the phase according to $\exp[i2\pi(\sin \theta_s / \lambda)d]$. The detection mechanism uses the original phase difference to exclude detection from other respective sources, and additionally relies on INTERFERENCE for contrast enhancement. In ULTRASONIC IMAGING (nondestructive testing, medical imaging), this device operation can be used in sweep mode, where the phase angle is altered in a predetermined pattern to perform a sector scan. The sweeps are performed at high frequency (kHz). Because of the inherent semi empirical approach the decoding will require a look-up table for IMAGE reconstruction (see Figure P.63).

Figure P.63 Diagram of phased array, such as those used in ultrasonic imaging.

Phasor

[atomic, computational, general] Graphical representation of two quantities that are linked by a time-dependent relationship (e.g., alternating, harmonic), potentially resulting in a delay in PHASE between the two oscillatory phenomena (e.g., current in an electronic circuit versus voltage; presented as a function of the phase ANGLE between the two). Alternatively, the depiction of a rotating vector from a sinusoidal phenomenon as a function of ANGULAR VELOCITY (ω) with AMPLITUDE A . A phase vector. Also described as the Smith chart in electronic design.

Phosphorescence

[atomic, optics, solid-state] The ability of a substance to semi autonomously emit light (photoluminescence), without the requirement of excitation by ELECTROMAGNETIC RADIATION as under FLUORESCENCE. Phosphorescence may be fueled by chemical processes. During biological emission of light, such as that found in bacteria, squids, blooming phytoplankton, and certain fish, the pigment flavin, LUCIFERIN, is oxidized in the presence of an enzyme luciferase. The luciferase is also produced by the organism itself. One particularly well-known form of BIOLUMINESCENCE is found for the fire-fly. Phosphorescent substances have the ability to store up light and release it gradually. The notion of a metastable state explains this. If the molecules of the substance can get from the GROUND STATE to a metastable state, and if the metastable state can slowly DECAY back to the ground state via PHOTON emission, then we have phosphorescence. The mechanism of action of phosphorescence relies on the excited metastable triplet state, with respect to the ground state that is a SINGLET STATE. The TRIPLET STATE is defined for a MOLECULE containing two unpaired electrons that can migrate between three spin-states. Each of the electrons is subject to spin-orbit coupling; however, each with respective strengths s_1 and s_2 , which will subsequently precess at different rates. A SPIN triplet consists of a set of three QUANTUM states, each with respective total spin $S = 1$. The MAGNITUDE of the resultant spin vector, $s_1 + s_2$, will tip back and forth between quantum states $S = 0$ and $S = 1$. Hypothetically, the system could consist of just a solitary elementary “spin 1” PARTICLE, of undefined size. The active molecules can be raised from the ground state by ENERGY absorption (chemical, electrical, electromagnetic) to excited singlet states. Most frequently, they will immediately return to the ground state, emitting a photon (fluorescence). Under certain conditions (chemical, external fields, etc.), a nonradiative processes will raise the state to a less energetic triplet state. Once these molecules reach the lowest triplet state, they will remain in this state for an undetermined time. Under the low-probability triplet-singlet conversion processes, the molecules will emit LIGHT. The total energy stored in the molecule includes nuclear processes including VIBRATION and rotation of the nuclides as well. Under the assumption that the excited singlet state is close in energy to a triplet state, the molecule can make a singlet-triplet transition, exchanging energy with the environment through the vibrational modes (i.e., vibrational relaxation). After that it will decay to the bottom triplet state, followed by a triplet-singlet transition. The triplet-singlet and singlet-triplet transitions, in fact, both violate the $\Delta S = 0$ SELECTION RULE, AND are hence relatively slow (seconds–minutes, compared to a nanosecond scale and less for fluorescence). However, the $\Delta S = 0$

selection rule applies only to DIPOLE transitions, meaning that the phosphorescent, “glow-in-the-dark” objects in fact do not violate any laws (see [Figure P.64](#)).

Figure P.64 Phosphorescent jelly fish.

P Phosphorus (phosphor) ($^{30}_{15}\text{P}$)

[atomic, chemical, nuclear, solid-state] ELEMENT described first in 1669. Nonmetal, polyatomic. Phosphorus is found primarily in three forms: white, violet, and red, but is never discovered as pure substance due to its highly reactive nature (always bound, oxidized). Phosphorus is particularly known for its ability to emit visible LIGHT under the influence of incident short-wavelength ELECTROMAGNETIC RADIATION as well as certain energetic PARTICLE radiation. Electron bombardment provides the mechanism of action for visible light emission in photographic X-RAY detectors as well as the IMAGE formation on the face of the old-fashioned CRT (CATHODE ray tube) television/monitor screens (also found in oscilloscopes). Phosphorus is used in many

everyday chemicals, ranging from cleaning supplies to pesticides to nerve agents and in matches. Note: only the white phosphorus can oxidize and form light, not the red or violet phosphorus (see [Figure P.65](#)).

Figure P.65 Phosphorus as used in matches.

Photinus-luciferin 4-monooxygenase

[biomedical, chemical, optical, thermodynamics] Biological enzyme that is closely linked to the formation of ADENOSINE TRIPHOSPHATE (ATP, cellular biological renewable ENERGY form in macromolecule) that emits LIGHT at a very narrow bandwidth of around 562 nm. One particular form of emission is under chemical OXIDATION excitation: Photinus luciferin + O₂ + ATP Mg oxidized Photinus luciferin + CO₂ + AMP + diphosphate + 562 nm light, where Mg is a magnesium cofactor (chemical catalyst), and AMP represents adenosine monophosphate.

Photoacoustic microscopy

[acoustics, biomedical, imaging, optics] Hybrid imaging technique that relies on the excitation of phonons inside a medium by means of selective absorption of photons, photoacoustic effect. Photoacoustic imaging is nondestructive, high RESOLUTION, and has deep penetration. The acquired spatially resolved acoustic spectrum will yield information about the configuration of the local elastic moduli (also known as PHOTO-ACOUSTIC IMAGING). Photoacoustic imaging is based on the principle of LIGHT absorption that will generate elevated temperatures. Based on the Boyle–Gay–Lussac law, higher temperatures will lead to increased pressure, and from this it can be seen that a net increase in local volume can also be expected. Under pulsed laser irradiation, the short duration temperature rise can produce mechanical longitudinal shock waves. Combining the fact that light will penetrate deep into a medium and the localized generation of acoustic SHOCK WAVE, will produce an imaging system that may surpass the attributes and characteristics of both optical and acoustical imaging. The photoacoustic effect is described based on three equations, each with a range of unknowns. The first equation is the EQUATION OF RADIATIVE TRANSFER, describing the light distribution inside the target medium resulting from the pulsed light irradiation and the potentially nonlinear optical effects under these conditions. The resulting temperature generation and associated thermal effects (damage) are described by the heat equation. Finally, the EXPANSION with rising temperature and resulting acoustic wave propagation is defined through the WAVE EQUATION; in three dimensions with changing

boundary conditions due to the thermal effects and transient nature of the compression. Solving this problem analytically relies on clever choices for approximations, when possible. Generally during pulsed laser photoacoustic imaging the light is delivered over periods in the nano or femtosecond time frame, which creates several theoretically advantageous conditions. The equation of radiative transfer will incorporate the source function $S(\vec{r}, \vec{s})$, defining the laser beam incident on the medium under investigation, assuming standard Gaussian characteristics: $S(\vec{r}, \vec{s}) = I_0 \text{EXP}[-2r^2/w^2]$, where I_0 is the radiance at the center of the beam, w the beam waist, and r the radius from center of the beam. The time-dependent equation of radiative transfer can generally be solved by separating the anisotropic radiance in a direction-dependent term next to a diffuse term: $L(\vec{r}, \hat{s}, t) = (1/4\pi)\Psi(\vec{r}, t) + (3/4\pi)\Phi F(\vec{r}, \hat{s})$. Here, the symbol F defines the direction-dependent (i.e., diffuse) radiance. The fraction of ENERGY scattered to that removed from the radiance stream is indicated by the albedo: ω , for pure absorption $\omega = 0$, while for totally elastic, conservative SCATTERING $\omega = 1$, which is a function of optical depth. The diffuse fluence rate can be calculated based on the

DIFFUSION approximation of the equation of radiative transfer as

$(1/c)(\partial \bar{L}(\vec{r}, t)/\partial t) - \vec{s} \cdot \nabla \bar{L}(\vec{r}, t) + [\mu_a(\vec{r}) + \mu_s(\vec{r})]\bar{L}(\vec{r}, t) - \mu_s(\vec{r}) \int_{4\pi} p(\vec{s}, \vec{s}') \bar{L}(\vec{r}, t) d\Omega' = \bar{S}(\vec{r}, \vec{s})$. Under the preferential short pulse conditions, the source $\bar{S}(\vec{r}, \vec{s}, t)$ function for the laser pulse can be written as

$\bar{S}(\vec{r}, \vec{s}, t) = \delta(\vec{r})\delta(\vec{s})\delta(t)$; this is specifically allowed due to the fact that the thermal RELAXATION TIME is much longer than the pulse duration. Additionally, the SOLUTION for the equation of radiative transfer can be found under these conditions as a FOURIER SERIES. For example, using the speed of light

($v = 299792458/n_2$ m/s, n_2 the index of refraction for the medium [$n_2 = 1.35$ water]), within a laser pulse duration of 100 fs, the cluster of irradiating photons can travel approximately 22 μm . Generally, in a turbid medium there will be isotropic scattering, resulting in a significant DISPERSION. However, due to nonlinear effects and long wavelength (in the RED and near INFRARED), the scatter will be primarily in the forward direction with a scattering anisotropy factor of $g > 0.95$, providing only a slightly diverging beam. On the thermal aspects, assuming an output energy of only 9 nJ (commonly found for Q-switched lasers), the peak energy density will be 0.0076 J/cm², or 760 kW/m², heating up a focal volume. Generally, under these short-pulse conditions, only a slight temperature rise will be seen, avoiding vaporization and, depending on Young's modulus of the medium, also cracking can be avoided. In rigid media such as teeth, the potential for cracking under "long" pulse duration may still exist. The heat resulting from the laser light absorption will flow in the direction of any temperature gradient inside the sample. The steeper the temperature gradient, the more efficient the conversion from optical to acoustical energy. The instantaneous local temperature rise of the medium under the absorption of light is given by $\Delta T = \mu_a L / \rho C_p$. The temperature rise is directly proportional to the absorbed local light fluence rate $\mu_a L(\vec{r}, \vec{s}, t)$ divided by the local SPECIFIC HEAT C_p times the density ρ , where $L(\vec{r}, \vec{s}, t)$ is the local radiance of light, and $\mu_a(\vec{r}, \vec{s}, t)$ is the optical absorption coefficient for the medium as a function of location, direction of propagation, and time. The temperature development $T(\vec{r}, t)$ can be calculated from the heat equation, ignoring the influence of flow of the medium itself, or through the presence of irrigation channels (which will be BLOOD vessels in biological media). The heat equation is written as $\nabla(\kappa \nabla T(r, t)) = \rho C_p \left[(\partial T(r, t)/\partial t) + \tau (\partial^2 T(r, t)/\partial t^2) \right] - \mu_a L(r, t)$, where κ is the THERMAL CONDUCTIVITY and $\alpha_T = \kappa / C_p \rho$ is the thermal DIFFUSIVITY. In order to assess the full impact of the thermal LONGITUDINAL WAVE the thermal relaxation time $\tau = 1/4\kappa\mu_a^2$ needs to be considered. For ultrashort laser pulses the thermal relaxation is in the order of $\tau_T \approx 1 \mu\text{s}$. Any event shorter than the thermal relaxation time can be considered QUASI-STEADY STATE, which is the case for femtosecond laser pulses allowing the time component of the source function to be approximated by a Delta distribution. As a result the second-order terms in the mathematical description, with respect to time, become negligible.

The temperature distribution can hence be modeled by the HEAT TRANSFER equation as

$\nabla^2 T(\vec{r}, t) - a^2 [\partial T(\vec{r}, t)/\partial t] = -[S(\vec{r}, t)/\kappa]$, with boundary conditions $T(\vec{r}, 0) = T_0(\vec{r})$. The temperature solution follows in terms of GREEN'S FUNCTION ($G(x, t; \xi, \tau)$): $T(\vec{r}, t) = \int_0^t \int_V G(x, t; \xi, \tau) f(\xi, \tau) d\tau dV(\xi) - a^2 \int_V G(x, t; \xi, 0) T_0(\xi) dV(\xi)$, where $f(\xi, \tau)$ represents the heat source, modeled as a spatial

GAUSSIAN DISTRIBUTION $f(\xi, \tau) = -[(1-R)/\kappa\tau_p] \mu_a J \exp[-\mu_a \xi] \exp[-2\rho^2/\omega^2] \delta(t)$, where $\omega(\xi) = \omega_0 [1 + (\lambda(\xi - \xi_0)/\pi\omega_0^2)^2]^{1/2}$, R is the surface reflectivity, J is the laser FLUX (J/cm²), ω is the beam radius (cm), ξ_0 is the location of the minimum waist, λ is the wavelength, and τ_p is the laser pulse width. Under the short time approximation, the heat source is a POINT SOURCE with solution for the Green function:

$G(x, t; \xi, \tau) = -[a^2/4\pi(t-\tau)]^{3/2} (1/a^2) \exp[-a^2|\vec{r}-\vec{\rho}|/(t-\tau)]$, where $\vec{\rho}$ is the radius in the

“Greens-medium.” This yields the solution for the temperature under femtosecond laser-pulse RADIATION as $T = T_0 + (c_2 \sqrt{\pi} d_1 / 4 b_1^{3/2}) \exp[d_1^2 / 4 b_1]$, using the following abbreviations: $b_1 = (a^2 / 4t) + (2 / \omega^2)$, $d_1 = a^2 r / 2t$ and $c_2 = (1 - R) \mu_a J e^{-\alpha z} \exp\{-a^2 r^2 / 4t\} / 2 \sqrt{\pi t a r \kappa \tau_p}$. Two particular cases can be distinguished for the conditions of the media: (1) absorption > scattering (black-body); (2) scattering > absorption. For a “black-body,” all the light emitted by the laser will be absorbed on the surface of the medium, negating the need for solving the RADIATIVE TRANSFER equation. Introducing the thermal relaxation length: $\ell_T = \tau_T v_{th}$, where v_{th} is the thermal propagation velocity of the medium; the thermal DIFFUSION LENGTH $\ell_D = \sqrt{2(\alpha_T / v_{laser})}$, where v_{laser} is the laser repetition rate. All these conditions provide the platform for a confined process, both spatially and temporally. It can be shown that under confinement the THERMAL EXPANSION length will be much smaller than the diffusion length. Additionally, the thermal diffusion length is also smaller than the thermal relaxation length. These conditions provide the simplification that the second-order derivatives in most equations will become zero. This can be verified by making Taylor expansions for all the parameters, which yields infinitesimally small second- and higher-order terms. As a result the thermal diffusion/propagation can be neglected in the heat equation, which can be shown to hold true after the Fourier expansion of the quadratic initial heat equation. The heat equation hence reduces to $\rho C_p (\partial T / \partial t) = \mu_a L(r, t) \delta(t)$. The third declaration describing the temperature impact on the displacement and as such the longitudinal pressure WAVE is defined based on the medium parameters, including Young’s modulus E and the cubic expansion coefficient β (which is three times the linear expansion coefficient: 3α) delivering the displacement u as $\rho (\partial^2 u / \partial t^2) - [E / 2(1 + \nu_p)] \nabla^2 u - [E / 2(1 + \nu_p)(1 - 2\nu_p)] \nabla (\nabla u) = E\beta / 3(1 - 2\nu_p) \nabla \theta$. The parameter ν_p represents the Poisson ratio, the ratio of the transverse contraction strain to the longitudinal extension strain in the direction of the stretching force: $\nu_p = -\epsilon_{trans} / \epsilon_{longitudinal}$. The Poisson ratio is a material constant. In the “far-field” theoretical analysis of the ULTRASOUND photoacoustic IMAGE formation, the following assumptions will be made. These conditions will subsequently be adjusted and refined based on the observed deviations from these approximations (requiring an iteration process based on the lack of knowledge of the real local parameters; deviating from the assumed conditions): (1) All calculations are performed in the Fraunhofer region, that is, in the far field; (2) in the far field the waves can be treated as plane waves; (3) the square of the received acoustic AMPLITUDE is directly linearly proportional to the scattered energy; (4) the scattered acoustic longitudinal pressure wave pattern is weak relative to the “photothermal” generated instantaneous pressure. The pressure wave may be converted into displacement, since the pressure is directly proportional to the square of the displacement. The medium will oscillate with a local RESONANCE FREQUENCY (ν) that is defined by the characteristic length of the confined segments under consideration, the value of Young’s modulus (E_Y), and the local density distribution can be expressed as $\nu = C \sqrt{E_Y / \rho} (d / w \times b)$, with d the depth, w the width, and b the height of the structure of the medium. C denotes a constant that is a function of the MOMENT OF INERTIA (I) of the structure; alternatively, $\nu = A \sqrt{(E_Y I / m_\ell L^4)} \cong A' \sqrt{(E_Y / \rho L^2)}$, where L represents the length of the sides of a cube of the medium, m_ℓ is the mass per unit length, and A is a constant that depends on the mode of excitation. The use of the moment of inertia is justified since during the tissue expansion process a VORTEX will be formed. With respect to the vortex formation, there will be strain due to the change in volume (ΔV) with respect to the initial volume (V): $\epsilon = \Delta V / V$. This is inherently linked to the temperature jump, as described by the volume expansion coefficient: β , $\Delta V = \beta V \Delta T$, giving $\epsilon = \beta \Delta T$. The stress in the medium equals the force per unit area, which by definition describes pressure. Hence the pressure associated with this strain is expressed as $P = -K_{bulk} \epsilon$, where K_{bulk} represents the bulk modulus that specifies the pressure per unit strain. The photoacoustic wave equation in the medium resulting from the light absorption can be derived from the momentum equation, the EQUATION OF CONTINUITY, and the EQUATION OF STATE. The three equations reduce to the following three conditions: $[\partial \rho(\mathbf{r}, t) / \partial \tau] + \nabla \bullet [\rho \mathbf{V}(\mathbf{r}, t)] = -\int_0^h S(\mathbf{r}, t) / \mathbf{r}^2 \delta \tau$, $[\beta(\mathbf{r}) / \rho_0 C_0^3] \rho [\partial V(\mathbf{r}, t) / \partial \tau] - (V(\mathbf{r}, t) \bullet \nabla) V(\mathbf{r}, t) + \nabla \bullet P(\mathbf{r}, t) = \nabla S(\mathbf{r}, t)$, and $P(\mathbf{r}, t) = K \rho^q$. Here, $V(\mathbf{r}, t)$ is the displacement velocity and $P(\mathbf{r}, t)$ is the acoustic pressure amplitude of the primary (ultrasonic) wave. The acoustic propagation resulting from photoacoustic excitation and the associated imaging aspects are very similar to ULTRASONIC IMAGING. The main difference with ultrasound imaging is that under photoacoustic imaging the acoustic source is less well defined and requires specialized sensory placement and SIGNAL acquisition design techniques to gain access to the three-dimensional information. The initial pressure $P_0(\mathbf{r}, t)$, resulting from laser absorption is defined as $P_0(\mathbf{r}, t) = G_r K \beta [\mu_a \tilde{L}(\vec{r}, \vec{s}, t) / \rho C_p]$. Using the correction factor, G_r , which expresses the fraction of thermal

energy from the absorbed light that is converted into mechanical expansion. With photoacoustic imaging, soft biological media such as blood vessels can be mapped. Frequently, ultrasonic imaging of soft tissues in biology required the use of a chemical being inserted into the patient as a contrast enhancement that may become obsolete under photoacoustic imaging. Other diagnostic applications are in thin-film thickness determination and associated quality control in semiconductor manufacturing and the automobile and airplane industry.

Photobiological process

[biomedical, chemical, optics, thermodynamics] Light mediated biological/biochemical effect including the PHOTOSYNTHESIS in plants and animals, as well as photoperiodism, phototaxis, and phototropism. A very special class is VISION. Other extended applications are found under LOW-LEVEL-LIGHT THERAPY (LLT).

Photobleaching

[biomedical, chemical, optics] The optical modification of the electromagnetic characteristics of a MOLECULE. Often photobleaching involves the destruction of dyes, or the SATURATION of the absorption with resulting decrease in SCATTERING of LIGHT or specifically the reduction or extinction of fluorescent transitions. Photobleaching indicates the temporary loss of a fluorophore to fluoresce as a result of PHOTON-induced chemical damage and on a molecular level the covalent modification. The covalent modification consists of the saturation of the transition from an excited SINGLET STATE to the excited TRIPLET STATE. During the FLUORESCENCE process, fluorophores may be induced to interact with another molecule and inadvertently produce irreversible covalent modifications. The triplet state is relatively long-lived with respect to the energetic singlet state. Hence excited molecules will experience a much longer time frame to endure chemical reactions with environmental constituents. The average number of excitation and emission cycles allowed for a particular fluorophore is generally dependent on the molecular structure as well as the local environment. Certain fluorophores may bleach rapidly after emitting merely a few photons. Other molecules can perform millions of fluorescence cycles before bleaching. The deliberate extinction of fluorescence with the ensuing fluorescent recovery is one particular application of photobleaching used for physiological imaging in biological applications, specifically with respect to the protein binding analysis for the CELL MEMBRANE; called fluorescence recovery after photobleaching (FRAP) imaging (*also see* "FADING").

Photocathode

[electronics, imaging] Light sensitive negatively charged ELECTRODE that releases electrons when ELECTROMAGNETIC RADIATION is incident, such as that used in the design of a PHOTOMULTIPLIER TUBE. The electrode may be treated with specific materials to increase the sensitivity to LIGHT and encourage the PHOTOELECTRIC EFFECT on the surface, releasing an electron in free space.

Photochemical effect

[biomedical, chemical, optics] In VISION it has been shown that in contrast to the slow overall phenomenological mechanism of vision there are events in ROD and CONE sensibility that take place in the femtosecond and even picosecond range. The vision experience itself is however in the 20–100 Hz range for the various species. The physiochemical process of the PHOTOCHEMICAL EFFECT in the RETINA is in the same range as the PHOTOELECTRIC EFFECT.

Photochemical reaction

[biomedical, chemical, optics, thermodynamics] *See* LOW LEVEL LIGHT THERAPY.

Photocoagulation

[biomedical, optics] The conversion of PHOTON energy into MECHANICAL ENERGY (i.e., THERMAL ENERGY). The process describes the thermal denaturation of proteins to kill cells, either unwanted or potentially harmful, by means of destruction of the cellular membrane or the NUCLEUS of the CELL. The initial attempts

of the clinical use of photocoagulation can be traced back to the eighteenth century, by means of reflecting sunlight. Sunlight was channeled from the roof of the hospital in the operating rooms by means of mirrors and lenses. Prior to that, the healing potential of LIGHT was used by the Egyptians and Greek around the beginning of the western calendar. Other use of bright broad-band light such as the incandescent light or even still sunlight for clinical applications was in use for welding detached retina in the EYE, specifically in response to retinal detachment in diabetics in the early twentieth century. Other applications, also in the eye (primarily lending itself due to its optical transparency), were for the treatment of intraocular tumors. With the introduction of laser light, optical treatment procedures became more proficient due to the potential for selecting the most appropriate wavelength, resulting in minimized peripheral damage. The photocoagulation process specifically relies on the conversion of photon energy in thermal energy. The light absorption in the medium is a direct function of the light distribution as a function location with a tissue volume on a three-dimensional pattern, calculated using the TRANSPORT EQUATION or EQUATION OF RADIATIVE TRANSFER. Examples of other specific application of photocoagulation are wrinkle reduction/removal, tattoo removal, hair removal, and the removal of port-wine stains on human SKIN, and thermal superficial cancer tissue removal next to nonthermal deep cancer treatment (*see* PHOTODYNAMIC THERAPY), while minimizing the formation of scar tissue resulting from thermal burns to the peripheral tissues. Other applications are in tissue welding, providing an elegant manner for wound closure. Tissue welding is gaining popularity in the treatment of vascular diseases by a transcatheter approach. One particular application of vascular tissue welding is in anastomosis, joining vessels together that re-route the BLOOD flow, for instance in solving poor CIRCULATION in the legs or for SHUNT application in the arm, to be used during the process of connecting a patient to an external filtration system during KIDNEY dialysis. There are a number of ways to perform tissue welding: (1) through photothermal heating of the tissue itself, (2) by means of a solder or a photoactivated adhesive, or (3) by combining a LIQUID solder and a solid solder. Commonly used LIQUID solder agents are ALBUMIN and blood. Solid solders include insertion of biodegradable POLYMER thin films. To enhance the photoselective coagulation process, dyes can be used to achieve wavelength selective absorption. Direct laser welding relies on coagulating tissue proteins. The main advantage is that the tissues repair fast, with little or no foreign body reaction, and generally the seals are watertight. Disadvantages may be low acute strength, compared to a suture, and thermal damage to the tissue. The use of CHROMOPHORE-enhanced protein “solders” can augment the welding process, improving acute wound strength. Solders include polymers such as the biodegradable PLGA (polylactic-co-glycolic acid) as well as a liquid albumin solder. Additionally, the protein cross-linker genipin added to albumin solder results in a stronger tissue weld. Other welding agents are indocyanine green doped albumin (derived from bovine serum colored green to enhance absorption at the near INFRARED wavelengths used). Especially in vascular welding there is a frequent need for solder. Other factors involved in the welding efficiency are the thickness of the media d and the absorbed laser energy over the duration of exposure t . Before getting into the photothermal concepts, two definitions need to be introduced: enthalpy and entropy. Enthalpy H defines the energy of the chemical bonds between the atoms that constitute the molecules within the system. The entropy of the system is defined by the change in INTERNAL ENERGY divided by the temperature of the system at the time, as $dS = dQ/T$. The FIRST LAW OF THERMODYNAMICS postulates that energy cannot be destroyed nor generated. The work done on a system combined with the administered heat hence r is the temperature in kelvin and results in a change in internal energy: $dU = dQ - dW$. The laser/light energy deposited in the tissue will be absorbed and hence raise the local temperature. The energy deposition as well as the temperature rise can induce chemical reactions by means of changing the enthalpy of a system. The biological system consists of the atoms that form the complex molecules providing the building blocks of amino acids, carbohydrates, fats, and proteins. The deposited light energy is considered the reaction enthalpy, where the change in enthalpy is the final system enthalpy minus the enthalpy of the initial state of the system. TEMPERATURE EFFECTS OF LIGHT-TISSUE INTERACTION: the amount of photon energy conversion into thermal energy in the propagation process for the light in tissue is based on the absorption coefficient and the total attenuation coefficient. The locally generated temperature rise will result in heat flow due to a thermal gradient. The HEAT TRANSFER Q can be calculated at any given point in the tissue based on the local temperature gradient $\Delta T/\text{length} = [(d/dx) + (d/dx) + (d/dx)]T = \nabla T$, yielding $Q = -\kappa_T [(d/dx) + (d/dx) + (d/dx)]T = -\kappa_T \nabla T$, where T is the temperature in kelvin and κ_T is the THERMAL CONDUCTIVITY, on average $0.5 \text{ W m}^{-1} \text{ K}^{-1}$ for

water-based tissue. This heat transfer process is time dependent: $\rho c_V (\partial T / \partial t) = \nabla (k_T \nabla T)$, where ρ is the tissue density, for most tissues it is $1.04 \times 10^3 \text{ kg m}^{-3}$, and c_V is the heat capacity, approximately on average $3.7 \times 10^3 \text{ J kg}^{-1} \text{ K}^{-1}$. Incorporating the laser heat source q resulting from the light absorption gives $\rho c_V (\partial T / \partial t) = \nabla (k_T \nabla T) + q$, where q equals the rate of energy deposited in a volume of tissue cells, which is the local fluence rate (i.e., the location- and time-dependent light distribution) times the local absorption coefficient $\mu_a L(r, \theta, z)$. Additionally, in a full analysis the heat transfer resulting from blood perfusion should be included due to the abundance of blood vessels in all living tissues. Including blood perfusion in the energy balance for heat will incorporate the flow rate of the blood ω_b , in $\text{m}^3 \text{ kg}^{-1} \text{ s}^{-1}$; the density of the blood ρ_b ; the SPECIFIC HEAT of blood c_b ; and the heat exchange between the heated tissue and blood is based on the temperature difference between the blood and the surrounding tissue: $T - T_b$, to yield a blood flow heat loss as $-\omega_b \rho_b c_b \rho (T - T_b)$. Combining all the characteristics and phenomena describing the tissue temperature evolution as a function of time an expression can be obtained, known as THE HEAT EQUATION, respectively bioheat equation: $(\partial T / \partial t) = (1 / \rho c_V) [q + k_T [(\partial^2 / \partial x^2) + (\partial^2 / \partial y^2) + (\partial^2 / \partial z^2)] T - \omega_b \rho_b c_b \rho (T - T_b)] = (1 / \rho c_V) [k_T \nabla^2 T - \omega_b \rho_b c_b \rho (T - T_b) + q]$. In the process of raising the tissue temperature, other phenomena will take place, such as coagulation and EVAPORATION, which are both heat sinks that need to be accounted for. The coagulation process encompasses both a temperature rise and a PHASE TRANSITION. The phase transition for coagulation has a LATENT HEAT that is tissue specific: h_{coag} and is expressed in J kg^{-1} . The heat loss due to coagulation, Q_{coag} , is a direct function of the coagulated tissue volume V_i and the tissue density ρ , providing the coagulated tissue mass, defining $Q_{\text{coag}} = h_{\text{coag}} \rho V_i$. The heat loss due to evaporation is defined by the rate of water loss. Note that for cosmetic surgery the material under consideration may be either partially composed of fat or solely, with its own thermodynamic characteristics. The heat loss due to evaporation is the rate of evaporation multiplied by the latent heat of evaporation (water $h_{ev,W} = 2.26 \times 10^6 \text{ J kg}^{-1}$), which yields $Q_W = V_W (\rho_{W,\infty} - \rho_{W,S}) h_{ev,W}$, where V_W is the volume of evaporated water, $\rho_{W,S}$ is the mass density of saturated water VAPOR at the surface of the evaporation surface (e.g., vapor BUBBLE), and $\rho_{W,\infty}$ is the vapor mass density outside the biological tissue (i.e., cell). Because of the fact that evaporation inside the cell with the CELL MEMBRANE intact changes the internal pressure (sometime reaching several hundred ATMOSPHERE), thus affecting the thermodynamic parameters in the process as a dynamic system. The local metabolic heat generation can generally be neglected. Integration of the heat equation over a volume of tissue yields $V \rho c_V \partial T / \partial t = \iint_s k_T \nabla^2 T * \vec{n} \cdot d\vec{s} - V \omega_b \rho_b c_b \rho (T - T_b) + qV - Q_W - Q_{\text{coag}}$ where the volume of heated tissue has a surface area s , $\vec{n}$ is the normal to the surface of the area over which heat is radiated out, and Q_W and Q_{coag} are the rate of heat loss due to coagulation as well as evaporation (i.e., dehydration), respectively. Because of the DYNAMICS of the local light distribution and the changing thermodynamic parameter, the heat equation generally requires solving numerically by stepwise integration over time to produce the temperature distribution within the full length of the duration of laser irradiation. The tissue is therefore divided into volumetric units that are homogeneous and in steady state during the integration step duration. These volume ELEMENTS are called voxels. The VOXEL dimensions close to the laser impact will need to be smaller than that at large diffusion DISTANCE. This is referred to as a finite ELEMENT method in mathematical procedures. In the tissue, the volume element, voxel v_{ijk} , will yield a finite time description for the temperature, assuming in first-order noncompeting processes in three dimensions as $\partial^2 T / \partial x^2 = (T_{i+1} - T_i + T_{i-1}) / [(i+1) - i(i-(i-1))]$; $\partial^2 T / \partial y^2 = (T_{i+j1} - T_j + T_{j-1}) / [(j+1) - j(j-(j-1))]$; and $\partial^2 T / \partial z^2 = (T_{k+1} - T_k + T_{k-1}) / [(k+1) - k(k-(k-1))]$. Stepping through the NUMERICAL process will provide the change in temperature due to energy deposition by laser irradiation in tissue while accounting for all inherent losses. The next stage in the determination of thermal damage is the calculation of the degree of tissue degeneration as a function of local temperature MAGNITUDE and exposure time.

photocoagulation: coagulation can be reversible or irreversible. Whether a process is reversible or not depends on the total amount of energy delivered and the time frame over which the total amount of energy is administered. In general, chemical reaction takes place in infinitesimally small temporal steps and the ensuing changes in chemical composition take place gradually and can be considered reversible. In a reversible process, the system is always at equilibrium, and will revert to the starting conditions when no additional energy deposited, subsequently releasing the energy that was initially deposited. REVERSIBLE

PHOTOCOAGULATION: in a **REVERSIBLE PHOTOCOAGULATION** process the changes to the molecular bond configuration can revert back to the original state without resulting in a change in entropy. Histological examination may under these conditions reveal changes that are not classified as denaturation. Reversible damage constitutes cell membranes that are still intact and a surviving nucleus. Under normal conditions the reversibly damaged region will be equivalent to normal healthy tissue after a healing period. Typical proteins have an energy range in which they are stable. For instance, the range of stability between folded and unfolded protein strands is resilient from 7 to 15 kcal/mol of added heat at 37°C. This stability energy level is defined as the (Gibbs) free energy of the protein. **IRREVERSIBLE PHOTOCOAGULATION:** the process of **IRREVERSIBLE PHOTOCOAGULATION** is defined by either or both the destruction of the cell membrane and/or nucleus. Including the **SECOND LAW OF THERMODYNAMICS** it will follow that for an irreversible process in an **ISOLATED SYSTEM** the entropy will by definition increase: $\Delta S = S_{\text{final}} - S_{\text{initial}} > 0$. The molecular disorder associated with the increase in **ENTROPY** (S) has been defined by **LUDWIG EDUARD BOLTZMANN** (1844–1906) as the natural log of the number of all possible configurations within a system ω , multiplied by the Boltzmann constant: $S = k \ln \omega$. An equilibrium condition corresponds to $\partial S = 0$, where S represents the maximum attainable entropy. In order to describe the process of photocoagulation providing irreversible damage, the internal energy of the molecules that constitute the tissue needs to be considered. The change in internal energy of a system exposed to external influences is defined as the change in enthalpy for the molecular system $\Delta H = U + \Delta(PV)$, incorporating the work done by changing volume and/or pressure $\Delta(PV)$, which, under constant pressure, becomes the volume labor: $P\Delta V$. Incorporating the **IDEAL GAS LAW** ($PV = nRT$), this transforms to a chemical reaction: $\Delta H = U + \Delta nRT$, where Δn equals the change in molecules resulting from the (thermally induced) chemical reaction, and $R = 8.3144621 \text{ J/mol K}$ is the universal gas constant. The temperature of the system (T) is measured in kelvin. The enthalpy change in an **EXOTHERMIC REACTION** of a system is considered to be negative, which entails that the chemical reaction produces heat. **PHOTOCOAGULATION** will constitute an endothermic reaction, where heat is absorbed, rendering the change in enthalpy for the system positive. The change in free energy of the system (Gibb's free energy: G) combining the enthalpy and entropy and yields $\Delta G = \Delta U - T\Delta S - S\Delta T + \Delta nRT + nR\Delta T$. Building on this the chemical process of denaturation is described as follows: $\Delta G_{\text{den}} = \Delta H_{\text{den}} - T\Delta S_{\text{den}}$, which applying the chemical process $aA + bB = cC + dD$ $\Delta G = xJ$ yields $\Delta G_{\text{den}} = \Delta G_{\text{native}} + RT \ln \left[\frac{[C]^c [D]^d}{[A]^a [B]^b} \right]$, where $[A]$ and $[B]$ represent the respective native molecular concentrations, and $[C]$ and $[D]$ are the concentrations of the denatured states for the molecules involved in the respective processes. Using the fact that the entropy change ΔS_{den} will be positive, it can be shown that $\Delta S_{\text{den}} = k \ln \left(\omega_{\text{denatured}} / \omega_{\text{native}} \right)$, where ω_{native} is the fraction of native (protein) molecules and $\omega_{\text{denatured}}$ the fraction of ensuing denatured molecules resulting from the administered heat. The fact that the entropy change will be positive is the result of the fact that denatured proteins will have more configurations available than the native proteins: $\omega_{\text{denatured}} / \omega_{\text{native}} \gg 1$. In comparison, when the temperature is high enough, the change in free energy will be negative, implying that the denatured state is stable at high temperature and that the native state is stable at low temperature. In the process of photocoagulation, the energy deposited by the laser light is the activation energy used by the denaturation process. An example of the reaction process with hypothetical energy levels. The standard Gibbs energy difference between the transition state from **GROUND STATE** to product for the reactants is calculated from the experimental rate constant k_r based on the conventional form of the Eyring absolute rate equation. The **EYRING ABSOLUTE RATE EQUATION** relies on the fact that the energy for each reaction is subject to **QUANTUM THEORY** due to the discrete nature of the chemical reactions: $\Delta G = RT \left[\ln(k/h) - \ln(k_r/T) \right]$, where k is the Boltzmann constant and h the **PLANCK CONSTANT** ($k/h = 2.08358 \times 10^{10} \text{ K}^{-1} \text{ s}^{-1}$). The values of the rate constants, and hence Gibbs energies of activation, will depend on the choice of concentration units, and the choice of thermodynamic ground state of the chemical medium. The standard enthalpy of activation for the process is $\Delta^\ddagger H^0$, which represents the enthalpy change in the rate equation obtained from conventional transition state theory. Alternatively, the quantity $\Delta^\ddagger S^0$ represents the standard entropy of activation. Solving the chemical process for change in molecular quantity, Δn yields an expression for the **PROBABILITY** of conversion between the native protein state and the denatured state k_r , defined as $k_r = (kT/h) e^{\Delta^\ddagger S^0/R} e^{-\Delta^\ddagger H^0/(RT)}$, also written as $k_r = A' e^{-E^*/(RT)}$.

The empirical reaction constants A' and E^* can be defined based on the fact that the rate of change for the transition from the native protein state to the denatured state takes place at kT/b ; this provides $A' = (kT/b)e^{\Delta S/R}$ and $E^* = \Delta H$. Generally, these constants are experimentally determined since there is not merely a single MOLECULE involved in the denaturation process for a biological specimen. The denaturation process is verified either by functional analysis (in situ) or by identified of histological markers of nuclear destruction. DAMAGE INTEGRAL: the numerical expression for achieving irreversible tissue damage can be derived from the so-called damage integral. The damage integral calculates the loss of normal tissue based on a standard reaction equation, transforming into the denatured state:

$\Omega(t) = \ln[N_{\text{total}}] / ([N_{\text{total}}] - [N_{\text{denatured}}]) = A' \int_0^t \exp(-E^*/RT) dt$, where $[N_{\text{total}}]$ defines the total number of cells in the tissue volume that is subject to irradiated by light and $[N_{\text{denatured}}]$ the number of denatured cells post laser irradiation. On a more complex scale, this is defined as follows. When there are initially N_0 molecules of one molecular species in a volume of tissue, the number of surviving molecules is proportional to the native number, and the rate of denaturation dN obeys the heuristic equation $dN = k_r N dt$. The number of surviving native molecules as part of the denaturation process as a function of time is defined as $N(t) = N_0 e^{-\Omega(t)}$, where $\Omega(t) = \int_0^t k_r(t') dt' = \int_0^t [kT(t)/b] e^{\Delta S/R} e^{-\Delta H/(RT(t))} dt'$. The expression $\Omega(t)$ is called the damage integral for the coagulation process. At any time during the photocoagulation process, the number of denatured molecules, $N_{\text{denatured}}(t)$, equals $N_0 - N(t)$. Thus, the damage integral incorporates the average values of all molecules involved in the denaturation process but specified by tissue section. The rate value k_r depends on the temperature of exposure and the values of ΔS and ΔH , which are characteristic for most measurable transitions in the chemical processes for the respective tissue. Examples of chemical transitions are the coagulation of egg white (cooking an egg, which may be performed by MICROWAVE ELECTROMAGNETIC RADIATION), the irreversible loss of enzymatic ACTIVITY that involves denaturation of labile proteins, and the whitening of soft tissues such as MUSCLE or LIVER during cooking (grilling out, frying pan, or using electromagnetic radiation: INFRARED lamps, laser, microwave). Each of these processes involves denaturation as well as the AGGREGATION process for proteins. The coagulation of collagenous tissue will yield gelatin, which involves the loss of collagen fiber bundle structure, such as that used for wrinkle removal. The rate constant k_r at a given temperature will have a value that is specific for different transitions. For example, second-degree burns can be captured by a value $\Omega > 10$, and for third-degree burns the value $\Omega > 10000$ is generally accepted. The more complex the molecular structure that is involved in the denaturation process, the steeper the change in rate constant with temperature. This change is due to the fact that the change in entropy (ΔS) is greater in addition to the fact that the number of bonds are being broken concurrently at a larger number (ΔH). The rate constant k_r for each tissue will vary as a function of temperature. In the denaturation process, generally the exposure time (t_Ω [s]) required to achieve $\Omega = 1$ is one of the parameters of interest. This exposure time is by definition $k_r = 1/t_\Omega$. When denaturing a less structured tissue, the chemical matrix will DECAY more gradually, with an associated change in rate constant due to the less vigilant changes in ΔS and ΔH in response to the temperature changes. The molecular structure involved in an irreversible thermal transition (denaturation) has in first-order approximation an entropy ΔS release linearly related to the enthalpy change ΔH for that particular transition. The enthalpy change ΔH describes an independent variable that is conceptually integral to the energy of all bonds that cooperatively provide the cohesive force for a molecular structure. The increase in entropy is generally considered to be a dependent variable, associated with the bond-breaking energy change. Examples of published average empirical values for tissues are skin $E^* = 627 \text{ kJ mol}^{-1}$, $A' = 3.10 \times 10^{98} \text{ s}^{-1}$; and collagen $E^* = 89 \text{ kJ mol}^{-1}$, $A' = e^{130} \text{ s}^{-1}$. The DAMAGE STATE: the damage region $0 \leq \Omega(t) \leq 0.53$ is generally considered to be reversible, or rather will not cause any (permanent) damage whatsoever to the tissue. The damage range $0.53 < \Omega(t) < 5$ will provide tissue coagulation. Generally, $\Omega(t) < 1$ can be used to define reversible tissue damage. A value of $\Omega(t) = 4.6$ represents the condition providing 99% probability of tissue denaturation. At $\Omega(t) > 5$, the tissue is susceptible to carbonization. Based on this, the following timelines can be projected for exposure to extreme solar energy (desert conditions): a second-degree burn resulting from skin

exposure to 135°C yields a time exposure of approximately 2.5 min, while a third-degree burn can be expected after exposure lasting in excess of on the order of 1 day and 18 h. The time–temperature correlation associated with final irreversible damage is one critical factor in the assessment process with respect to the thermal damage (see Figure P.66).

Figure P.66 (a) Port-wine stain removal. (b) Photocoagulation process for port-wine stain computational model.

Photocopy

[general] Process that transfers a charge density image of a real paper image over on role that is coated with ink, with ink density proportional to charge density, from which the ink is transferred to paper in a printing process: rolled over the paper (Xerox process). The charge distribution is achieved through a corona process, which generates an intense flash of LIGHT that ionizes the photographic role or alternatively the paper directly. Alternatively, the paper itself is ionized and the ink (toner) is directly transferred to the paper (electrostatic process). The charge density is the result of an ionic transfer process based on a flash discharge (corona) in the early devices. The process is used to generate a gray-scale/black and white copy of an illustration or object. The photocopy process has evolved to the use of laser scanners to scan original paper or object that is targeted for image formation on paper. The transfer of ink to regular paper has an efficiency of better than 90%. Dry paper can hold a charge distribution for several seconds, allowing the charged toner (ink) to adhere in a proportional fashion. The fusing process following the deposition will make the IMAGE permanent. Fusing can be accomplished by pressure, which is generally achieved by running the paper between two hot rollers. The FUSION process with the paper takes place at around 130°C . Thermal fixation with radiant heat alone is not very efficient due to the reflectivity of most paper materials. In a more elaborate process, the use of a spray-on fixative (e.g., EVAPORATION) is applied prior to the pressure roller process. The same process is used to transfer an image into a two-dimensional digital array for FAX transmission. The machine that performs the process is called a photocopier. Photocopy MACHINES are also known as Xerox machine, based on the success of the largest manufacturer, and patent holder, in the early glory days. The dry photocopy process was first introduced in 1938 by the physicist Chester Carlson (1906–1968), working for the Haloid Photographic Corporation, renamed to the Xerox Corporation in 1961. The dry process stands in contrast to wet printing used in the early days of newspaper printing where an etched plate is wetted with ink that is transferred to paper. The etched plate is mounted on a roller, which allows multiple prints with the identical image to be generated without the need for elaborate technology. The earliest form of physical paper printing from a

carved plate (wood plate to be exact) is documented to have been performed in China around the year 200. The automated printing press dates to 1453 (*also see* LITHOGRAPHY) (see [Figure P.67](#)).

Figure P.67 Photocopy process: (1) Charging—the surface of the photoconductor is uniformly charged by the charging device; (2) Exposure—the document to be copied is illuminated and its image projected onto the photoconductor to form a latent image; (3) Development—the charged toner particles are attracted to the latent image, forming a visible image on the photoconductor; (4) Transfer—the toner image is transferred to the paper. In other step, the toner image is permanently fused to the paper; (5) Cleaning—Any remaining toner is removed from the photoconductor surface; (6) Erasing—the photoconductor surface is exposed to light to remove any remaining electrostatic charge. (Courtesy of Fuji Xerox.)

Photocurrent

[general] Electron current resulting from interaction of ELECTROMAGNETIC RADIATION with a material. The material can be artificial or natural. Examples are zinc as a natural material or silicone and germanium as a man-made medium (*see* PHOTOELECTRIC EFFECT).

Photodetector

[electronics, optics] Device that converts ELECTROMAGNETIC RADIATION into electrical current by either releasing valence electrons (i.e., PHOTOCURRENT) or by generating an electrical potential (electromotive force) that will generate a flow of electrons when a circuit is completed. Examples of photodetectors are photoconductors, junction photodetectors, and avalanche photodetectors. Photoconductors will change resistance under the influence of electromagnetic RADIATION, moving additional electrons to the VALENCE BAND. Junction photodetectors are for instance the SCHOTTKY DIODE, respectively layered Positive-Intrinsic-Negative doped (PIN) diodes, and Metal-Semiconductor-Metal (MSM) stacked diode. Avalanche photodetectors operate based on

ionization efficiency, more specifically the difference in ionization between two materials. The IONIZATION process is the result of the quantum-well mechanism (see [Figure P.68](#)).

Figure P.68 Microchip light sensor.

Photodisintegration

[atomic, nuclear] High-energy electromagnetic interaction on a NUCLEON level. The interaction cross-section can be described using Lorentz invariance as $\int_0^\infty [\sigma^p(k) - \sigma^A(k)] dk/k = 2\pi^2 \alpha S_i [K_i/m_i]^2$, where $\sigma^p(k)$ is the inelastic photon CROSS SECTION for polarized LIGHT parallel interacting with the target spin (S_i), $\sigma^A(k)$ is the inelastic PHOTON CROSS SECTION for polarized light on antiparallel interacting with the target spin, K_i the anomalous MAGNETIC moment of the target, m_i the target mass, $k = 2\pi/\lambda$ the wave-number, λ the wavelength, and α a condition constant. One specific interaction is described for the photo-disintegration of a DEUTERON.

Photodynamic therapy (PDT)

[biomedical, chemical, energy, optics] The use of LIGHT to affect biological properties. The use of light to treat medical conditions and general SKIN disorders has been documented as far back as approximately 1550 BC in the Ebers papyrus to treat pigmentation disorders assumed to be associated with leprosy. The PDT applications for clinical use on smallpox was described by the physician HENRI DE MONDEVILLE (1260–1320). More in-depth work on photodynamics interaction was described by OSCAR RAAB (1876–1986) and his work under the guidance of Hermann von Tappeiner (1847–1927) based on the PHOTOTOXICITY by Marcacci in 1888. In cancer treatment, photodynamic therapy uses a chemical mediator

that produces unstable and aggressive singlet oxygen, which rapidly oxidizes cells and effectively kills the cell. The efficacy of the photodynamic therapy is dependent on the wavelength of the light used with respect to the activation biochemical as well as the tissues the light is required to pass through to reach the target locations below the surface of the biological medium. The photosensitizer must adhere to several criteria to ensure efficiency: selective uptake in the tumor, activation by specific wavelengths that will penetrate deep into the tissue. The photochemical cannot be toxic by itself, and it has to have the capability to destroy malignant tissue growths once activated. The effectiveness of the photosensitizer depends largely on the localization of the drug in the tumor, and the light transmittance of the tissue that surrounds the tumor, at the activation wavelength. The PDT treatment is hence a function of the SOLUTION to the EQUATION OF RADIATIVE TRANSFER, as well as the conversion efficiency on a chemical level. One particularly important clinical application of PDT is in brain tumor. Generally, the spear and uptake of the photosensitive dyes (i.e., photoporphyrins) are not selective and will easily be distributed wherever BLOOD flow is available, thus using the local perfusion as an indication of the local photoporphyrin concentration. Certain photoporphyrins are designed to selectively bind to brain tumors, taking advantage of certain modifications in the blood–brain BARRIER due the tumor presence. Under normal/healthy conditions the photochemical will not be allowed to pass the blood–brain barrier based on the PHYSIOLOGY of this particular part of the CIRCULATION (see [Figure P.69](#)).

Figure P.69 Photodynamic laser therapy for cancer treatment using deep penetrating light and photoactivated chemicals that are concentrated in the cancer tissue volume.

Photoelasticity

[optics, mechanics] A material property with respect to the optical characteristics of an anisotropic medium wherein incoming single beam of unpolarized LIGHT enters into an medium where at the interface it is split into two rays traveling in different directions. The primary ray (called the ordinary ray) will be transmitted through the medium unchanged. A second ray is also formed in the BIREFRINGENCE process called the extraordinary ray, which is refracted at an ANGLE and will emerge at a different angle and location from the

opposite side of the medium. Examples of materials that are naturally birefringent are calcite crystal, frozen water (ice), sapphire, QUARTZ, and a wide selection of PLASTICS. Under the concept of *photoelasticity* optically transparent materials that are ordinarily not double refracting (birefringent) can be made to be birefringent under influence of applied stress. Examples of such materials are certain types of GLASS (BK7), CELLOPHANE, lucite and BAKELITE. The optical change, specifically the mechanically induced photoelasticity, can be used for quality control issues, highlighting location-specific discontinuities in the transparent patterns, specifically the spectral distribution, and potentially the changes in POLARIZATION angle of the transmitted light. These discontinuities will be cause for rejection or will require additional investigation for mechanical consistency. In this field, the following terms are used to define the optical characteristics of the medium: linear birefringence, circular birefringence, uniaxial, biaxial, and chiral birefringence. A special form of birefringence is Brillouin SCATTERING in birefringent media. Additionally, gyrotropic media become isotropic media under the influence of an external constant MAGNETIC FIELD. Examples are Earth's IONOSPHERE (furthermore, various plasma conditions), semiconductor materials, ferrites, and specialty fiber-optics. Additionally, the POCKELS EFFECT (after the German physicist FRIEDRICH CARL ALWIN POCKELS [1865–1913]), who in 1893 discovered that a steady electric field or a varying electric field applied to certain materials will induce birefringence by causing the refractive index to vary (*also see* KERR EFFECT). The practical application of the Pockels effect is applied to Pockels cells providing the mechanism of operation for Q-switched lasers (*also see* BIREFRINGENCE) (see Figure P.70).

Figure P.70 Photoelasticity.

Photoelectric cells

[atomic, nuclear] Device for which the electrical characteristics are a function of incident LIGHT, providing electromotive force. Specifically, the conversion of ELECTROMAGNETIC RADIATION into electric ENERGY, producing a voltage (V_{EMF}) as a function of radiance. The mechanism of action depends on the PHOTOELECTRIC EFFECT. Additionally, the electrical RESISTANCE may change linearly with the incident radiance, hence providing a mechanism of measuring the MAGNITUDE when connected to a voltage source and a GALVANOMETER (VOLTMETER). As was described in 1897 by JOSEPH JOHN THOMSON (1856–1940), who showed that the

increased electrical sensitivity of material was caused by “light pushing on electrons” (also referred to as PHOTOCELL) (see [Figure P.71](#)).

Figure P.71 Photocell, semiconductor device relying on photoelectric effect (i.e., photovoltaic effect) to generate electricity, c.q. electrical potential.

Photoelectric effect

[biomedical, energy, nuclear, optics] The conversion of ELECTROMAGNETIC RADIATION ENERGY into kinetic energy of a loosely bound electron (i.e., VALENCE electron) culminating in the emission of a free electron from the ATOM providing the opportunity to initiate the flow of electrons and hence produce current. The PHOTON ENERGY will need to exceed the WORK FUNCTION (ϕ_{elec} , in electron volt eV) of the material in question. The relationship between the work function of the material/metal exposed to LIGHT (with energy $h\nu$, where $\nu = c/\lambda$ is the frequency of electromagnetic radiation with wavelength λ traveling at the speed of light: c and $h = 4.13567 \times 10^{-15} \text{ eV} = 4.1356692 \times 10^{-15} \text{ Js}$ is PLANCK'S CONSTANT) and the electron energy (KE_e) is expressed as $h\nu = \text{KE}_e + \phi_{\text{elec}}|_{\text{Metal}}$. Hence the threshold for the photoelectric effect is provided by $\nu_0 \geq \phi_{\text{elec}}/h$. The PROBABILITY of photon-electron interaction increases with: $h\nu \xrightarrow{\text{approaches}} E_B$, or: $\nu \xrightarrow{\text{approaches}} \nu_0$, where $\nu_0 = E_B/h$ is the frequency of the ABSORPTION EDGE resulting from resonant interaction with the orbiting electron, revolving with NATURAL FREQUENCY: ν_0 at BINDING ENERGY E_B . Under certain specific conditions the simultaneous capture of more than one photon, each at below threshold energy levels, can still result in a multiphoton photoelectric effect. The cumulative energy of multiple photons will exceed the threshold conditions. This is primarily reserved for ultra-short pulsed LASER irradiation, with inherently high RADIATIVE EMISSION per pulse (RADIANCE in order of MW per pulse) (see [Figure P.72](#)).

Figure P.72 Work performed at the University of North Carolina at Chapel Hill in biological photovoltaics. (a) Schematic showing a modular approach to a process termed artificial photosynthesis. The “artificial photosynthesis relies on similar principles as used by plants, absorbing sunlight and using those photons to split water that provides the protons and high-energy electrons needed to reduce CO_2 to make plant parts (carbohydrates). Modifying the photovoltaic mechanism of action of nature with dye-sensitized solar cell technology to make a dye-sensitized photoelectrosynthesis cell (DSPEC) is shown in schematic form. PEM stands for proton exchange membrane, C stands for chromophore (a.k.a. light absorber), D stands for donor, Cat_{ox} stands for catalyst designed for oxidation (e.g., water oxidation catalyst), Cat_{red} stands for catalyst designed for reduction (e.g., CO_2 reduction catalyst), CB stands for conduction band, and VB stands for valence band. Strictly speaking, D is not a requirement, just might help the device to separate redox equivalents at the two catalysts. (b) Schematic showing a new approach to photovoltaics by incorporating a light-harvesting antenna capable of very rapid energy transfer down to the surface of the electrode. The nanostructured photonic electrode also serves to trap light for higher efficiency, capturing much light as in comparison to the structure and working function of a butterfly’s wing. (Courtesy of Kyle Brennaman, University of North Carolina Chapel Hill; Chapel Hill, NC.)

Photoelectric equation

[general] Definition of the kinetic ENERGY (E_k) of an electron emitted from a METAL as a result of the absorption of a radiation QUANTUM as a function of the electromagnetic FREQUENCY (ν): $E_k = h\nu - \omega_w$, where $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ is PLANCK’S CONSTANT, and ω_w the work function of the metal, as introduced by ALBERT EINSTEIN (1879–1955) in 1905. The PHOTOELECTRIC EFFECT was first observed by HEINRICH HERTZ (1857–1894) in 1887 during his experimental work on RADIO receivers with a spark-gap GENERATOR.

Photoelectric nuclear effect

[nuclear] In nuclear PHYSICS, it can be annihilated by means of gamma radiation. The condition is that the photon ENERGY $E_{\text{photon}} = h\nu$ needs to exceed the BINDING ENERGY of the PARTICLE involved. One specific example is the disintegration of DEUTERON, ${}_2^1\text{D} + h\nu \rightarrow {}_1^1\text{H} + {}_0^1\text{n}$, producing hydrogen and a NEUTRON. Additionally, this phenomenon has been recreated for beryllium. An additional phenomenon describes the pair production under the passage of a GAMMA RAY close to the NUCLEUS; a PHOTON with energy $E_{\text{photon}} = h\nu > 1.022\text{ MeV}$ can produce two “electron particles:” electron and positron, each traveling in perfectly opposite direction, with respective energy $E_{\text{positron}} = 511\text{ keV}$, which is the mechanism of action for pair production in POSITRON EMISSION TOMOGRAPHY (PET).

Photoelectron

[general] Electron released from METAL under influence of ELECTROMAGNETIC RADIATION (see PHOTOELECTRIC EFFECT).

Photographic plate

[chemical, general, optics] Surface coated with a light-sensitive emulsion that changes its transparency or REFLECTION after exposure to LIGHT, primarily resulting from oxidation, for example, silver chloride, which is converted to. The principle of chemical photographic (i.e., light-sensitive oxidation) sensitivity was discovered by the chemist (alchemist) Georg Fabricius in 1556; that is, LUDOLF GEORG GOLDSCHMIED, Prussian-German chemist (1526–1581) in his publication “De Rebus Metallicis” related to the darkening of “horn silver” [silver chloride] under exposure to light. Another photographic emulsion is silver nitrate with calcium. In 1777, the Swedish scientist and chemist CARL WILHELM SCHEELE (1742–1786) discovered that silver chloride has wavelength-dependent light sensitivity, primarily related to the difference between OXIDATION resulting blue light with respect to the longer wavelengths of the visible light (see [Figure P.73](#)).

(a)

(b)

Figure P.73 (a) Old-style studio camera with objectives and a framework for viewing photographic plate and (b) Georg Fabricius (Goldschmidt: 1526–1581).

Photography

[biomedical, imaging, optics] The process of producing an IMAGE on a plate based on incident ELECTROMAGNETIC RADIATION originating from a set of real objects, respectively transmitted through a real object (e.g., X-RAY radiation). The imaging system can be analog, using silver halide crystals as the image-forming medium (photographic film; CELLULOSE ACETATE film), or digitally based on charge-coupled device technology PIXEL array (digital CAMERA). The word “photographie” was first used by the French scientists Joseph Nicéphore Niépce (1765–1833) in 1826 and is known for his pioneering efforts in the development of photography with the first photograph displayed in 1825. The great deal of effort was contributed by the scientist and inventor from the United States, GEORGE EASTMAN (1854–1932) commercialized by the Eastman-Kodak corporation, known as Kodak (see Figure P.74).

Figure P.74 The art of photography exemplified by a high-speed frame capture (“freeze-frame”) of tea being spilled from a cup.

Photomultiplier tube

[atomic, nuclear] VACUUM tube that uses a cascade system to increase the number of electrons released from the incident PHOTON by means of the PHOTOELECTRIC EFFECT. Several plates positioned in a sequence are under a potential difference, which accelerates the initial PHOTOELECTRON to the second plate where additional electrons are released by collision impact. $E_k = h\nu - \omega_m$, where $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ is PLANCK’S CONSTANT and ω_m the work function of the METAL (specific for photon interaction), as introduced by ALBERT EINSTEIN (1879–1955) in 1905, which is primarily a function of the electromagnetic FREQUENCY (ν) of the incident RADIATION. The number of secondary electrons released by the collision is a direct function of the electron kinetic ENERGY, which depends on the electrical potential between the plates: $E_k = k_e \left(\frac{e^2}{r} \right) - \omega_{m,c}$, where $k_e = 1/4\pi\epsilon_0$ is the Coulomb constant with $\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{Nm}^2$ the permittivity of free space, $e = -1.60217657 \times 10^{-19} \text{ C}$ is the electron charge, r is the separation between the subsequent plates in the photomultiplier (dynodes), and $\omega_{m,c}$ is the release energy of the metal under collision. Generally, a single photoelectron can generate up to 10^7 secondary electrons, finally detected on the terminal ANODE, which are quantified by a GALVANOMETER (VOLTMETER). PHOTOMULTIPLIER TUBES have an inherent high internal gain and are extremely sensitive detectors for low-radiance detection applications;

however, they are relatively large and require an elaborate power supply, operating at a high negative voltage, typically ranging from -500 to -1500 V (see [Figure P.75](#)).

Figure P.75 Photomultiplier tubes inside a drum scanner.

Photon

[atomic, general, optics, quantum] Quantity of ENERGY emitted in the form of ELECTROMAGNETIC RADIATION with a value that is the product of its FREQUENCY (ν) and PLANCK'S CONSTANT ($h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$): $E = h\nu$ (quantum of LIGHT), this has a continuous distribution spectrum. The photon is the result of a charge OSCILLATION, where the ELECTRIC CHARGE (q) carries an electric field (E_{elec}), while the MOTION of the charge generates an alternating current (I , with the same frequency as the oscillation; FARADAY LAW): $I = I_0 \sin \omega t = dq(\vec{r})/dt$, where $\omega = \nu 2\pi$ is a function of charge location $\vec{r}$, which is the essential component to induce an associated and frequency matching alternating MAGNETIC FIELD ($\vec{B}$) (AMPÈRE'S LAW: $\oint \vec{B} \cdot d\vec{\ell} = \mu_0 I$, where the integral is taken over a loop around the current, and $\mu_0 = 4\pi \times 10^{-7} \text{ H/m}$ the permeability of free space). The energy of the photon is expressed by the Pointing vector. The vector direction of the electric field defines the POLARIZATION of the electromagnetic radiation. Photons are generally described by the WAVE–PARTICLE DUALITY principle. Sometime treating the photon as a PARTICLE provides the essential mechanism for the process, for instance REFLECTION. Whereas the wave phenomenon is more suitable for several other interactions, for instance diffraction and INTERFERENCE. The particle theory dates back to the ancient Greek philosophers (starting as far back as Aristotle [384–322 BC]), but SIR ISAAC NEWTON (1642–1727) formally introduced his corpuscular hypothesis. The first formal

introduction of the wave theory of light was introduced by the Dutch scientist CHRISTIAAN HUYGENS (1629–1695). Photons span the entire ELECTROMAGNETIC SPECTRUM (see Figure P.76).

Figure P.76 The elusive photon.

Photopic vision

[biomedical, optics] Part of the three main modes of human vision: photopic, scotopic, and mesopic. Photopic vision represents VISION under brightly lit conditions. Photopic has COLOR perception, encompassing all functions associated with the cone cells in the retina of the EYE. Scotopic vision is black and white vision (“intensity” [magnitude] only. *Note:* intensity is technically not appropriate for ELECTROMAGNETIC RADIATION due to the duplicity of the nature of LIGHT, intensity is the AMPLITUDE squared) under low-light radiance conditions, attributed to the rod cells in the RETINA. Mesopic vision combines the low-level rod vision and bright cone vision, a combination of photopic vision and scotopic vision (see Figure P.77).

(a)

(b)

Figure P.77 (a) Photopic vision under bright sunlight and white reflecting buildings and (b) in comparison mesopic vision under artificial lighting in a grocery store.

Photosphere

[astrophysics/astronomy, geophysics] Solar layer, consisting of a PLASMA-nuclear reaction medium, primarily responsible for the LIGHT emission, the corona. The photosphere of our SUN is approximately 600 km thick. While brighter and hotter stars will have a thicker photosphere, it is estimated that the thickness is

generally $1/1000$ of the total radius of the solid STAR. The composition of the photosphere s generally inferred from the emitted Fraunhofer spectrum (see [Figure P.78](#)).

Figure P.78 Layers of the Sun, outlining the photosphere.

Photosynthesis

[biomedical, geophysics, thermodynamics] The phenomenon of the conversion of carbon dioxide to oxygen by plants as postulated in 1779 by a scientist from the Netherlands: JAN INGENHOUSZ (1730–1779).

Even though the discovery of the molecule oxygen (O_2) was only recent in these days of discovery in 1774, by JOSEPH PRIESTLEY (1733–1804) (see [Figure P.79](#)).

Figure P.79 Process of photosynthesis, primarily known for its action through the chloroplasts in the leaves of plants; however, the skin of various mammals also has photosynthesis capabilities. The skin photosynthesis also produces a necessary hormone and chemical catalyst for cellular function: vitamin D, in addition to a rudimentary supply of oxygen. During exposure to sunlight, high-energy ultraviolet light (specifically in the range 290–315 nm) is absorbed in melanin that is part of the tissue structure directly underneath the epidermis of the skin and the photon energy is used to photolyze provitamin D3 (7-dehydrocholesterol) to previtamin D3. Once previtamin D3 is formed, it undergoes an isomerization process that is thermally induced and forms vitamin D3. The isomerization process takes 2–3 days to reach completion. Additionally, certain algae and seaweed and certain organisms, such as the *Euglena* species (found in both fresh- and saltwater), also provide a significant contribution to the conversion of carbon dioxide into oxygen. Some scientists claim that algae and seaweed combined provide the lion's share of oxygen production, exceeding that of surface plants. The true respective contributions remain difficult to quantify accurately due to a broad range of ill-defined and transient boundary conditions.

Phototoxicity

[biomedical, chemical, optics] Inflammatory toxic response, primarily associated with the SKIN, under the influence of LIGHT exposure of surface areas that have been in contact with certain chemicals. Phototoxicity may sometimes be misdiagnosed as sunburn but is a different dermal response on a chemical and cellular level.

Photovoltaic effect

[atomic, nuclear] Electric current generated as the result of light irradiance of a junction between two media of different chemical composition in direct contact. The effect was first observed by ANTOINE HENRI BECQUEREL (1852–1908) in 1839. The photovoltaic effect can also be applied in combination with an externally induced potential difference (V), providing a CURRENT (I) as a function of the irradiance (I_{rad}) and temperature at the junction (T): $I = I_{\text{reverse}} \{ \exp(eV/kT) - 1 \} - I_{\text{rad}}$, where $e = 1.60217657 \times 10^{-19} \text{ C}$ is the

electron charge and $k_B = 1.3806488 \times 10^{-23} \text{ m}^2 \text{ kg/s}^2 \text{ K}$ is the BOLTZMANN CONSTANT (*also PHOTOVOLTAICS or PHOTOELECTRIC EFFECT*) (see [Figure P.80](#)).

Figure P.80 Graphic representation of the photovoltaic effect.

Physics

[general] (Ancient Greek: φύσις physis “nature;” the Knowledge of Nature, in principle the knowledge of how things work and how phenomena originate. Latin: physica, plural, “natural science”) A natural science that involves the study of MATTER, phenomena, the MOTION of object and phenomena through both space and time, as well as all related force and ENERGY concepts. More broadly, the general hypothetical description and analysis of nature, with associated laws of conservation and rules and laws of conduct. The study of physics postulates rules about the conduct of events and phenomena in order to understand, and predict how the UNIVERSE behaves and how matter and energy interact. Most laws and definitions in physics are proven within certain boundary conditions and are correct until new observations require adjustments to the theory, one example is the special relativity concepts, following classical Newtonian physics. The first known use of the “physics concept” was 1715. The broad spectrum of physics has been further subdivided into the following topics: classical, high energy, nuclear, relativistic, THERMODYNAMICS, FLUID DYNAMICS, hydrodynamics, fluid mechanics, dynamics, statics, MECHANICS, OPTICS, photonics, QUANTUM MECHANICS, electromagnetism, BIOPHYSICS, theoretical physics, GEOPHYSICS, ASTROPHYSICS, ACOUSTICS, high-pressure, low-temperature, PLASMA physics, particle physics, and many new subdisciplines being demarcated on a continual basis. The list of areas of interest in physics is not intended to be all encompassing, various topics

will overlap between the nomenclature and also depend on the respective execution-group interests (see Figure P.81).

Figure P.81 Physics as a technology platform.

Physics constants

[general] Broad range of constants used in the various definitions within the integral field of PHYSICS, ranging from the electron charge to the speed of LIGHT, found in many description throughout the encyclopedia.

Physics laws

See LAWS OF PHYSICS.

Physiologic dead space

[biomedical, fluid dynamics] Physiologic dead space is defined as the volume of expired AIR per breath that does not receive any CO₂ from the BLOOD flow through that part of the lung. In RESPIRATION, the volume capacity of the lung is measured using this as one of the characteristics for the individual examined.

Physiologic dead space quantifies the volume of the trachea, bronchi, and bronchioles, which is not involved in the exchange of oxygen with blood (i.e., anatomic dead space), in addition to the volume of “damaged” alveoli that have vascular constraints that limit the blood flow and hence limit the exchange of oxygen with blood (i.e., alveolar dead space). The method specifically determines the physiological dead space of the lung total expired volume. In certain regions of the lung, there can be a very high ventilation-to-perfusion ratio, with an associated wasted VENTILATION, which acts as physiologic dead space.

Physiologic dead space can be measured using the Bohr method. The Bohr method collects all expired air is over several breaths. The expired partial pressure for those breaths (P_{ECO_2}) is measured. Concurrently, a sample of alveolar air (i.e., end-tidal air; with volume V_t) is collected, the air that is exiting at the end of expiration during forced expiration. This end-tidal air does not contain a significant amount of dead space air, hence serves as a representative of alveolar air. From the end-tidal breath, the alveolar P_{ACO_2} is measured. The total expired CO₂ per breath is by definition from the expired alveolar air. Dead space volume (V_d) can be

derived from the fact that the total amount is concentration multiplied by volume:

$V_a/V_t = (P_{aCO_2} - P_{CO_2})/P_{aCO_2}$ (Bohr equation; defined by the Danish physician CHRISTIAN BOHR [1855–1911]) (see Figure P.82).

Figure P.82 Physiologic dead space in the process of respiration. (a) Normal respiration and (b) volume diagram for the lungs.

Physiology

[biomedical, chemical, general] Study of the activities involved in biological entities. Description and QUANTIFICATION of the operational functionality of organs, cells as well as on a molecular level, including enzyme interactions and hormones. A general study of how biological organism function, with associated ENERGY, balances and ENGINEERING interactions. The first recorded principles of physiology date back to

HIPPOCRATES (approximately 470–377 BC) in 420 BC, hence known as the father of modern MEDICINE (see Figure P.83).

Figure P.83 Brain regulating the activities of a person that is performing an activity and hence has cells that perform a physiological activity.

Physisorption

[atomic, biomedical, energy, thermodynamics] The process of electron interaction on a Van der Waals attraction level, describing the ADSORPTION while the electron structure remains unaffected. The adsorption process refers to the chemical hybridization of electrons in a molecular surface. The electrons in orbit can be considered electron clouds. In contrast during chemisorption the electrons are affected, performing a perturbation of the chemical bonds. Under helium beam interaction with helium the SCATTERING process is described as physisorption with very low ENERGY content (order of meV).

Piano

[acoustics, computational] Acoustical string instrument used to produce music by tapping strings with blocks attached to the keys on the front of the instrument. There are two particular kinds of pianos: upright and grand-piano. The grand piano has gained popularity from the manufacturer Steinway for over 160 years. The history of the piano dates back to the harpsichord of the beginning of the eighteenth century, evolving to the pianoforte. The Harpsichord was invented by the Italian musician and craftsman Bartolomeo Cristoforo (1655–1731). This was the equivalent of what is now known as the “grand piano.” The composer Beethoven was writing music for the piano when the instrument was close to one hundred years old. The upright piano was designed in 1780 by the Austrian Johann Schmidt (late eighteenth century). The “hammer” design of the piano creates a SOUND by actuating the string in a time segment of milliseconds, the duration will largely depend on the force with which the key stroke is played. The key stroke affects the harmonic spectrum of the string as well as the LOUDNESS. The tone spectrum of the piano generally covers better than six octaves, ranging approximately from 25.5 to 4186 Hz for the fundamental frequencies with harmonics spanning from 2 to 12 kHz. The sound spectrum is influenced by the string

material, the string tension as well as the reverberations in the mechanical device housing the strings, with its inherent material properties and stresses and strains (see [Figure P.84](#)).

Figure P.84 Grand piano.

Picard, Jean-Félix (1620–1682)

[astronomy] French astronomer. He equipped a TELESCOPE with Vernier-type gauge lines that could be used for MEASUREMENT and laid the foundation for angular division of the globe in longitude and latitude scales for cartography.

Pickering, Edward Charles (1846–1919)

[astrophysics/astronomy, atomic] Physicist and astronomer from the United States. He is best known for his derivation of the spectral line series: PICKERING SERIES (see [Figure P.85](#)).

Figure P.85 Edward Charles Pickering (1846–1919) by Sarah Goolll Putnam (1851–1912). (Courtesy of Harvard University Portrait Collection.)

Pickering series

[atomic, nuclear] Helium absorption lines for helium found in hot stars. The Pickering lines are for a special IONIZATION state of helium (He^+ , singly ionized, instead of He^{2+}) involving a transition to the $n = 4$ QUANTUM STATE. The Pickering lines closely resemble the transition lines for the BALMER SERIES to the $n = 2$ quantum state.

Pickup reaction

[nuclear] The reverse of a single NUCLEON transfer reaction, in this case a nucleon is removed from the target NUCLEUS.

Picture

[general] Two-dimensional IMAGE captured on a canvas (painting), paper (drawing), digital array, or on PHOTOGRAPHIC PLATE (photographic film), representing a visual PERCEPTION of an object or event. Photographic film, or digital array (digital CAMERA) is the prominent mechanism for capturing a picture and preserving the experience for posterity. In digital image capture, the picture ELEMENTS are referred to as pixels, the individual array elements with the gray-scale respectively COLOR coding information of one location in the total reconstituted display (see [Figure P.86](#)).

Figure P.86 (a,b) Picture of baby “praying mantis” (“walking stick,” since it resembles a tiny branch), insect: *Carausius morosus* of the order Phasmatodea. The population consists virtually exclusively of females. The females are able to lay fertile eggs, without the requirement of mating or for that matter the presence of males. The eggs hatch and also develop into females.

Piezoelectric effect

[acoustics, atomic, energy, fluid dynamics, general, mechanics, quantum] Electromechanical process (i.e., strain) in certain materials. The materials that can produce this effect have specific symmetry features, LATTICE structure related for instance. Additional effects producing the piezoelectric effect include the stress induced in a material by an applied electric field. The piezoelectric effect was discovered in 1880 by PAUL-JACQUES CURIE (1856–1941) and PIERRE CURIE (1859–1906). Example materials that possess the piezoelectric effect are quartz, ferroelectric ceramics, and certain salts. Rochelle SALT (potassium sodium tartrate: $\text{KNaC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$ first known preparation in the late 1600s by Pierre Seignette (1660–1719), an apothecary of La Rochelle, France; used as a laxative); discovered to have pyroelectric properties by SIR DAVID BREWSTER (1781–1868) in 1824 later to show piezoelectric properties by the Curie brothers.

One specific example of the practical use of the piezoelectric effect is in a quartz-based timing mechanism used in clocks, a battery-operated quartz resonator (*also see* ULTRASOUND) (see [Figure P.87](#)).

Figure P.87 Piezoelectric effect applied for ignition of a gas stove-top flame.

Piezoelectric resonance

[acoustics, atomic, electromagnetism, fluid dynamics, general, mechanics, quantum] Certain materials will develop mechanical stress under the influence of electrical voltage. The crystal structure is polarized by the external application of the potential difference creating an electrical DIPOLE. The crystal will have one dominant axis of mechanical ACTIVITY. The process can also be reversed, where mechanical stress will provide an electrical potential across the crystal proportional to the MAGNITUDE of the applied stress. The electronic OSCILLATION results from the electronic configuration as described under oscillation, with a frequency: $\nu = 1/2\pi\sqrt{LC}$ and this frequency will ideally match the mechanical boundary conditions with resonance frequency: $\nu_r = 1/2\ell_1\sqrt{\rho s_{11}^E}$, where ℓ_1 is the fundamental length of compression (generally, the crystal will have three sides: $\ell_1 > \ell_2 > \ell_3$), ρ is the material density of the piezoelectric crystal, and s_{11}^E is the elastic COMPLIANCE under a constant electric field resulting from a constant electrical potential. Under ideal conditions the mechanical and electronic RESONANCE FREQUENCY will be match for optimal ENERGY conversion. Piezoelectric resonance can for instance be used in tweeter speakers for high-frequency acoustic SOUND emission (*also see* OSCILLATION and RESONANCE) (see [Figure P.88](#)).

Figure P.88 Tweeter with piezoelectric resonance-driven transverse wave emission.

Piezoelectric transducer

[acoustics, atomic, energy, fluid dynamics, general, mechanics, quantum] Around 1880 **PIERRE CURIE** (1859–1906) and **PAUL-JACQUES CURIE** (1856–1941) discover the electromechanical properties of specific ceramic crystals. One of the best known crystals is PZT: lead (Pb) zirconate (Zr) titanate (Ti): $\text{Pb}[\text{Zr}_x\text{Ti}_{1-x}]\text{O}_3$, oxygen (O), a ceramic perovskite (see [Figure P.89](#)).

Figure P.89 Chemical structure of ceramic PZT crystal: $\text{Pb}[\text{Zr}_x\text{Ti}_{1-x}]\text{O}_3$.

Piezoelectricity

[acoustics, atomic, energy, fluid dynamics, general, mechanics, quantum] The mechanism providing the means of transferring stress and strain into electrical SIGNAL, reversible electromagnetic process. Applying an electrical potential to certain materials will deform the material. Piezoelectricity is applied for microphones, pressure transducers, and ULTRASONIC IMAGING devices (both as source and detector) (*also see* **PIEZOELECTRIC EFFECT**).

Pinch effect

[atomic, nuclear] **PLASMA** effect that constricts the electric current due to the narrowing of an electric field, causing the charges to increase per cross-sectional area representative of the kinks in sausage links. Lightning bolts are a visual example of pinched plasma filaments. The pinch effect can also occur in liquid **CONDUCTOR** (LIQUID metal) or solid conductors. The process is the result of **MAGNETIC FIELD** lines. Experimentally the pinch effect is produced in Tokamak systems (plasma) with respect to **NUCLEAR FUSION** (see [Figure P.90](#)).

Figure P.90 Lightning “pinch.”

Pinch temperature

[thermodynamics] Smallest temperature difference in a steam **TURBINE** between the temperature profile for **AIR** and water, analytically equivalent to the smallest temperature difference between the cold curve and the hot curve (e.g., steam) for a heat-exchange process. The heating medium can be of any kind: **GAS** (propane, methane, etc.), gasoline, electric, coal and so forth (see [Figure P.91](#)).

Figure P.91 Pinch temperature in a heat exchanger between hot steam and cold steam.

Pinocytosis

[biomedical] The active process of LIQUID transport from the outside of the CELL MEMBRANE to the interior of the CELL by means of the formation of a vesicle. This process is part of cellular ingestion classified as ENDOCYTOSIS, which also includes solid consumption defined as PHAGOCYTOSIS. On the MECHANICS of the selective restructuring of the lipid-protein bilayer (*also see* CELL MEMBRANE) (see [Figure P.92](#)).

Role of an antigen-presenting cell

Figure P.92 Pinocytosis, would be similar to phagocytosis except for the cell consumption is liquid instead of solids. (1) Phagocytosis of enemy cell (antigen); (2) Fusion of lysosome and phagosome; (3) Enzymes start to degrade enemy cell; (4) Enemy cell broken into small fragments; (5) Fragments of antigen presented on APC surface; (6) Leftover fragments released by exocytosis.

Pion

[astrophysics/astronomy, atomic, energy, general, nuclear, quantum, thermodynamics] Elementary PARTICLE in the category of MESON. The pion was discovered in 1947, and has a mass equivalent ENERGY of $E = mc^2 = 135 \text{ MeV}$ (*also see* PI-MESON).

Pipe

[computational, fluid dynamics] Fluid conduit. Flow in pipes will generally obey the Bernoulli equation and Poiseuille's equations. Pipes will provide LAMINAR FLOW under steady state relatively low flow velocity. A straight pipe with uniform diameter has no particular geometric configurations that will provide conditions that are conducive for flow other than laminar. Junctions connecting pipes with different diameters or pipes with curvature will however provide the boundary conditions that can result in turbulent flow. Computational FLUID DYNAMICS will describe the flow in curved pipes with discrete or continuous changes in diameter due to the complex nature of the boundary conditions as a function of axial and radial location. Pulsatile flow will generate complex conditions that are not easily solved by analog means and will require in-depth computational simulation. Compliant pipe describes the flow in BLOOD vessels and has time-dependent boundary conditions and well as involves PULSATILE FLOW. For a flexible tube, the COMPLIANCE is defined as $C_{\text{compliance}} = \partial A / \partial P$, where A is the cross-sectional area of the tube and P the local pressure; this translates into a distensibility: $D_{\text{dist}} = (1/A)(\partial A / \partial P) \xrightarrow{\text{thin wall}} (2r/d)[(1 - \nu_p^2)/Y_n]$, with Y_n the Young's modulus of the tube material, ν_p the Poisson ratio, r the tube radius, and d the wall thickness. The flow (Q) in the flexible tube is approximated by the "windkessel" model as $Q = C_{\text{compliance}} (\partial P / \partial t) + (P / R_p)$, where R_p represents the peripheral RESISTANCE and t is time. This can be

developed in a FOURIER SERIES for pulsatile flow with ANGULAR FREQUENCY $\omega = 2\pi\nu$, ν the frequency: $\hat{Q} = [i\omega C_{\text{compliance}} + (1/R_p)]\hat{P}$. Because of the BOUNDARY LAYER the flow at the wall is generally stagnant and the material transport close to the boundary can be discarded by rejecting the boundary flow by applying an ORIFICE (syphoning off the boundary layer; for instance applied to transcontinental FLUID transportations). This way the flow medium may be changed but the output consistency can be pure and consistent at the core (see Figure P.93).

Figure P.93 Pipe.

P

Pipeline parameter ($\rho^n = \omega_{gr}\omega_0/2gH$)

[fluid dynamics, mechanics] Dimensionless number used in MOMENTUM transfer associated with the WATER-HAMMER phenomenon, where v_{gr} is the GROUP VELOCITY of the WAVE phenomenon, v_0 is the initial VELOCITY, g is the GRAVITATIONAL ACCELERATION, H is the STATIC HEAD. One area of interest in this is for mining and OIL drilling with regard to slurry and oil transportation. The pipeline parameter provides a metric for the hydraulic characteristics of a flow system. For instance, a value of $\rho^n > 1$ may require the use of a reflux VALVE bypassing the system's PUMP. The pipeline parameter is a means of predicting problematic circumstances and safety concerns.

Pitch

[general] Human perceptual response to frequency of acoustic ENERGY, a bass is low pitch and a flute has a high pitch. Pitch is primarily associated with the zero-order harmonic of the instrument or source of the SOUND. A related expression is from the French word "TIMBRE." The timbre denotes the base frequency as well as the spectrum, the "COLOR" of the sound of the device producing the sound (see FREQUENCY and WAVELENGTH) (see Figure P.94).

Figure P.94 French horn emitting a “rainbow” of sound i.e. frequency spectrum; analogous to an optical spectrum.

Pitot, Henri (1695–1771)

[fluid dynamics] Scientist and hydraulic engineer from France. The PITOT TUBE for measuring flow velocity was named after him. He also gained fame for the design of the aqueduct in Montpellier, France; the aqueduct saint Clément de Montpellier also called the aqueduct Pitot (see [Figure P.95](#)).

Figure P.95 Henri Pitot (1695–1771).

Pitot theorem

[computational] The opposite sides of a quadrilateral (four-sided closed outline of regular or irregular shape; special case rectangle) enclosing a circle are equal to the sum of the remaining sides: $AB + CD = BC + DA$. Proposed by the French engineer and mathematician HENRI PITOT (1695–1771) in 1725 (see [Figure P.96](#)).

Figure P.96 Pitot theorem.

Pitot tube

[fluid dynamics] Tube invented by the French scientist and engineer HENRI PITOT (1695–1771), later modified by the French engineer Henry Darcy (1803–1858) and is widely used to measure flow velocity, specifically for airflow around the WING of a plane or water flow speed for a boat as well as TURBINE generators/engines. The Pitot tube is relatively narrow, open on one side, facing upstream and is connected to a MANOMETER on the opposite side, providing the stagnation pressure (P_t) also referred to as the total pressure. The principle relies on Bernoulli's theorem. In a modified form, the static pressure (P_s) is measured by placing small perforations in the WALL of the tube. The flow velocity (v) is defined as $v = \sqrt{\{2(P_t - P_s) / \rho\}}$, where ρ is the density of the flow medium. The flow velocity is an indirect means of determining the velocity of the craft. Ice formation in the Pitot tube could have been the cause of several airplane accidents in the past, and nowadays it is hence heated (see [Figure P.97](#)).

Figure P.97 Pitot tube on the nose of the plane.

Pixel

[imaging, theoretical] Smallest unit area on sensor array with uniform intensity of all spectral lines due to the fact that it is a self-confined single ELEMENT as part of a larger detector or display raster assembly. Generally, the pixel is part of a two-dimensional arrangement, forming a component of an IMAGE: a picture element. Pixels are describing the sensor ELEMENTS of a CAMERA as well as the display elements of a screen. The sensing elements can be components of a CCD CAMERA, alternatively the RGB-LED (red-green-blue–light emitting diodes) clusters or LCD (LIQUID crystal display) sections on a visual display unit (see [Figure P.98](#)).

Figure P.98 Images constructed for low-resolution pixels, each individual single-colored square.

Planck, Maxwell Karl Ernst Ludwig (1858–1947)

[atomic, computational, energy, general, nuclear, thermodynamics] German scientist. Introducer of the concept of QUANTUM THEORY in 1900. The theoretical concept of the fact that ELECTROMAGNETIC

RADIATION has a discrete ENERGY SPECTRUM was derived from Planck's experimental and theoretical work on BLACK-BODY RADIATION. In 1905, ALBERT EINSTEIN (1879–1955) substantiated the work of Max Planck by his introduction of the PHOTON-PARTICLE DUALITY theory (see [Figure P.99](#)).

Figure P.99 Maxwell Karl Ernst Ludwig Planck (1858–1947).

Planck's Constant h

[atomic, computational, electromagnetism, energy] A natural constant of proportionality relating the frequency of a quantum of ENERGY to the total energy of the QUANTUM, $h = 4.1356692 \times 10^{-15}$ Js. Often the derived Planck's constant "h-bar:" $\hbar = h/2\pi$, introduced by PAUL ADRIEN MAURICE DIRAC (1902–1984) is used in simplified equation format.

P

Planck's law

[atomic, nuclear] See **PLANCK'S RADIATION LAW**.

Planck's radiation law

[atomic, nuclear] Black-body RADIATION spectral definition by MAX PLANCK (1858–1947) in response to a challenge by Kirchhoff in follow-up on the Kirchhoff radiation law: $\epsilon_\lambda/\alpha_\lambda = I_\lambda$, where ϵ_λ represents the radiated ENERGY as a function of the wavelength (λ), α_λ the fraction of absorbed energy, and I_λ the energy incident on the "black-body." Combining this with the WIEN'S DISPLACEMENT LAW and the energy (E) quantization: $E = h\nu$, with $h = 4.1356692 \times 10^{-15}$ Js the PLANCK CONSTANT, and $\nu = c/\lambda$ the frequency

(c the speed of light). This led Planck to derive the spectral energy distribution: $I_\lambda = 2\pi hc^2/\lambda^5 \left(e^{hc/\lambda k_B T} - 1 \right)^{-1}$, with $k_B = 1.3806488 \times 10^{-23} \text{ m}^2 \text{ kg/s}^2 \text{ K}$ Boltzmann's constant, and T temperature (see [Figure P.100](#)).

Figure P.100 Planck's radiation law.

Plane of incidence

[general] The local surface area with the normal vector indicating the largest congruent area with equal vector representation. The plane of incidence makes an ANGLE with the vector of the direction of propagation of the incident ENERGY form (PARTICLE OR WAVE).

Plane of polarization

[general] The plane in which the direction of the electric field of ELECTROMAGNETIC RADIATION is directed (see POLARIZATION) (see [Figure P.101](#)).

Figure P.101 The light reflected from the seawater is polarized in the horizontal direction, which is suppressed when viewing through the polarizer filter, reducing the glare.

Plane wave

[general, optics] $U(\vec{r}) = \mathcal{A}e^{ik\vec{r}}$, where $k = 2\pi/\lambda$ is the wavenumber, $\vec{r}$ the vectorial DISTANCE to the source, and $\mathcal{A}$ a constant (i.e., AMPLITUDE). The plane wave SOLUTION follows from the Euler theorem.

Plane-polarized waves

[general] ELECTROMAGNETIC RADIATION with the electric field in a fixed single direction. Generally, ordinary light-sources emit unpolarized light, with POLARIZATION direction that is continually changing with no fixed pattern of direction, or for a single time frame, the LIGHT will be a combination of photons that form a ray that can be considered to consist of elliptically (circularly) polarized light with a random combination of electric field directions (see [Figure P.102](#)).

Figure P.102 Plane wave.

Planet

[general] In general, galactic material in our SOLAR SYSTEM has to satisfy the following three criteria in order to classify as planets: (1) the material needs to orbit around the SUN in a regular pattern, (2) the material needs to have enough mass to generate a cohesive gravitational force that constrains the orbiting mass into a spherical geometry, and (3) the mass in orbit needs to be cohesive, collecting all mass in the same orbiting pattern (i.e., no debris in the same path), as defined by the International Astronomical Union (IAU). As a result Pluto was recently discarded as a qualified planet leaving only 8 planets in our Solar system; from the Sun outward: Mercury, VENUS, EARTH, MARS, JUPITER, SATURN, Uranus, and Neptune. Two additional dwarf planets at the outer edge of our Solar system have been recognized in orbit but with debris: Pluto and Eris, where Eris and Pluto are relatively close and Eris was discovered fairly recently. The ASTEROID Ceres also meets those requirements postulated by the IAU and hence is a dwarf planet as well (see [Figure P.103](#)).

Figure P.103 Planets.

Planetary data

[astrophysics/astronomy, computational] The SOLAR SYSTEM consists of the SUN in the center with planets orbiting around it from the inside to the outside, conventionally: Mercury, VENUS, EARTH, MARS, JUPITER, SATURN, Uranus, Neptune and Pluto; with Jupiter the largest (about 11 times the diameter of Earth). However, certain philosophies are considering Pluto to be a dwarf PLANET (size one-fifth the diameter of Earth, our MOON has a diameter that is one quarter of Earth's diameter on average) and may not be counted as a full planet, making Neptune the outermost planet. Most recently another planet (dwarf) at the outer extremity has been added, for instance Eris. Additionally, Pluto has a substantial size moon: Charon, which makes the orbit of Pluto go inside the orbit of Neptune for nearly 20 years (total solar orbit 248 earth-years). Pluto's moon, Charon, makes it a double planet. Pluto has a total of three moons, two of which very small (*also see SOLAR SYSTEM, and respective planets*) (see [Figure P.104](#)).

Figure P.104 Planetary system and galactic objects.

Planetary motion

[astrophysics/astronomy, general, geophysics] The planets in orbit around the SUN primary are responding to the gravitational attraction by the Sun, which represents 99.9% of all the mass in our SOLAR SYSTEM. The orbiting planets do however influence the ORBITS of neighboring planets under a perturbation effect, making the orbits deviate from the perfect ellipsoidal pattern. The orbital velocity (v_o) of each planets results in first-order approximation on the CENTRIPETAL FORCE balancing the gravitational force: $v_o = \sqrt{(GM_{\text{sun}}/r)}$, where G is the gravitational constant, M_{sun} the mass of the Sun, and r the respective planetary DISTANCE to the Sun. Please note that the orbits are not perfectly circular (*see KEPLER'S LAW*) (see [Figure P.105](#)).

Figure P.105 Graphical representation of the relative size within our Solar system.

Planetary motion, Kepler's laws of

[astronomy/astrophysics, general, geophysics] See **KEPLER'S LAWS**.

Planetary orbits

[computational, geophysics] See **KEPLER'S LAW**, as described by **JOHANNES KEPLER** (1571–1630).

Planetary precession

[astrophysics/astronomy, general, geophysics] Precession of a planet's **SPIN** axis, in addition to the “wobble” of the Earth's axis every 26 000 years. For the **EARTH**, the precession angular tilt (ϕ) with respect to the normal to the **INVARIABLE PLANE** (the Laplace plane), which is inclined to the planetary equator by ϑ . The spatial orientation of the planetary orbit can be described by the **EULER ANGLES** for the ecliptic and **EQUINOX** position (respectively: φ, ω, Ω). This **PRECESSION** can be described under the assumption that the variations induced by the **MOTION** resulting from the **SUN** and its own satellites (planetary perturbations, as well as our own **MOON**) is given as $\partial\phi/\partial t = -(3/2)(MR_e^2/I_c\omega_s)J_n n^2 \{\cos\epsilon_e + \sum_j [(n_j/n)^2 [M_j/(M_j + M)] \cos(\epsilon_e - \vartheta_j)]\}$, where M is the mass of the **PLANET** in precession, R_e is the planetary radius, J_n are harmonic coefficients (also referred to as zonal coefficients; derived from the Legendre polynomials [Legendre functions: P_{nj} ; for instance, $P_{00} = 1$, $P_{10} = x$, $P_{20} = (3x^2 - 1)/2$, etc.]), ω_s is the angular spin of the planet, I_c is the moment of **INERTIA** for the polar axis, M_j is the mass of adjacent planets and satellites (**SATELLITE** is a term introduced by **JOHANNES KEPLER** [1571–1630]), $n = d/dt(\varphi + \omega + \Omega)$ is the orbital mean displacement motion for the planet with respect to the Sun, and ϵ_e is the inclination of the equator with respect to its orbit. Note that the seasons on Earth are the result of the orbital position of the Earth with respect to the Sun and the **ANGLE** of the Earth's axis in the rotational plane creating the seasons: summer, autumn, winter, and spring. The presumably fixed angle of the Earth's axis in the solar orbit is however affected by the Earth's precession and will cause the seasons to shift.

Planetary vorticity

[dynamics, general, geophysics] See **CORIOLIS FREQUENCY**.

P

Plasma

[atomic, biomedical, general, nuclear] One of the four states: solid, **LIQUID**, vapor/gas, and plasma. A plasma is a condition of a medium where the electrons of a significant number of atoms have been removed and flow freely, mixture of atoms, ions, and electron clouds, existing predominantly at high temperature, however, with a high density that does not correspond to the otherwise “gaseous” behavior of the plasma medium. Plasma generally has a luminous behavior, for instance a sodium lamp, fluorescent lamp, or “neon” lamp are plasma **LIGHT** sources. The **SUN** is also a plasma as well as a **NUCLEAR FUSION** reactor. Additionally, **BLOOD** is composed of plasma as the main fluid, with red and white blood cells and dissolved proteins, next to **GLUCOSE**, clotting factor (providing the means to congeal/coagulate blood—forming a

“scab;” also provides the mechanism to form blood clots [thrombus]) and electrolytes, dissolved carbon dioxide (carbolic ACID) and hormones and enzymes and more (see [Figure P.106](#)).

Figure P.106 Plasma.

Plasma frequency

[atomic, nuclear] Oscillations within a PLASMA resulting from the electron thermal velocity (v_e). The wavelength of the OSCILLATION (λ_D) has the Debye length $\lambda_D = v_e / 2\pi v_{pe}$, with frequency dominated by the free electron density (n_e): $v_{pe} = \omega / 2\pi = \sqrt{(n_e e / \pi m_e)} = 8.97 \sqrt{n_e}$ Hz, where m_e is the electron mass and e is the electron charge. The plasma oscillation phenomenon was observed by the American chemist and physicist IRVING LANGMUIR (1881–1957) in 1929.

Plasmon

[atomic, nuclear] Quantum of OSCILLATION energy in a PLASMA, defined as $E_{pl} = \hbar \sqrt{(4\pi n_e e^2 / m_e)}$, with $\hbar = h / 2\pi$ ($h = 4.1356692 \times 10^{-15}$ J s the PLANCK'S CONSTANT), n_e the free electron density, m_e the electron mass, and e the electron charge.

Plastic strain

[geophysics, mechanics] Permanent deformation in shape or size of an entity without resulting in destructive fracture, which may accumulate over time as the result of a sustained stress that exceeds the elastic yield point for the constitution of the material. Plastic strain can be expressed as a POWER LAW defined as the strain rate ($\dot{\epsilon}_s = \dot{\epsilon}_s$), linking applied stress (σ_s) to the activation ENERGY for deformation (Q_{ac}), the prevalent temperature (T) as $\dot{\epsilon}_s = A\sigma_s^n \exp(-Q_{ac}/RT)$, where n is the heuristic power function constant, which is derived from experimental data, A is an arbitrary material constant, and $R = 8.3144621(75) \text{ J/K mol}$ the GAS constant. For an perfect viscous fluid, $n = 1$. Beyond plastic behavior the material will rupture. Materials can be “hardened” or “softened” to modify the plastic strain behavior. In GEOPHYSICS, the elastic–plastic behavior applies to the crust and mantle of the EARTH. Rheological stratification of the continental crust under stress can be defined with integral application of brittle friction and plastic flow. Deformation can occur in several ways: plastic, ductile, and brittle. Ductile materials will accumulate any permanently applied stress without macroscopically visible signs of fracture until the ELASTIC LIMIT is reached, at which point the material will disintegrate. Brittle deformation will experience MICROSCOPIC deformations, where grains of material will slide along each other and will break (crumble) past the yield point of the material. Viscoplasticity, in particular, is used to describe the flow of lave (*also see CREEP*) (see [Figure P.107](#)).

Figure P.107 Plastic strain.

P

Plasticity

[biomedical, chemical, mechanics] Process of irreversible deformations that are presumably based on an atomic scale, in biology on a cellular composition scale (in reference to stem cells). The deformations are formed when a threshold level or ELASTIC LIMIT is exceeded. The applied stress under plastic deformation is referred to a flow STRESS (see [Figure P.108](#)).

Figure P.108 Plasticity of an automobile, absorbing the external forces in deformation.

Plasticizers

[biomedical, chemical, mechanics] “Weak-makers,” phthalates. Chemical additives that will makes PLASTICS more pliable and maneuverable.

Plastics

[chemical, mechanics] Chemical grouping of organic polymers that are deformable, generally derived from both plant-based (e.g., CELLULOSE, from cotton; vegetable oils from seeds), naptha (natural gas) or oil-based ingredients. The ingredients are called resins. Plastics are for instance polypropylene and polyethylene. The building blocks are, for instance, propylene, ethane, and ethane (monomers), which are constructed into polymers. Polymerization can be accomplished either by means of addition or in condensation reactions; sometimes the POLYMER is formed at the interface of two LIQUID layers of different media. Plastics are frequently manufactured as composite materials. Not all plastics formed from plant-based ingredients are biodegradable, since the same monomers are formed in comparison to oil-based plastics. Plastics are usually formed into shape by injection molding or pressing/stamping (see [Figure P.109](#)).

Figure P.109 Plastics.

Plato (427–347 BC)

[general] Original name “Aristocle,” Greek scientist and philosopher, and founder of the modern concepts of optics and sight, contradicting the EXTRAMISION theory of VISION of his peers. However, his work was not recognized millennia later, after the publications by LEONARDO DA VINCI (1452–1519). Other work by Plato involves the description of MAGNETISM (*also see* LOADSTONE) in support of the work by Socrates

(469–399 BC). In MECHANICS, Plato had postulated the CONSERVATION OF ENERGY concept in his description of the exchange between heat and ACTIVITY (i.e., kinetic ENERGY) (see [Figure P.110](#)).

Figure P.110 Plato (427–347 BC), artistic impression statue at the Louvre in Paris, France.

Plücker, Julius (1801–1868)

[atomic, general, nuclear] Scientist from Germany (Prussian empire). Plucker realized that when the pressure in a CATHODE ray tube is low, the GLASS wall at the opposite side can be made to emit light. The location where LIGHT is emitted can be altered by applying a MAGNET to the side WALL of the tube.

He interpreted the light emission and MAGNETIC manipulation with the presence of ELECTRIC CHARGE and indirectly indicated the discovery of the electron in 1858 (see [Figure P.111](#)).

Figure P.111 Julius Plücker (1801–1868).

Plutonium ($^{244}_{94}\text{Pu}$)

[atomic, nuclear] Artificially produced radioactive ELEMENT. Plutonium-244 is very stable with a half-life of 82 000 000 years, decays into $^{240}_{92}\text{U}$ by ALPHA DECAY. Plutonium ($^{238}_{94}\text{Pu}$, plutonium isotope) was first made at the University of California in 1941 by high-speed collision of deuterons on uranium-238. Plutonium-238 is used as nuclear fuel on space ships. The Cassini probe and the Galileo probe are powered under thermo-nuclear reactors from plutonium-238. Another ISOTOPE, plutonium-239 has a FISSION reaction mechanism and used in nuclear weapons and certain NUCLEAR REACTOR power generators (see [Figure P.112](#)).

Figure P.112 Plutonium.

Plutonium Project

[general] See **MANHATTAN PROJECT**.

PMM1

[thermodynamics] **PERPETUAL MOTION** machine of the first kind. A hypothetical system with a cyclic process that does not endure an internal change in state (no **ENERGY** transfer); however, it produces work. There is a theoretical impossibility of such a device in existence or ever being developed since there is no energy produced but work would follow nonetheless.

PMM2

[thermodynamics] **PERPETUAL MOTION** machine of the second kind. A lossless mechanism based on a cyclic change in state that results in work. The number of constituents in the system will not change from state to state. This system is impossible to achieve. Assuming that there are different ways of achieving this process, one process is from one stable equilibrium, performing work, and reaching a new equilibrium with lower **ENERGY**. After subsequent work performed on the system, the new state will reach a **NONEQUILIBRIUM STATE**, which should be equivalent to the starting state but cannot be equivalent since the first state was an **EQUILIBRIUM STATE** and the third state is not.

Pneumotachometer

[biomedical, fluid dynamics] Device for measuring **GAS** flow in addition to the pressure difference over the device from input (pressure at the source) to output (external, ambient pressure). One particular application is in measuring the exhaled and inhaled breath and deriving the associated lung-volume (see [Figure P.113](#)).

Figure P.113 Pneumotachometer.

pn-junction

[electronics, general] Junction of a *p*-type material and an *n*-type material, forming a **DIODE**. The *p*-type material has a shortage of electrons (holes), while the *N-TYPE SEMICONDUCTOR* material has been treated to have a permanent surplus of electrons. The *pn*-junction forms a semiconductor diode. The **SCHOTTKY DIODE** is a metal–semiconductor *pn*-junction diode that uses the work function between the **METAL** and the semiconductor material to yield a **SCHOTTKY BARRIER**. The Schottky diode has **RECTIFIER** characteristics, with current profile: $I = I_r \left\{ \exp\left(\frac{qV}{nk_B T}\right) \right\} - 1$, where I_r represents the reverse leak current, q the charge, V the applied voltage, qV represents the bias potential, n is a factor that represents the idealistic character ($n = 1$ would be a perfect diode, $k_B = 1.3806488 \times 10^{-23} \text{ m}^2 \text{ kg/s}^2 \text{ K}$ the Boltzmann coefficient, and T the temperature at the junction. Step recovery diodes are *p-n* diodes with extremely fast recovery time due to the designed graded **FERMI-LEVEL** drop at the junction, thus minimizing the dwell time of the minority charge carriers. A **Zener**

diode is a p - n diode with a well-defined and sharp reverse bias breakdown voltage (up to several hundred volt). Another type of p - n diode is the tunnel diode. The tunnel diode has greater than average DOPING of both n - and p -TYPE SEMICONDUCTOR materials resulting in a Fermi level that is in the valence band for the p -type material and for the n -type material the Fermi level is in the CONDUCTION BAND (see Figure P.114).

Figure P.114 *pn*-junction.

PNP transistor

[general] Semiconductor sandwich with *N*-TYPE SEMICONDUCTOR material has been treated to have a permanent surplus of electrons electronically positioned between two *p*-type materials with respective permanent shortage of electrons (holes). One *p*-type material is the “collector” while the other is the “emitter” and the *n*-type material provides the current quenching mechanism as the “base.” Transistors can be used to make rudimentary amplifier circuits with power supplies and resistors. The current gain for the TRANSISTOR is the collector current (ΔI_C) to base current (ΔI_B) ratio: $\text{gain} = \Delta I_C / \Delta I_B$, and similarly for the voltage gain (see [Figure P.115](#)).

Figure P.115 (a–c) PNP transistor.

Po₂

[biomedical, chemical, fluid dynamics, general] Partial pressure of oxygen in a system, mixture of gasses. Gasses can be freely dispersed in liquids or chemically dissolved in fluids. In biomedical applications, this is used to determine the oxygen SATURATION of BLOOD with a PULSE OXIMETER (see RESPIRATION and PULSE OXIMETRY) (see [Figure P.116](#)).

Figure P.116 Graphical representation of the partial pressure of oxygen, in particular, relevant to respiration.

Pockels, Friedrich Carl Alwin (1865–1913)

[general, optics] Physicist from Italy. Pockels is best known for his research how in certain birefringent materials the refractive index can be altered under the influence of an externally applied electric field (see [Figure P.117](#)).

Figure P.117 Friedrich Carl Alwin Pockels (1865–1913). (Courtesy of Technische Universität Dresden, Germany.)

Pockels effect

[electromagnetism, energy, general, optics, thermodynamics] Change in the optical axis of a medium linear to the MAGNITUDE of an externally applied electric field, observed and described by FRIEDRICH CARL ALWIN

POCKELS (1865–1913) in 1893. Also considered to be part of the BIREFRINGENCE phenomenon. The local INDEX-OF-REFRACTION (n) can be described in a first-order Taylor series to depend on the local magnitude (location $\vec{r}$) of the ELECTRIC FIELD (E) as a function of time expressed as $n(E, \vec{r}, t) = n(\vec{r}, t) + [dn(\vec{r}, t)/dE]E(\vec{r}, t)$. The effect is used in the Pockels CELL for modulation of a beam of LIGHT, specifically in laser design, used in the MODE-LOCKED LASER (also see KERR EFFECT) (see Figure P.118).

Figure P.118 The use of the Pockels effect in the Pockels cell, used to temporarily interrupt laser emission, creating a mode-locked laser beam.

Poincaré, Jules Henri (1854–1912)

[computational, general, thermodynamics] Theoretical physicist from France. Additionally, he was a mathematician and engineer. His computation work describes the shape of a rotating sphere turning into a “pear shape” in correlation with the momentum $L = I\omega$, where ω represents the ANGULAR VELOCITY and I the MOMENT OF INERTIA (which is a direct function of the shape of the revolving body). His most well-known work describes the MECHANICS of a rotating FLUID published in 1885: *Sur l'équilibre d'une masse fluide animée d'un mouvement de rotation*, in the *Acta Mathematica*. This work appears to be in follow-up of the work by CARL JACOBI (1804–1851) and COLIN MACLAURIN (1698–1746). The main reference of this work relates to the swing of a PENDULUM (see Figure P.119).

Figure P.119 Jules Henri Poincaré (1854–1912).

Poincaré section

[computational] Mechanism designed to discover structure in an attractor. The attractor for a dynamic system is the outlined CONTINUUM of physical parameter that the system tends to achieve irrespective of the starting conditions by physical evolution. The attractor can be plotted in a multidimensional graph. The Poincaré section follows from placing an arbitrary plane in the attractor graph and the orbit of the evolution of the attractor mechanism will intersect with the plane on several locations, which provides the marking outline for the Poincaré plane or section, providing an indication of structure of the attractor and hence the processes involved. Part of “chaos” theory.

Poinsot, Louis (1777–1859)

[mechanics] Physicist and mathematician from France. Poinsot is considered the father of geometrical MECHANICS. He was a contemporary, and colleague of French mathematician AUGUSTIN LOUIS CAUCHY (1789–1857) and the Italian mathematician JOSEPH-LOUIS LAGRANGE (1737–1813), all working at the École Polytechnique in Palaiseau near Paris, France (see [Figure P.120](#)).

POINSOT,

(Paris)

Membre de la Légion d'honneur.

1777-1859

Figure P.120 Louis Poinsot (1777–1859), engraved by Julien-Leopold Boilly.

Poinsot motion

[mechanics] Phenomenon in the Euler equation of MOTION calculations where two PRINCIPAL MOMENTS of inertia have the same value and direction, while only one force is present. Examples of Poinsot motion are found in gyroscopes and a spinning top. The Poinsot method was developed by LOUIS POINSOT (1777–1859) in 1809, which uses graphical interpretations of a body in MOTION based on conservation of KINETIC ENERGY and conservation of momentum. The KINETIC ENERGY (KE) of a rotating body with MOMENT OF INERTIA (I) and ANGULAR VELOCITY ω can be written, using the coordinate substitution $\bar{\rho}_m = \bar{\omega} / \sqrt{(2KE)}$, as $KE = (1/2)(I_1\omega_1^2 + I_2\omega_2^2 + I_3\omega_3^2)$, which yield: $I_1\rho_{m1}^2 + I_2\rho_{m2}^2 + I_3\rho_{m3}^2 = 1$, which is a description of an ellipsoid. The rotating ellipsoid in the graph represents the force-free motion, and the tangent plane is called the invariable plane (see [Figure P.121](#)).

Figure P.121 Poinsot motion.

Point charges

[computational, general] Mathematical approximation for a geometry that is much larger than the source to allow for disregarding the boundary effects of the phenomenon in the SOLUTION of the situation. All charges are clumped together on an object of infinitesimal small size, or the charge itself is a single electron or PROTON charge. When the DISTANCE to the collection of charges is much greater than the diameter of the charge cloud the local effects of the charges are experienced as if they originate from the center of the charge collection. The point charge ($Q = \sum_i q_i$) will generate a Coulomb field at distance r resulting from Gauss' law expressed as $E_{\text{elec}} = (Q/4\pi\epsilon r^2)\vec{r}$, where $\epsilon = \epsilon_r\epsilon_0$, with $\epsilon_0 = 8.85419 \times 10^{-12} \text{C}^2/\text{Nm}^2$ the permittivity of free space and ϵ_r the RELATIVE PERMITTIVITY of the medium.

Point source

[acoustics, mechanics, optics] Any ENERGY representation that is considered to be located in an infinitesimally small volume at a single location in three-dimensional space. The size of the source often is taken with respect to the observed phenomena. The source will be isotropic and produce a SPHERICAL WAVE pattern. In certain approximations, the SUN can be considered a point source. In ACOUSTICS, a point source is for instance the emission from a piezoelectric device or SPEAKER, for this the ACOUSTIC INTENSITY will DECAY with $I \hat{=} 1/r^2$, whereas the pressure will decay as $P(r) \hat{=} 1/r$ with r the DISTANCE to the source. A point source can also be referenced as a mono-pole (mono-pole). The emitted wave front over TIME (t) will obey the WAVE EQUATION: $[\Delta - (n'/c^2)(\partial^2/\partial t^2)]V(\vec{r}, t) = 0$, where $\Delta = (\partial^2/\partial x_1^2) + (\partial^2/\partial x_2^2) + (\partial^2/\partial x_3^2) + \dots + (\partial^2/\partial x_m^2)$ is the Laplace operator for m -dimensional space, $V(\vec{r}, t)$ the phenomenon (in which case this represents harmonics the function becomes FREQUENCY ($\nu = \omega/2\pi$) dependent: $V(\vec{r}, t, \omega)$; acoustic electromagnetic etc., $n' > 1$ a constant, and c the speed of propagation of the phenomenon (e.g., speed of sound, speed of LIGHT). The spatial components of the wave equation will satisfy the Helmholtz equation. For an acoustic point source, the INTENSITY (I) over a period (T) is the average from the pressure and the PARTICLE motion ($v(\vec{r})$) expressed as $I = (1/T) \int_0^T P(\vec{r}, t) v(\vec{r}, t) dt$

Point vortex

[computational, fluid dynamics] In FLUID DYNAMICS the calculation of the CIRCULATION ($\Gamma = \oint v d\vec{l} = \int (\Delta \times \vec{v}) \cdot d\vec{s}$, where v is the velocity at the boundary of the tube generating the vortex, $\Delta = (\partial^2/\partial x_1^2) + (\partial^2/\partial x_2^2) + (\partial^2/\partial x_3^2) + \dots + (\partial^2/\partial x_m^2)$ the Laplace operator for m -dimensional space and $\vec{s}$ the surface with circumference c) associated with for instance a RANKINE vortex tube can be approximated for vanishing CROSS SECTION to provide the point vortex $\Gamma = \pi a^2 \omega_0 = \text{Constant}$, with ω_0 the angular velocity of rotation and $a \downarrow 0$ the vanishing radius (at which $\omega_0 \rightarrow \infty$) (see Figure P.122).

Figure P.122 Point vortex.

Poise (P)

[fluid dynamics, general, mechanics] Unit for DYNAMIC VISCOSITY, specifically in reference to liquids. One poise is equal to one-tenth pascal-second: $1P = 0.1 \text{ Pa s}$. The poise is named after the French physiologist POISEUILLE, JEAN LEONARD MARIE (1799–1869).

Poiseuille, Jean Leonard Marie (1799–1869)

[fluid dynamics] Scientist and physiologist from France. Jean Poiseuille introduced a range of flow concepts with wide ranging implications (see [Figure P.123](#)).

Figure P.123 Jean Leonard Marie Poiseuille (1799–1869).

P

Poiseuille flow

[fluid dynamics] Laminar flow in a horizontal tube with diameter D , with PRESSURE (P) drop in direction $\hat{x}$ that can be described by the POISEUILLE LAW, with flow velocity ($v(r)$) profile as a function of radius (r):

$v(r) = (1/16\eta)(dP/d\hat{x})(D^2 - 4r^2)$, where η is the viscosity of the LIQUID in flow.

Poiseuille number ($Ps = v_{ph}\eta/gd_p^2(\rho_s - \rho_f)$)

[fluid dynamics] Dimensionless number indicating the ratio of the net viscous force to the gravitational force, where v_{ph} is the PHASE VELOCITY of the WAVE phenomenon, η the KINEMATIC VISCOSITY, g GRAVITATIONAL ACCELERATION, d_p the (average) PARTICLE diameter, and ρ_s and ρ_f the respective density of the solid and the FLUID. The Poiseuille number applies primarily to LAMINAR FLOW conditions, and is mainly a function of the duct shape (e.g., circular, parallel plates).

Poiseuille's law

[biomedical, fluid dynamics] (also known as the Poiseuille equation) Expression for the flow rate through a horizontal tube as a function of the radius to the fourth power expressed by JEAN LEONARD MARIE POISEUILLE (1799–1869) in 1840. The average flow rate (Q_{flow}) is represented with respect to the radius of the tube (R) over a characteristic length (L) with a pressure gradient ($P_1 - P_2$) as

$Q_{\text{flow}} = (\pi R^4 / 8\eta) [(P_1 - P_2) / L]$, where η is the viscosity of the liquid in flow. The use of Poiseuille's law to define BLOOD flow has limited validity due to the nonlaminar behavior and the fact that the vascular walls are compliant, next to the influences of the direction of flow in an upright body, which may also be in MOTION. Also found under HAGEN-POISEUILLE LAW, with the independent contributions of the Prussian (now his birthplace is in Russia) scientist GOTTHILF HEINRICH LUDWIG HAGEN (1797–1884).

Poisson, Siméon Denis (1781–1840)

[astrophysics/astronomy, biomedical, computational] Physicist and mathematician from France, with additional training in MEDICINE. Poisson was a pupil of GIUSEPPE LUIGI COMTE DE LAGRANGE (1737–1813), ADRIEN-MARIE LEGENDRE (1752–1833) and PIERRE-SIMON DE LAPLACE (1749–1827). Poisson contributed to the interpretation and development of differential equations and partial differential equations. Siméon Poisson elaborated on the work by JOHANNES KEPLER (1571–1630) on the perturbations by planets and provided elaborate descriptions of charge migration as well as DIFFUSION characteristics and properties next to HEAT TRANSFER in association with SADI NICOLAS LÉONARD CARNOT (1796–1832). Siméon Poisson replaced ÉTIENNE LOUIS MALUS (1775–1812) on his death at the École Polytechnique in 1812. His mathematical work under Laplace also influenced the work of GEORGE GREEN (1793–1841) (see [Figure P.124](#)).

Figure P.124 Siméon Denis Poisson (1781–1840).

Poisson brackets

[computational] Recursive process of differentiation, extending out over partial differential equations; for instance applied to two functions f and g with variables p and q , this yields $\{f(p, q), g(p, q)\} = [(\partial f / \partial p)(\partial g / \partial q)] - [(\partial f / \partial q)(\partial g / \partial p)]$. In differential equations, the Poisson brackets provide a Hamiltonian operation (H) in MECHANICS as a binary operation. The connection with the Hamiltonian in mechanics is as follows: $\dot{p} = \{p, H(p, q)\}$, respectively, $\dot{q} = \{q, H(p, q)\}$. The Poisson brackets are an integral part of the HAMILTONIAN EQUATIONS OF MOTION. Specific rules associated with the Poisson brackets in differential expressions are $\{f, g\} = -\{g, f\}$; $\{f, f\} = 0$; $\{f, gb\} = g\{f, b\} + \{f, g\}b$; and $\{f, \{g, b\}\} + \{b, \{f, g\}\} + \{g, \{b, f\}\} = 0$, which are all natural properties of QUANTUM operators.

Poisson distribution

[computational] PROBABILITY theory describing the distribution of obtaining exactly n successes in N trials, as the limit of a binomial distribution $P_\chi = \lim_{n \rightarrow \infty} \{[N! / n!(N - n)!] p^n (1 - p)^{N - n}\}$, where P represents the probability and $\chi = Np$ the expected number of successes. The Poisson distribution is maximized under the condition $dP_\chi(n) / dn = 0$. The Poisson distribution was the brain child of SIMÉON DENIS POISSON (1781–1840).

Poisson equations

[biomedical, chemical] **DIFFUSION** of charges. $\nabla \cdot \vec{j} = d\rho_{\text{charge}}/dt = \nabla \cdot \gamma_{\text{cond}} \vec{E} = \gamma_{\text{cond}} (\nabla \cdot \vec{E}) = -\gamma_{\text{cond}} (\nabla^2 \Phi)$, where the first part expresses the continuity of charge, $\nabla^2 \Phi = \rho_{\text{charge}}/\epsilon = \nabla \cdot \vec{j}/\gamma_{\text{cond}}$, $\vec{E}$ the electric field, γ_{cond} the electrical conductivity of the medium, $\vec{j}$ the charge **FLUX** (per unit area), Φ the potential difference across the **BARRIER**, which is the **CELL MEMBRANE** in biology, ∇^2 the Laplace operator, ρ_{charge} the charge density, and $\epsilon = \epsilon_r \epsilon_0$, with $\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{Nm}^2$ the permittivity of free space and ϵ_r the **RELATIVE PERMITTIVITY** of the medium, introduced by **SIMÉON DENIS POISSON** (1781–1840).

Poisson noise

[biomedical, electronics, electromagnetism] Random **SIGNAL** fluctuations in the registered detector value resulting from a limited **PHOTON** count. The source may be powerful enough, however, due to attenuation in a medium the photon count can be drastically reduced. The limited photon count may not reach threshold values for conversion into an electrical signal, but cumulative events may provide electron release. Photon emission during **X-RAY RADIATION** provides an example of the random generation of the X-ray photons in the emission process. Poisson noise stands in comparison to **GAUSSIAN NOISE**. Poisson noise is based on the initial efforts and conclusions by **SIMÉON DENIS POISSON** (1781–1840) on general phenomenological description.

Poisson's ratio (ν_p)

[fluid dynamics, geophysics, mechanics] Quotient of extensions normal to the **PRINCIPAL STRESS** vector over extensions parallel to the principal stress vector: $\nu_p = -\epsilon_x/\epsilon_y$, where ϵ_i is the strain in direction i . Note that Young's modulus is stress over strain. Poisson's ratio can, in geological applications, be derived from **SEISMIC WAVE-velocity** vector comparison. For a compressible medium $\nu_p < 0.5$, whereas for an incompressible medium $\nu_p = 0.5$.

Polar coordinates

[biomedical, computational, fluid dynamics, mechanics] Two-dimensional outline with two references; the **DISTANCE** with respect to a fixed origin, conveniently chosen, and the angular dependency with respect to a conveniently chosen reference line through the origin. This is superseded in three dimensions by cylindrical coordinates or alternatively spherical coordinates (see [Figure P.125](#)).

Figure P.125 Polar coordinates.

Polar moment of inertia

[biomedical, computational, mechanics] Geometrical outline of the distribution of the points within an arbitrary area ($\mathcal{A}$) for a two-dimensional “object” in relation to an axis of choice: $J_{\text{axis}} = \int_{\mathcal{A}} r_p^2 d\mathcal{A} \xrightarrow{\text{to } x\text{-axis}} \iint_{\mathcal{A}} y_p^2 dx dy$, where r_p represents the DISTANCE to the axis of choice. This is also known as the MOMENT OF INERTIA of a plane area, or the second moment area.

Polar nature of a medium

[biomedical, chemical, fluid dynamics, mechanics, thermodynamics] Materials (especially liquids) can on a molecular level be inertly polarized or can be induced to shift their ELECTRIC CHARGE concentration to create the equivalence of a DIPOLE. Water is a clear example of the natural polarity due to the arrangement of the two hydrogen atoms with respect to the single oxygen ATOM, where the hydrogen is arranged asymmetrically, with both atoms approximately at 120° with each other. Oils on the other hand are nonpolar. Both alcohols and the general classification of detergents are a special case that can mix with both water and OIL due to the induced polarity when in contact with water and the nonpolar behavior under a zero net charge exposure. Detergents are large molecules with a polar and a nonpolar end, which makes them ideal for MIXING with both water and oil (see Figure P.126).

Figure P.126 Polarity of (a) detergent and (b) surface force of a polar medium.

Polarity of emf (electromotive force)

[electronics, general] The potential due to a surplus or deficiency of electron charges. For instance, a BATTERY has a positive and negative side, current flows per definition from positive to negative polarity.

Polarization

[general, nuclear, optics] Property of ELECTROMAGNETIC RADIATION, indicating the predominant angular direction of the electric field vector in a plane that is outlined by the direction of propagation coalescing with the normal to the plane, generally measured with respect to an arbitrary horizontal reference line. Certain animals can observe polarization, for instance the pygmy octopus, and it may communicate this way as well. The dung beetle and the field cricket for instance use the polarization of the LIGHT reflected by the MOON for navigation. Light reflecting from a surface will have a polarization direction that is outlined

by the orthogonal of the direction of propagation in the plane of the reflecting surface and the direction of propagation of the reflected WAVE (see [Figure P.127](#)).

Figure P.127 Dung beetle navigating the ball of dung for her breeding housing, at night under light as polarized when reflected by the Moon.

Polarization of light

[general] A transverse electromagnetic WAVE is plane polarized when the electric field oscillates in a single plane outlined by the direction of propagation, whereas a circularly polarized beam of LIGHT has the electric field perform a rotation around the axis of propagation in a circular pattern with DISTANCE traveled repeatedly per wavelength. Light generated by various sources, including the SUN and an incandescent lamp is unpolarized also referred to as NATURAL LIGHT (*also see MALUS' LAW*) (see [Figure P.128](#)).

Figure P.128 Sunlight by its nature is unpolarized. The reflection from the windshield of an automobile.

Polarization selective film

[chemical, general] Transparent sheet that facilitates the preferred transmission of LIGHT with a single angle of polarization. Iodine is linked to the POLYMER chain in a polyvinyl alcohol (PVA) sheet, which is stretched under raised temperature, forming aligned long chains of hydrocarbon molecules. The POLARIZATION angle lining up with the polymeric molecules will be transmitted. The concept was introduced in 1928 by EDWIN HERBERT LAND (1909–1991).

Polaroid™ film

[chemical, general] Light-sensitive POLYMER film constructed of NITROCELLULOSE (transparent) with embedded iodoquinine sulfate crystals invented by EDWIN HERBERT LAND (1909–1991) in 1928. Produced by the Polaroid Corporation® (with founder Edwin Land). Polaroid film produces a virtually instantaneous hard-copy photograph after a brief fixation process inside the CAMERA. The principle of the polaroid film was initially a polarizer, a sheet that allows only LIGHT with a single POLARIZATION direction to pass through. The initial synthetic polarizer sheet was clear polyvinyl alcohol that was heated and stretched. Subsequent DOPING with iodine formed a MICROSCOPIC wire structure that allowed only light with an electric field that lines up with the molecular chains of iodine to pass through. The first camera was the Polaroid Land Camera Model 95 loaded with the first Polaroid Land Film Type 40, which were first offered to the public in late 1948. The polaroid photographic film works as follows. Once the special light-sensitive film has been exposed the “PICTURE” rolls between two rollers that crack a pouch with chemicals that covers the exposed film and fixes the chemical processes so that they are no longer light sensitive. A short heating process fixes the chemicals to prevent any further chemical interactions. The ejected photograph was only in black and white for the first camera (using a single-layer silver compound), later converted to operate in COLOR by including three layers of RED, green, and blue emulsion that are all light activated, and the process takes approximately 45 s (see [Figure P.129](#)).

Figure P.129 Polaroid® camera.

Poles

[general, geophysics] Poles have various meanings, mainly indicating the fact that there are opposite properties involved with respect to location. Geographic poles of the EARTH indicate the connecting points on opposite sides of the world through which the axis of rotation passes, whereas the MAGNETIC poles are an indication of the beginning and end points on either side of the world where MAGNETIC FIELD lines connect; the two are not in identical locations. Moreover, the magnetic north and south poles DRIFT and have switched location several times in traceable history. The poles of a PERMANENT MAGNET are on opposite sides of the magnetic object, generally also referenced as NORTH and south poles. The MAGNETIC POLES were first described in 1267 by the French engineer PIERRE PELERIN DE MARICOURT (a.k.a. Peter Peregrine) (c. 1220–1270); however, MAGNETISM was known for centuries prior to that. Poles that are equal will repel, whereas opposite poles attract. The poles on a BATTERY are the respective positive and negative terminals (*also see* DIPOLE) (see [Figure P.130](#)).

Figure P.130 Compass indicating the orientation with respect to the Earth's magnetic poles.

P

Pollio, Marcus Vitruvius (c. 80 BC–c. 15 AD)

[general] Roman scientist, engineer, and architect. According to Pollio (actually known as Vitruvius), nature is the inspiration to architecture. Birds and squirrels built nests; likewise humans erect housing from NATURAL MATERIALS. The Greek initiated architectural orders that linked biology to man-made structures: Doric, Ionic, and Corinthian. The order described in this culminated in understanding the HUMAN BODY,

perceived as the greatest **ENGINEERING** feat. This symbiosis led Vitruvius Pollio to define the Vitruvian Man, which was adopted and later drawn by **LEONARDO DA VINCI** (1452–1519) (see [Figure P.131](#)).

Polonium ($^{84}_{209}\text{Po}$)

[atomic, nuclear] Radioactive, unstable “metallic” chemical **ELEMENT**, primarily found in uranium ores. Polonium was discovered by Marie (Many) **SKŁODOVSKA CURIE** (1867–1934) and her husband **PIERRE CURIE** (1859–1906) in 1898.

Polycrystalline solids

[general] Organized internal structure medium, often associated with metallic objects. A material that has no definite internal structure is amorphous, in contrast. Ordinary objects such as **METAL** spoons and metal cases are polycrystalline solids.

Polydimethylsiloxane (PDMS)

[biomedical, chemical] Chemical **ELASTOMER**, $\text{CH}_3[\text{Si}(\text{CH}_3)_2\text{O}]_n\text{Si}(\text{CH}_3)_3$. PDMS is a nontoxic semipermeable material (gas permeable) that is also transparent to **LIGHT** down to 300 nm. PDMS is often referred

to as an organosilicon, but is less expensive than silicon-based materials (“silicones”). Polydimethylsiloxane is an organic POLYMER that is used in many different applications, several in biomedical design; for instance contact lenses. Other consumer application is as a coating in shampoo, to make the hair slick and glossy.

Polymer

[biomedical, chemical] Synthetic compound, macro MOLECULE. The polymer matrix consists of repeated monomers (small molecular chains). In biomedical context, bone is considered a polymer, consisting of collagen and inorganic salts, comprised of carbonates and phosphates; alternatively, CELLULOSE is a polymer as well. Other biological polymers are proteins, starches, and latex. One of the most well-known and simple chemical polymers is polystyrene $(-\text{C}_6\text{H}_5)_n$ {MONOMER: C_6H_5 }, next to polyethylene $(-\text{CH}_2-\text{CH}_2)_n$. Other common consumer polymers are POLYDIMETHYLSILOXANE (PDMS), POLY(VINYLDENE) FLUORIDE (PVDF), and PVC (POLYVINYL CHLORIDE: $(-\text{CH}_2=\text{CHCl})_n$) (*also see* MONOMER) (see [Figure P.132](#)).

Figure P.132 Chemical structure of polystyrene polymer.

Polymethylmethacrylate (PMMA)

[biomedical, chemical, general] Transparent POLYMER, often used in place of GLASS, high strength making it shatterproof. Also known as acrylic glass; synthetic emulsion polymerization of methyl methacrylate, developed in 1928. Trade names include (but not limited to) Lucite®, Plexiglas®, and Perspex® (see [Figure P.133](#)).

Figure P.133 Plexiglas chairs.

Polypeptide

[biomedical, chemical] Amino-ACID monomers linked by peptide bonds to form a POLYMER structure. Often related to the formation of a polypeptide chain (see [Figure P.134](#)).

Figure P.134 Polypeptide in biological configuration.

Polytropic process

[astrophysics/astronomy, thermodynamics] Process that follows the CONTINUITY EQUATION for the linked properties for PRESSURE (P) and specific volume (V_s) as $PV_s^{n_p} = \text{Const}$, where n_p is the polytropic index; alternatively, with respect to ENTROPY (S) as a function of TEMPERATURE (T) it can be described as $T(dS/dT) = \text{Konstant}$. The polytropic index ($n_p = (c_p - \text{Konstant}) / (c_v - \text{Konstant})$), where c_p and c_v are the SPECIFIC HEAT under constant pressure or constant volume respectively, defines and characterizes the specifics of process. The concept of polytropic mechanism relies on the process path in the state diagram (i.e., P-V diagram; respectively T-S diagram), where several paths are possible and they intersect (polytropic path). Any closed system for GAS or VAPOR that involves HEAT TRANSFER and work can be described by a polytropic path. Polytropic process describes heat transfer, specifically associated with EXPANSION and contraction. In ASTROPHYSICS, this applies to fluids where the pressure is a function of the density, in solutions to the LANE-EMDEN EQUATION.

Polyvinyl chloride (PVC)

[biomedical, chemical, mechanics] Polymer chemical that has a wide range of applications, made by polymerization of vinyl chloride. PVC is a plastic that is a solid under normal conditions. PVC forms the basis for products such as pipes, vinyl siding, BLOOD bags, drink bottles, HEART bypass tubing, etc. It is the third most popular polymer after polyethylene and polypropylene. PVC poses significant health risks, primarily when exposed to incineration fumes and in dust form, specifically due to the high chlorine content. Chemicals known as dioxins are released during the manufacturing, or incineration of PVC.

Dioxins exposure can lead to problems in reproductive, respiratory (asthma), and developmental health as well as provide carcinogenic properties (see [Figure P.135](#)).

Figure P.135 Applications of polyvinyl chloride (PVC) in the formation of plumbing pipes.

Poly(vinylidene) fluoride (PVDF)

[acoustics, biomedical, chemical, mechanics] Thermoplastic polymer $-(C_2H_2F_2)_n-$. Versatile fluoropolymer used in biomedical applications to attract proteins (ADHESION) and in consumer applications for instance in the manufacturing of bottles and insulation on wiring. PVDF is a very strong material, as well as flexible, that can be electrically polarized and can withstand temperatures up to 149°C and down to -62°C and remain stable. Because of its electrical POLARIZATION (ferroelectric polymer, recognized in the 1970s), it has piezoelectric properties and is used in ULTRASOUND transducers and extremely small and thin pressure sensing devices. The PVDF TRANSDUCER can operate at frequencies above 15 MHz with low acoustic impedance and low residual electrical impedance. PVDF pressure transducers can be made in film format with minimal mass and size.

P

Pool, M. L.

[atomic, nuclear] (twentieth century) Scientist from the United States involved in the description of nuclear processes in 1935. One specific area of research by Pool was in monokinetic electron sources.

Population inversion

[general] Atomic or molecular artificial excitation with respect to GROUND STATE for the majority of excitable atoms/molecules. Population inversion is the essential and critical process in the mechanism of action for LIGHT amplification by STIMULATED EMISSION of radiation (LASER). The concept of population inversion was hypothesized by ALBERT EINSTEIN (1879–1955) in 1917. The Einstein theory of population inversion defines the phenomenological relations between external electric and/or MAGNETIC fields, interacting with a group of atoms. This interaction forms the elementary foundation when “laser” conditions can be accomplished. The primary condition to achieve the laser mechanism of action is the atomic/molecular population inversion. This situation is defined by the fact that a greater number of excited atoms are present in the laser medium than there are atoms in the ground state. In order to achieve this, the following conditions need to be analyzed. There will be a minimum amount of ENERGY required to raise the majority of atoms to the excited state. For this, the zeroth-order assumption is that all energy injected into the laser medium (the medium that has an ELECTRON DECAY process with an associated particular electromagnetic emission energy, i.e., single wavelength; in most cases, some lasers make use of a broad-band source, such as dye lasers)

provided to raise electrons to the excited state is 100% effective. In the case of 100% stimulation efficiency, only the electron energy lost due to light emission, resulting from stimulated emission in particular, will need to be replaced. The excited state is not necessarily a single energy band; most likely, the atomic structure will be composed of several bands that can be filled by supplying external energy excitation. Furthermore, those multiple excitation energy levels can be split further in modes. These excited energy modes will have their own associated characteristic lifetimes. The energy modes describing one single energy band can be referenced by the notation N_m , each individual mode with respective average lifetime τ_e . A relationship defining the MINIMUM ENERGY requirements for exciting (pumping) the laser medium to EXCITED STATES can be developed based on a range of assumptions. In zeroth-order approximation, the idealized situation of a system with simply two energy levels can be considered, consisting of the GROUND state energy and the excited state. The energy supplied as input for the excitation of a two-level system raises the ground state condition to an excited state in an acceptable first-order description for the process. The supplied energy is assumed to be provided by an external ELECTROMAGNETIC FIELD; however, also an ELECTRIC field alone or MAGNETIC FIELD or chemical reaction can satisfy the energy requirements. The electromagnetic input satisfies the Planck relationship $W = h\nu = h(c/\lambda)$. The additional assumption is that the supplied photon energy W matches exactly the difference in energy between the excited energy level E_2 and the ground level: E_1 : $E_2 - E_1 = h\nu_0 = h(c/\lambda_0)$. Because of the fact that this is a two-energy level system, the emissions will also only be composed of one single wavelength λ_0 or frequency $\nu_0 = \lambda_0/c$, with $c = 2.99792458 \times 10^8$ m/s the speed of light. The resulting boundary conditions for the “pumping” POWER (P) of the excitation source is hence: $P = N_m h c / \lambda_0 \tau_e$, where N_m is the necessary number of atoms to be promoted to an excited state. The rate of stimulated emission that fuels the process of laser emission is directly proportional to the absolute value of the difference between the number of atoms raised to the excited state N_2 , to the number of atoms sustaining the ground state N_1 , defined as $N_2 - N_1$. This difference between the excited state and the ground state (two [2] level system) is linearly proportional to the ratio of the average lifetime with respect to the PHOTON emission associated with the decay process τ_e , in reference to the average lifetime that belongs to the excited state τ_e , defined as $\Delta N = N_2 - N_1 = N_m \tau_e / \tau_e$. Although spontaneous emission is not a consideration, it will initially be the driving “force” for the decay process and is defined as $dN_2/dt = -A_{21}N_2$, where A_{21} is the PROBABILITY coefficient defining the spontaneous emission process, also known as the Einstein A_{21} coefficient, and has the dimension of time⁻¹. The light energy absorption process for stimulation will adhere to the same principles, outlined as $dN_1/dt = -R_{12}N_1 = -B_{12}U(\nu_0)N_1$, where B_{12} is defined as the absorption coefficient, and also has the dimension of time⁻¹. Similarly, the stimulated emission process can be described as $dN_2/dt = -R_{21}N_2 = -B_{21}U(\nu_0)N_2$, where B_{21} is defined as the stimulation probability, where B_{21} also has the dimension of time⁻¹ to remain consistent in the phenomenological description. The stimulation probability coefficient B_{21} depends on the energy-level transition only, and is hence a function of the particular ATOM used in the “laser medium,” thus providing the unique emission wavelength for each medium. The decay of the respective energy occupation populations N_1 and N_2 also depends on the radiance of the incident light, that is, the MAGNITUDE of the incident excitation photon FLUX, and additionally depends on the cross-sectional area representing the stimulation excited atom—target: $R_{21} = \sigma_{21}\Phi$, where R_{21} is the rate of stimulated emission, Φ is the incident electromagnetic flux, and σ_{21} represents the “target area” stimulated emission CROSS SECTION. In this process, the coefficients A_{12} , B_{21} , and B_{12} are referred to as the Einstein coefficients. In the population inversion process, there is a requirement for achieving a Metastable state. The metastable state is a function of the interaction of various ELEMENTS in the laser medium in the presence of other elements (i.e., the base medium matrix, doped with the excitable atoms used for the stimulated emission process), and one is required to account for the interaction of this atomic matrix with the energy structure of the neighboring atoms. This will be part of the second-order approach. Still back to the two-level system, the decay processes as a function of time (i.e., decay rate) for the energy levels N_1 and N_2 are defined by the following rate equations: $dN_2/dt = -A_{21}N_2 + B_{12}U(\nu_0)N_1 - B_{21}U(\nu_0)N_2$; $dN_1/dt = -dN_2/dt$. Once again employing the Planck’s black-body radiation equation (known as PLANCK’S LAW) for a BLACK BODY presumably at “virtual” temperature T , the emission of ELECTROMAGNETIC RADIATION with spectral profile $U(\nu)$ can be defined as $U(\nu_0)d\nu = (\nu^2/c^3)h\nu \{1/(\exp[h\nu/kT] - 1)\} d\nu = e'h\nu < n > d\nu$, where e' represents the EIGENVALUE for the RESONANCE energy density associated with the emitted photons, per photon, and n represents the average number of photons present in each respective resonance energy density.

The occupation of the respective energy levels N_1 and N_2 while operating under thermal equilibrium, satisfies the condition: $N_2/N_1 = (g_1/g_2) \exp[-h\nu/kT]$, where g_1 and g_2 are representing the respective RADIATION weight for the various energy levels. By definition, under thermal equilibrium the decay rate from level 1 is equal to the decay rate from level 2, and hence neither level will experience no decay what so ever:

$dN_1/dt = dN_2/dt = 0$. As a result of this particular boundary condition the following can be derived:

$-A_{21}N_2 + B_{12}U(\nu_0)N_1 = B_{21}U(\nu_0)N_2$. This can be rewritten as $[A_{21}N_2 + B_{21}U(\nu_0)]N_2 = B_{12}U(\nu_0)N_1$,

providing the electromagnetic field condition during population inversion:

$U(\nu_0) = A_{21}/[B_{12}(N_1/N_2) - B_{21}]$. Based on the conditions of thermal equilibrium between the two energy levels, and including the Planck black-body radiation, the Einstein coefficients can be shown to be correlated to each other as $B_{12}(g_1/g_2) = B_{21}$, and $(\nu^2/c^3)B_{21} = -A_{21} = U_e(\nu_0)B_{21}$. The condition $U_e(\nu_0) = (n^3/c^3)$ defines the spectral energy density for the situation of one (1) photon in each respective eigenvalue OSCILLATION, under the condition that the average number of photons present in each eigenvalue oscillation equates to only one single photon. This condition represent the fact that under an external field during stimulated emission this process equates to spontaneous emission, where only one single photon is allowed in each energy configuration. This condition is by definition satisfied based on the PAULI EXCLUSION PRINCIPLE as well as Schrödinger conditions and the de Broglie orbital constraints. The fact that in a real atomic energy configuration, the electron energy levels are split up due to the orbital constraints imposed by the BOHR ATOM model, the laser emission will not necessarily consist of a single wavelength, but rather be composed of spectral emission with a linewidth. This linewidth will be confined and defined by the choice in elements used to construct the LASER excitation medium. To summarize: the stimulated emission will dominate under population inversion $n > 1$, while for $n < 1$ the prevailing mechanism of light emission will be based on spontaneous emission. In order to harness the photons in the LASER medium, the laser medium has an optical construction known as a cavity that is confined by mirrors on either side, one side with slightly less than perfect reflectivity allowing laser light emission. The mirrors on opposite sides of the laser medium create an oscillator, or under specific boundary conditions a resonator (*also see LASER*).

Porphyrins

[biomedical, chemical] Sensitizer organic chemicals, which are neutral and nontoxic in their GROUND STATE but become chemically active when excited by a reagent medium, either chemical or energetic (e.g., photon energy). The porphyrin structure forms a macrocyclic structure, consisting of four pyrrole rings with joining molecular segments, primarily =CH-. Porphyrins consist of conjugate acids that are forming ligands that bind to metals (e.g., IRON in "heme"). The two most well-known porphyrins are chlorophyll (oxygen process in plant leaves) and heme as cofactor to the hemoglobin protein in BLOOD, used to acquire and loosely bind oxygen and carbon dioxide in the RESPIRATION system. One particular biomedical application is in PHOTODYNAMIC THERAPY to treat cancer through light-mediated chemical process that results in CELL death. Other chemical integrations are by means of for instance

pheoporphyrin, also known as a petroporphyrin. Pheoporphyrin is a geologic porphyrin found in coal, crude oil, sedimentary rocks, or oil shale (see [Figure P.136](#)).

Figure P.136 Heme porphyrin, cofactor, and integral part of the hemoglobin protein, used for the transport of oxygen by red blood cells.

Positive charge

[general] Net charge with value that has opposite sign of the charge of an electron; alternatively, with a charge that repels protons. Charge is quantized, on an atomic level by PROTON value and as a material based on the amount of missing electrons with respect to a neutral electric state. An object made from GLASS that is rubbed with silk or flannel will become positively charged, transferring electrons from the glass to the cloth. The existence of charges can be dated back to the rubbing of AMBER with fur, as described by PLATO (427–347 BC). The nomenclature of positive and NEGATIVE CHARGE (introducing the hypothesis that there are only two types of charges) was introduced by the scientist and statesman (founding father) from the United States BENJAMIN FRANKLIN (1706–1790), and was based on the presumed transfer of positive charge, later found to be a misinterpretation. Franklin's proposition was based on the observations by the scientist and astronomer from Great Britain STEPHEN GRAY (1666–1736) in 1730.

Positive displacement pump

[fluid dynamics] Machine that has as the mechanism of action for flow the reduction of volume of a chamber holding the liquid (see [Figure P.137](#)).

Figure P.137 Example of positive displacement pump: gear pump.

Positive ions

[atomic, nuclear] Atom or MOLECULE that is missing one or more electrons (see [Figure P.138](#)).

Figure P.138 (a) Positive ion interacting with negative ion, attraction and (b) lithium ion battery, popular rechargeable battery in most electronic portable devices.

Positive lens

[general] Lens that has a positive focal length and generally produces a magnified IMAGE with magnification greater than one (1) and produces a real image, providing the boundary conditions that are supporting the application. A positive lens is a converging LENS. Keep in mind that a converging lens with the object

placed at a DISTANCE closer than the FOCAL POINT will create a virtual image. The most well-known example of a positive lens is a loop (see Figure P.139).

Figure P.139 Example of positive lens, or loupe.

Positive rays

[atomic, nuclear] During the CATHODE ray experiments in 1886 by JOSEPH JOHN THOMSON (1856–1940), the observation was made that on the opposite side of the side of the tube where the ANODE is positioned and the CATHODE RAYS are fitting the GLASS window, other emissions were recorded that could be deflected by MAGNETIC fields, however, responding in opposite manner to the cathode rays. Thompson named them positive rays. The cathode ray tube from the late 1900s was preceded by the CROOKES TUBE, invented by the physicist and chemist from Great Britain SIR WILLIAM CROOKES (1832–1919) in 1870, resembling the modern neon-gas-discharge tube. This phenomenon was predated by observed and documented low-pressure discharges in a BAROMETER by the French astronomer JEAN PICARD (1620–1682) in 1675; however no conclusive evidence of the mechanism of action in both cases, or the values of the charges were involved.

Positron (β^+)

[astrophysics/astronomy, atomic, general, nuclear, quantum, thermodynamics] Positive counterpart of the electron, also sometimes referred to as the antielectron. The positron was predicted by the DIRAC EQUATION. The positron was discovered in 1932, and has an equivalent ENERGY of $E = mc^2 = 0.511$ MeV. The positron resulted from investigations into the COSMIC RAYS.

Positron annihilation

[atomic, biomedical, solid-state] Particle emitted by a radionucleotide ISOTOPE after a relatively short half-life. The positron will be emitted from a nucleotide during DECAY and subsequently annihilated after a relatively short lifetime (examples of RADIONUCLIDE half-life and inherent ENERGY are ^{18}F : 110 min, $E = 0.64$ MeV; ^{11}C : 22.4 min, $E = 0.96$ MeV; ^{15}O : 2.1 min, $E = 1.72$ MeV, where fluoride [^{18}F] is in a RADIOPHARMACEUTICAL: fludeoxyglucose [FDG]) with any of the many free electrons in the medium, specifically applied to biological media for imaging purposes in POSITRON EMISSION TOMOGRAPHY (PET). The annihilation process generally releases energy in excess of $E > 1.2$ MeV. The annihilation energy is released as two identical gamma (Γ) quanta with $E_\gamma = 511$ keV. These QUANTA are emitted in perfectly opposite directions. The energy balance for the positron annihilation process and the gamma pair production is described as $E_{\text{positron}} + E^{\text{kinetic}} + E_{\text{electron}} \geq 2E_\gamma$. The rest energy is derived from the difference in energy of the isotope and the annihilation product. In addition to the rest energy of the electron (E_{electron}) and the positron (E_{positron}) respectively, there can be positron or electron MOTION with respective kinetic energy E^{kinetic} . The nuclear

energy of the decay reaction follows from the quantum PHYSICS using the mass-energy equivalence, providing the REST MASS energy as $E = mc^2$, where m is the mass of the object and $c = 2.99792458 \times 10^8$ m/s the speed of LIGHT. The photon energy follows $E = h\nu$, where $h = 6.626068 \times 10^{-34}$ m² kg/s is PLANCK's CONSTANT and ν the frequency of the PHOTON. This yields $m_p c^2 + m_e c^2 = 2h\nu_\gamma$, where m_p is the mass of the positron and m_e the electron mass. Filling in the mass equivalent energy for each respective component yields $511 \text{ keV} + E_{\text{positron}}^{\text{kin}} + 511 \text{ keV} \geq 1.022 \text{ MeV}$. Only concurrent emission of two 511 keV gamma quanta is considered an indication of positron release (*also see ANNIHILATION*) (see [Figure P.140](#)).

Figure P.140 Positron annihilation and gamma pair emission.

Positron decay

[nuclear] See BETA DECAY.

Positron emission tomography (PET)

[atomic, biomedical, energy, general, imaging, nuclear, solid-state] Nuclear imaging technique that produces images by means of introduction of radioactive isotopes that will emit a positron at a relatively short half-life. This imaging technique offers the capabilities to determine METABOLIC ACTIVITY of living organisms through incorporation of a Trojan horse ISOTOPE in the cellular METABOLISM obtained through radioactive labeling. The short-lived positron-emitting radionuclide can be detected noninvasively for imaging purposes by specialized equipment. Specific crystals, for instance bismuth germanate (BGO), convert the high-energy gamma photons into lower ENERGY photons. The visible light photons can subsequently be collected by a semiconductor array, such as a CCD (charge-coupled device) ELEMENT. The CCD array converts the PHOTON energy into electrical data, registered and located in three-dimensional space by the tomograph ELECTRONICS. The RADIOPHARMACEUTICAL that is administered contains radioactively labeled chemical substances using constituents that are identical, or chemically equivalent, to naturally occurring ELEMENTS in the body. Radioactive labeling pertains to the fact that one ATOM in a MOLECULE is replaced by a radioactive equivalent, a radionuclide. Examples of radioisotopes used in PET imaging are, for instance, ^{11}C , ^{18}F , ^{13}N , and ^{15}O . All the short-lived radioisotopes used in PET scans DECAY by positron emission. Positrons (β^+) are positively charged electrons. Positrons hence have the same mass and rest energy as an electron. Positron emission isotopes are introduced in the BLOOD stream to finally be incorporated in the organ or tumor of interest. Imaging is made possible by the positron–electron annihilation process, which emits two gamma rays in opposite direction. A specially designed detection mechanism in a tomograph detecting the MAGNITUDE and detection sequence of the gamma photons and subsequently derives the isotope's location and concentration by interpolation, transforming the received SIGNAL in a three-dimensional IMAGE. The PET visualization provides the tools to identify normal and abnormal activity in living tissue. This is in contrast to X-RAY computed tomography (CT), which principally renders anatomical images. PET measures chemical

changes in the tissue that can be used to identify metabolic activity that is not consistent with normal healthy tissue. Analogously, MAGNETIC RESONANCE IMAGING (MRI) can also measure specific metabolic activity with the specific limitation to blood oxygenation consumption. In the annihilation process of the constituent as an example, fluoride is stabilized by removing a POSITIVE CHARGE from the NUCLEUS through the conversion shown in the chemical reaction: $^{18}_9\text{F} \rightarrow ^0_{+1}\text{e} + ^{18}_8\text{O}$. A special version of PET is SINGLE-PHOTON EMISSION COMPUTED TOMOGRAPHY (SPECT) (see [Figure P.141](#)).

Figure P.141 (a) Positron emission tomography equipment (PET) and (b) PET mechanism of action.

Positronium

[atomic, nuclear] Metastable, ISOLATED SYSTEM consisting of an electron and the antiparticle: positron, bound as a single hypothetical atomic structure, predicted in 1932, detected in the 1950s. The positronium energetically resembles a HYDROGEN ATOM; however, positronium does not have the positron as the NUCLEUS but as a partner in orbit. The positronium decays with the emission of two gamma QUANTA, each at 511 keV. Positronium is referred to as an “exotic” atom, which defines an altered atom in which one or more nuclides have been substituted by other type particles of the same charge in different ENERGY setting, not necessarily with same total energy (see [Figure P.142](#)).

Figure P.142 Positronium.

Potassium ($^{39}_{19}\text{K}$)

[biomedical, chemical] Mineral, ALKALI METAL. In biology, potassium is one of the essential constituents of cells and tissues. Potassium performs a critical function in most muscular functions and is in integral part of the MEMBRANE POTENTIAL.

Potassium chloride (KCl)

[biomedical, chemical] SALT. In many facets similar to SODIUM CHLORIDE (conventional table salt: NaCl).

Potential (V)

[general] Referring the electrical potential that is associated with a charge accumulation and the work requirements for transporting a charge to or from the charge cluster. The potential is the POTENTIAL ENERGY (PE) of a charge in the vicinity of a charge grouping per unit charge: $V = (\text{electrical} - \text{PE})/\text{charge}$. The potential energy results from the electric field emanating from the charge cluster. The potential difference between two locations is equal to the work performed moving a charge between the two locations, per value of the moving charge. The work (W) performed is the force on the charge multiplied by the DISTANCE traversed (d): $W = Fd$, where the FORCE (F) is the charge to be moved multiplied by the ELECTRIC FIELD (E), $F = dE$. The electric field is the potential over the distance $E = V/d$ (also see COULOMB LAW and VOLTAGE).

Potential barrier

[atomic, energy, quantum] A potential ENERGY discontinuity, or slope (BARRIER) expressed as electrical potential, that influences the SOLUTION to the SCHRÖDINGER EQUATION for the transportation of a charged particle (NUCLIDE, electron) through a charge cloud. The energy barrier can be the difference between GROUND STATE and excited state of an atomic electron. The PROBABILITY of crossing the barrier will be a function of the kinetic energy of the PARTICLE with respect to the barrier "height" (MAGNITUDE). The probability (P_{chance}) of passing a mass (m_0) with charge through the barrier (over a DISTANCE $x_2 - x_1$) can be written as proportional to the potential magnitude as $P_{\text{chance}} \approx e^{-\gamma_{\text{barrier}}}$, where $\gamma_{\text{barrier}} = (2/\hbar) \int_{x_1}^{x_2} \{2m_0 [V(x) - \text{KE}]\}^{1/2} dx$, with $\hbar = h/2\pi$ ($h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ PLANCK'S CONSTANT) (also see BARRIER PENETRATION and TUNNELING) (see Figure P.143).

Figure P.143 Potential barrier as part of a nuclear or atomic energy model. The probability of escape from the nucleus, respectively atom is proportional to the "height" of the barrier.

Potential difference

[biomedical, energy, general] The difference in potential between any two points in a circuit; the work required to carry a unit POSITIVE CHARGE from one point to another (*see* POTENTIAL or ELECTRICAL POTENTIAL as well as VOLTAGE) (*see* Figure P.144).

Figure P.144 Potential difference for a battery.

Potential energy (PE)

[general, mechanics, nuclear] The ENERGY that a body possesses by virtue of its location, external exposure, or mechanical attachments that it can potentially release in another form of energy (*Note: CONSERVATION OF ENERGY*). The potential to release energy can be made in reference to any point in space, where the work performed (W) to bring an object from one point to another point in space is the difference in potential energy between those two points: $W_{21} = PE_2 - PE_1$. Potential energy is expressed for location as $PE(x, y, z) = \rho V g s(x, y, z)$, where ρ is the density, V is the volume of the object, $\rho V = m$ is the mass of the object at rest, and $s(x, y, z)$ is the location of the object with respect to a point of reference, primarily height. One form of external exposure is a DIPOLE in an external MAGNETIC FIELD ($\vec{B}$), which has the potential of generating a TORQUE. The potential energy of the dipole (e.g., current loop) with MAGNETIC DIPOLE moment ($\vec{M}_{\text{current}} = NIA\vec{n}$) is expressed as $PE = -\vec{M}_{\text{current}} \cdot \vec{B}$, where I is the current in the loop, N the number of loops in the device carrying the current, A the area outlined by the loop, and $\vec{n}$ a unit vector in direction perpendicular to the plane of the loop, whose direction can be found by applying the right-hand rule. Additionally, for a spring, the mechanical attachment of an elastic device has the potential to release energy when the object is removed from the state of equilibrium, expressed as $PE = (1/2)ks^2$, where k is the spring constant and s is the displacement from equilibrium. Another form of potential energy is the potential of becoming engaged in a chemical reaction or nuclear degeneration (e.g., breaking down of isotopes). The potential energy stored in a SOLENOID with a magnetic field B may depend on the location within the solenoid and is frequently defined as energy density per unit VOLUME (V) as $PE/V = B^2/2\mu_0$, where μ_0 is the DIELECTRIC permeability of VACUUM. Similarly, the potential energy of a CAPACITOR with electric field E

between the plates is defined per unit volume as $PE/V = (1/2) \epsilon_0 E^2$, where ϵ_0 is the dielectric permittivity of vacuum (see Figure P.145).

Figure P.145 Example of potential energy resulting from elevation converted into hydroelectric energy.

Potential energy of a liquid surface

[biomedical, chemical, fluid dynamics, mechanics, thermodynamics] Molecules in the main body of a LIQUID are subject to thermal agitation and the internal forces on the molecules from neighboring molecules, and gravity will fluctuate but on average have zero balance, while the surface molecules are subject to an attractive force that maintains the molecules in the liquid. The molecules at the surface hence are considered to possess a potential ENERGY greater than the internal molecules of the liquid. The SURFACE TENSION provides the foundation for the SURFACE POTENTIAL ENERGY. The surface will continuously seek a condition of minimal potential energy, meaning that the surface will tend to shrink if allowed to assume minimum surface area with lower potential energy since the work needed to stretch the surface is counteracted by the potential energy. This also explains that a droplet in AIR will tend to take on a spherical shape, having the smallest area for any mass and volume. The surface potential is directly linked to the surface tension, however, with a correction for the MENISCUS curvature at the edge of the surface. The ANGLE of the surface with the WALL is represented by θ measured with respect to the wall above the liquid surface, giving the ratio of surface tension (σ_{surface}) to surface potential energy (γ_{surface}) as $\cos \theta = -\gamma_{\text{surface}}/\sigma_{\text{surface}}$ (see SURFACE TENSION).

Potential flow

[fluid dynamics] In FLUID DYNAMICS a “potential function” $\phi(x_1, x_2, t)$ can be defined that outlines the conformation to the CONSERVATION LAWS, with $\nabla \times \nabla \phi = 0$, while for IRROTATIONAL FLOW the average VELOCITY ($\vec{v}$) is defined by $\vec{v} = \nabla \phi$. Lines of $\phi = \text{Constant}$ describe the velocity field, also called potential lines of flow. The velocity profile is defined with respect to orientation (x_1, x_2) as $d\phi = u' dx_1 + v' dx_2$, where $u' = \partial \phi / \partial x_1$ and $v' = \partial \phi / \partial x_2$. For the potential flow, it yields $dx_2/dx_1 = -u'/v'$, representing the potential lines that are by definition perpendicular to the streamlines. The streamlines are defined by the STREAM FUNCTION ψ , $u' = \partial \phi / \partial x_1 = \partial \psi / \partial x_2$. Note that irrotational flow is best defined by ϕ , while incompressible flow adheres to ψ ; for incompressible, irrotational flow both parameters apply. With the potential function, the flow definition reduces to one parameter instead of three velocity components: (u', v', w') . The VELOCITY POTENTIAL satisfies the LAPLACE EQUATION. The potential function for flow can be used to rewrite the Bernoulli equation as $\rho[(\partial/\partial t)\nabla \phi + (1/2)(\nabla \phi)^2] + \nabla P + \rho g \nabla x_3$, with P the pressure, ρ the local density, and g the GRAVITATIONAL ACCELERATION. The CIRCULATION (Γ_{circ}) for a free VORTEX in irrotational flow is described as $\Gamma_{\text{circ}} = \oint_C \vec{\omega}(\vec{r}, t) d\vec{r} = \oint_C \nabla \times \vec{v}(\vec{r}, t) d\vec{r} = \oint_C \nabla \phi(\vec{r}, t) d\vec{r}$, where $\vec{\omega}$ represents the vorticity (also see CAUCHY–RIEMANN EQUATIONS).

Potential head

[fluid dynamics] The head in FLUID DYNAMICS relates to the height of a LIQUID column; combining this with applied pressure, the potential head becomes the pressure head plus the elevation head. Expressed in ENERGY, the potential head is the potential energy per unit weight of the FLUID. The pressure head is the PRESSURE (P) per DENSITY (ρ): $P/\rho g$; the elevation head is height of the column y . For dynamic systems, the total head is the kinetic head plus the potential head, where the kinetic head (KH) is $KH = v^2/2g$, with v the flow velocity and g the GRAVITATIONAL ACCELERATION (see Figure P.146).

Expressed in energy the potential head is the potential energy per unit weight of the fluid. The pressure head is the pressure (P) per density (ρ): $\frac{P}{\rho g}$, respectively, the elevation head is height of the column: y . For dynamic systems the total head is the kinetic head plus the potential head, where the kinetic head (KH) is $KH = \frac{v^2}{2g}$, where v is the flow velocity and g the gravitational acceleration

Figure P.146 (a,b) Potential head.

Potential well

[atomic, chemical, computational, nuclear, quantum, thermodynamics] In atomic PHYSICS, the ENERGY function for a nucleon in motion ("orbit") can be described by the SCHRÖDINGER equation, specifically in spherical coordinates only the radial part (r) remains: $-(\hbar^2/2m_0)(d^2u/dr^2) + \{[\ell(\ell+1)\hbar^2/2m_0r^2] + V(r)\} = Eu$, where $V(r)$ represents the potential that confines the nucleon, ℓ the ORBITAL QUANTUM NUMBER, u the (radial-) wavefunction, a polynomial function, $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ PLANCK'S CONSTANT, m_0 the nucleon mass, and E the total energy of the process (kinetic and potential energy). Under the boundary conditions, u will be a finite polynomial when $r \rightarrow \infty$. For an INFINITE SQUARE WELL with radius R , the

potential function becomes $V(r) = 0$ for $r < R$; $V(r) = \infty$ for $r = R$. Alternatively, for a harmonic oscillator potential, the well is defined as $V(r) = (1/2)m_0\omega_0 r^2$ for $r < R$, where ω_0 is the oscillator angular frequency. More realistic cases are $V(r) = -V_0$ for $r \leq R$ and $V(r) = 0$ for $r > R$; alternatively, $V(r) = -V_0 + br + cr^2$ for $r \leq R$, a “rounded” or parabolic well (see Figure P.147).

For: $\ell = 0, 1, 2, 3, 4, 5$
The spectroscopic letters are assigned as follows:

Figure P.147 (a,b) Potential well.

Potentiometer

[general] Variable, continuously adjustable RESISTOR. Generally, the potentiometer has three poles, between two the RESISTANCE increases (using the “center” connection as a reference) as the dial is turned clockwise; alternatively, switching the outer connectors makes the resistance decrease with increasing ANGLE (see Figure P.148).

Figure P.148 Potentiometer.

Pound (lb)

[general] Unit of mass in the English unit system. One pound in SI UNITS equals 453.592 g. Most units in the system of measurements used in the United States are based on the British Imperial Units; however, in 1824 the British units were adjusted and there are now differences with the American units; for instance, the imperial gallon equals in SI units 4.54609 liters, whereas the US Gallon is 3.785411 liters.

Pound, Robert Vivian (1919–2010)

[atomic, imaging, nuclear] Scientist from Canada who was instrumental in the discovery and development of nuclear magnetic resonance imaging (MRI), while at Harvard University. The MAGNETIC RESONANCE work coincided with the independent work of the Swiss scientist FELIX BLOCH (1905–1983). He gained

additional fame with his experimental verification of general relativity concepts in the POUND–REBKA EXPERIMENT, in collaboration with Glen Anderson Rebka, Jr. (1931–) in 1959 (see [Figure P.149](#)).

Figure P.149 Robert Vivian Pound (1919–2010). (Courtesy of Harvard University; Cambridge, MA. Image reference: UAV 605.270.5p, Box 7, Pound, Robert V., Harvard University Archives.)

Pound–Rebka experiment

[relativistic] Experimental verification of the special relativistic gravitational REDSHIFT and general relativistic blueshift under DOPPLER circumstances. The experiment performed by ROBERT VIVIAN POUND (1919–2010) and his student Glen Anderson Rebka, Jr. (1931–2015) in 1959 at Harvard University, Boston, MA, USA, combined the special relativistic redshift with the general relativistic blueshift. The special relativity ($\square$) Doppler shift is given by $\Delta v_{d,s} = \sqrt{\{1 + (v^2 \cos^2 \theta / c^2) / [1 - (v^2 / c^2)]\}} v_0$, where θ is the ANGLE between the relative velocity and the direction of MOTION of the source, v the relative velocity between the source and the observer, and c the speed of LIGHT. The blueshift predicted by general relativity resulting from gravitational influences ($\square_g$) is defined as $\Delta v_{d,g} = \sqrt{\{[1 - [2GM / (R + b) c^2]] / [1 - (2GM / R c^2)]\}} v_0$ $R \gg b$ $(MGb / R^2 c^2) v_0$, with G the gravitational constant, R the radius of curvature, and M the gravitational mass (i.e., Earth's mass). In superposition, this yields for the observation made by the detector: $\Delta v_{d,s,g} / v_0 = \sqrt{\{[1 + (v^2 \cos^2 \theta / c^2)] / [1 - (v^2 / c^2)]\}} \{1 - [2GM / (R + b) c^2] / [1 - (2GM / R c^2)]\}$. At the time, measuring the influence of the gravitational attraction from the top of the Harvard Jefferson building with a height of $b = 21.6$ m, resulting in a [measured] Doppler shift of $\Delta v_{d,s,g} / v_0 = 2.46 \times 10^{-15}$ for a 14 400 eV gamma ray produced by the Fe^{57} ISOTOPE, quite extraordinary.

Poussin, Baron Charles-Jean Étienne Gustave Nicolas de la Vallée (1866–1962)

[computational] Mathematician and physicist from Belgium. Charles de la Vallée Poussin is known for proving the Prime number theorem in 1896. Other work included the study of approximation theory (see [Figure P.150](#)).

Figure P.150 Baron Charles-Jean Étienne Gustave Nicolas de la Vallée Poussin (1866–1962).

Powell, Cecil Frank (1903–1969)

[atomic, nuclear] Scientist and physicist from Great Britain. Cecil Powell developed an innovative method using a photographic film to elucidate SUBATOMIC PARTICLES. The COSMIC RAYS at high altitude appeared to interact with the nuclei within the emulsion of the film. Discoverer of the π -meson, also known as the ; in 1946 (see [Figure P.151](#)).

Figure P.151 Cecil Frank Powell (1903–1969).

Power (P)

[general, nuclear, thermodynamics] The TIME (t) rate of doing work ($W = \vec{F} \cdot \vec{d}$, the force F applied to move an object over a DISTANCE d): $P = dW/dt$; alternatively, the time rate of expenditure of ENERGY: $P = dE/dt$; units Watt (W). Also the force applied to a moving object in the direction of MOTION to maintain a constant velocity: $P = \vec{F} \cdot \vec{v}$, for instance to overcome resistive forces such as friction (sliding or rolling). In electrical applications, the power is the consumed or generated power from the CURRENT (I) and voltage (V), combined with OHM'S LAW with respect to RESISTANCE R (or more generally impedance Z), also referred to as apparent power $P = VI = V^2/Z = I^2Z$. Some examples of power equivalencies: $1(\text{BTU}/s) = 1054 \text{ W}$, $1 \text{ horsepower (HP)} = 745.7 \text{ W}$, $1(\text{gallon of oil/minute}) = 2.5 \text{ MW}$, and $1(\text{J/s}) = 1 \text{ W}$. The average power exerted by the human HEART can be estimated based on the contractile force, expressed as the ventricular PRESSURE (P) times the area of the aortic VALVE (A) multiplied by the flow velocity (v): $P = PAv$, which per beat is approximately 1.2 W . The power produced by the SUN (as a "NUCLEAR REACTOR") is approximately $4 \times 10^{26} \text{ W}$. The power produced by a waterwheel is on the order of $1\text{--}75 \text{ kW}$; the output depends on the head difference, flow rate, and the efficiency that is a function of the design and how well the water FLOW is "captured" to generate the torque. The power output of an undershot wheel is a function of the total area of the paddles that are exposed to flow (A), the flow velocity (v_{flow}), and the conversion efficiency (η_{conv}), expressed as $P = 100\eta_{\text{conv}}Av^3$; while for an "overshot" or breast shot wheel, the power results from the flow (Q) times the "bucket" size (volume V [i.e., the weight]; the head of the wheel [h_{head}]) as $P = 4\eta_{\text{conv}}QVh_{\text{head}}$. The efficiency is the result of the way water is captured as well as the electric GENERATOR attached or the mechanical gear to produce the work. The work can for instance be making paper, cutting wood, or lifting water (see Figure P.152).

Figure P.152 Waterwheel performing work and generating the power to perform other work.

Power cycle

[thermodynamics] Cyclic change of state in a thermodynamic system, such as a Carnot machine, Sterling cycle, OTTO CYCLE, Rankin cycle, DIESEL CYCLE, JOULE-BRAYTON CYCLE, cooling (refrigeration), or heating cycle, transforming ENERGY at a high- or low-temperature source to work. An additional power cycle is the LINDE-HAMPSON LIQUEFACTION CYCLE.

Power factor

[general] Real power consumption in an electrical circuit based on the PHASE shift (θ) between the current and the voltage resulting from the complex impedance: $P = VI \cos \theta$, where $\cos \theta$ represents the power factor for the alternating current circuit configuration. Note that $\cos \theta = 1$ for a purely resistive system.

Power law

[computational] Mathematical expression that has one parameter as a function of another parameter expressed to the order of a fixed or variable mathematical expression; for instance, in the most rudimentary form, $f(x) = ax^n$. The expression is the result of a causal dependency that influences the output by a certain MAGNITUDE or function. WIEN'S DISPLACEMENT LAW is one of many examples.

Power method

[computational] Computational mechanism of deriving eigenvalues for the solutions to a function. One interpretation is that the eigenvalues are the matrix ELEMENTS of a polynomial EXPANSION. The base matrix is used to derive the subsequent terms in an iteration method, substituting the last derived output to derive the subsequent term.

Power number ($N_p = c_{Np} (P_w/\omega_N^3 \rho L^5)$)

[energy, fluid dynamics, mechanics] Dimensionless number indicating the ratio of the net DRAG FORCE to the net INERTIAL FORCE pertaining to rotational systems, where $P_w = \Delta W/\Delta t$ (i.e., rate of change in WORK) is the POWER consumed or produced by the device, ω_N the rotational rate of change, c_{Np} a dimensional constant, ρ DENSITY, and L characteristic length. The Power number relates to MOMENTUM transfer in for instance agitators, pumps, and fans as well as power consumption.

Power spectrum

[acoustics, computational, optics] The ENERGY distribution per frequency range ("bin"), converting the SIGNAL distribution in a discrete format. This has particular value for the situation where there are limited frequencies, for example, harmonics only. The power spectrum generally can be derived by taking the FOURIER TRANSFORM. Note that the Fourier transform of a product is the convolution of the respective Fourier transforms and that the Fourier transform of a convolution is the product of the respective Fourier transforms.

Poynting, John Henry (1852–1914)

[electromagnetism, energy, general] Physicist from England. John Poynting was the theoretical resource behind the development of the general description of CONSERVATION OF ELECTROMAGNETIC ENERGY, in particular the flow of ELECTROMAGNETIC ENERGY and hence he was the eponym of the POYNTING VECTOR (see [Figure P.153](#)).

Figure P.153 John Henry Poynting (1852–1914).

Poynting correction

[thermodynamics] Expression used in the fugacity of LIQUIDS as a correction to LIQUID–VAPOR EQUILIBRIUM of a non-IDEAL GAS. The expression for the FUGACITY itself is $\pi_f(T, P) = \pi_f(T, P_0) \exp[\mu_f(T, P) - \mu_f(T, P_0)/RT]$, a slight deviation from the IDEAL GAS LAW: $PV = nRT$. The exponential term rewrites as $\exp[\mu_f(T, P) - \mu_f(T, P_0)/RT] = \exp\left\{\left(v_f/RT\right)[P_f(T, P) - P_{\text{sat}}(T)]\right\} \cong 1 + (v_f/RT)[P_f(T) - P_{\text{sat}}(T)]$, which is known as the Poynting correction. For ordinary media, the ideal gas law will be adhered to and the Poynting correction is close to unity, with the inherent condition that the fugacity is independent of the pressure and approximately equates $\pi_f(T, P) \cong P_{\text{sat}}(T)$.

Poynting vector ($\vec{S}$)

[atomic, electromagnetism, general] Vector indicating the direction and rate of passage through a unit area in the direction of propagation of the transport of ELECTROMAGNETIC ENERGY from the combined effects of an electric field ($\vec{E}$) and a MAGNETIC FIELD ($\vec{B}$), defined as $\vec{S} = (1/\mu_0)(\vec{E} \times \vec{B}) = \vec{E} \times \vec{H}$ (where $\vec{B}$ is the magnetic field measured in Tesla, and H is the MAGNETIC field expressed in N/mA), units: W/m^2 , where $\vec{S} = (\sqrt{\epsilon_0\mu_0}/4\pi)(\vec{E} \times \vec{B})$ is the Poynting vector and $c = \sqrt{\epsilon_0\mu_0}$ is the speed of LIGHT.

Praetorius, Michael (original name: Michael Schultheiß) (1571–1621)

[acoustics, mechanics] Composer and scientist from Germany. Praetorius used a particular musical analysis and organization and provided a rhythm “template” for sacred music in particular (cantus and hymns) (see [Figure P.154](#)).

Figure P.154 Michael Praetorius (1571–1621).

Prandtl, Ludwig (1875–1953)

[astrophysics, computational, fluid dynamics, thermodynamics] German mathematician and physicist that pioneered the development of a rigorous mathematical description of flow patterns and the influence of forces. He introduced the BOUNDARY LAYER in 1905. The boundary layer consists of a thin section of the flowing medium where the interaction with an object or other medium is expressed. The pioneering work by Archimedes (287–212 BC) only provided basics on statics for fluids. Additional anecdotal details of flow were presented by LEONARDO DA VINCI (1452–1519) by graphical interpretation. While LEONARD EULER (1707–1783) described the flow of a medium conceptualized as a CONTINUUM of small fluid ELEMENTS, the boundary effects were still not well defined in his days. The work of DANIEL BERNOULLI (1700–1782) was

more generalized that of Euler. The internal FRICTION with respect to fluid FLOW was introduced by CLAUDE-LOUIS NAVIER (1785–1836) in 1822 and later refined (presumably independently) by GEORGE STOKES (1819–1903) in 1845 to culminate in the Navier–Stokes equations for flow. He hypothesized that FLUID elements (Euler’s concept) directly in contact with a surface, which was moving at a different velocity, would experience attraction, and hence friction. The boundary layer is very different for a pure LIQUID in comparison to a colloid solutions (e.g., BLOOD), where the boundary effects will extend for the particulates. The body (or liquid) inside a flowing fluid will experience pressure on its surface and shear tangentially to the surface. The boundary layer will display a velocity profile that is dependent on the DISTANCE to the surface. Elaborating on Prandtl’s concept, PAUL RICHARD HEINRICH BLASIUS (1883–1970) expanded on the boundary layer problem in 1908 illustrating the separation of a boundary layer. Prandtl postulated a hypothesis on MIXING length for fluid-mechanic layers in 1925. The MIXING LENGTH (ℓ_m) is the distance along the shear layer at a surface, it takes for the fluid to reach the time average of an assumed sinusoidal velocity fluctuation starting out from turbulent, expressed as a function of the eddy viscosity η_T , the turbulent velocity (u_T), the velocity profile as a function of the STREAM FUNCTION (ψ) expressed as $U_y = \partial\psi/\partial y$; respectively $U_x = -\partial\psi/\partial x$, defined by $u_T \sim \ell_m |\partial U_y / \partial y| = \ell_m |\partial^2 \psi / \partial y^2|$ as a function of the distance to WALL ($\mathcal{Y}$). Far from the wall, the mixing length can also be approximated as a function of the von Kármán constant (κ_K) as $\ell_m = \kappa_K \mathcal{Y}$; however, this does not apply to the viscous sublayer. The known values for the mixing length for certain flow conditions are for instance for a regular emission JET: $\ell_m = 0.09 \ell_s$, where ℓ_s is the half-width of the shear layer; and for a circular jet: $\ell_m = 0.075 \ell_s$ (see Figure P.155).

Figure P.155 Ludwig Prandtl (1875–1953).

Prandtl number ($Pr = (\eta/\alpha_{dif}) = c_p \eta / \kappa$)

[fluid dynamics] Dimensionless number expressing the ratio of the DIFFUSIVITY of momentum to thermal DIFFUSION, where η the KINEMATIC VISCOSITY, α the THERMAL DIFFUSIVITY, c_p the HEAT CAPACITY, and κ the THERMAL CONDUCTIVITY. This number shows the relation between HEAT TRANSFER and MECHANICS in both free and forced convection.

Prandtl–Meyer expansion

[fluid dynamics] Mathematical approach for SUPERSONIC FLOW, describing the ISENTROPIC expansion of a MACH WAVE through a series of Mach waves, where the CENTRAL wave portion is referred to as the Prandtl–Meyer expansion. The EXPANSION is divergent. This phenomenon is in particular related to the propagation

of a supersonic flow through a shock. Under these conditions, for normal flow the flow velocity normal to the shock is expected to increase; however, this will violate the SECOND LAW OF THERMODYNAMICS.

Prandtl–Meyer function

[fluid dynamics] Mathematical approach for SUPERSONIC FLOW, describing the ISENTROPIC expansion of a MACH WAVE through a series of Mach waves, where the central WAVE portion is referred to as the PRANDTL–MEYER EXPANSION. The Prandtl–Meyer function describes the flow expansion (fan type) as a function of the changing MACH NUMBER (Ma) as a function of ANGLE with the line of propagation: $dw/w = (dMa/Ma) + (dv_s/v_s)$, where $w = \sqrt{u_x^2 + u_y^2}$, u_x and u_y respectively the orthogonal flow-velocity components, $v_s = (\partial P / \partial \rho)_s$ the speed of sound, P the pressure, and ρ the local density. Expressed as a function of angle (Θ_{PM}) as the Prandtl–Meyer function: $\Theta_{PM}(Ma) = \sqrt{[(\gamma_b + 1)/(\gamma_b - 1)]} \tan^{-1} \left(\sqrt{[(\gamma_b + 1)/(\gamma_b - 1)][Ma^2 - 1]} \right) - \tan^{-1} \left(\sqrt{Ma^2 - 1} \right)$, where $\gamma_b = c_p/c_v$ is the ratio of SPECIFIC HEAT at constant pressure (c_p) to specific heat at constant volume (c_v). Generally, the parameter Θ_{PM} is listed in tabular form for the specific flow conditions.

Precession

[atomic, biomedical, mechanics, nuclear, quantum] Rotation of the axis of SPIN around a reference axis. The precession of the Earth's rotational axis is slow with a period of approximately 26 000 years. The rotation of the EARTH around the SUN provides the seasonal changes. A spinning top will “wobble” with its axis of rotation around the perfect vertical axis, normal to the gravitational plane. The angular velocity of the precession (ω_p) is the result of the MOMENT OF INERTIA (I_m), and the spinning ANGULAR VELOCITY (ω) around the object's axis of symmetry is expressed as $\omega_p = (d\phi/dt) = mgr/I_m\omega$, with r the DISTANCE from the intersect of the axis of rotation with the vertical reference axis (frame of reference; i.e., the pivot point) to the center of mass of the object in rotation with mass m , g the GRAVITATIONAL ACCELERATION, and ϕ is the ANGLE of rotation. Precession is used to give a GYROSCOPE a very stable frequency (*also see* LARMOR PRECESSION) (see Figure P.156).

Figure P.156 The process of precession.

Pressure (P)

[biomedical, fluid dynamics, general, material, mechanics] Force (F) per unit area (A), expressed in all directions with equal MAGNITUDE: $P = \lim_{\Delta A \rightarrow 0} (\Delta F / \Delta A)$. Pressure has no direction and is hence a SCALAR quantity. The pressure of a LIQUID column with density ρ is directly proportional to the height (h) of the column above the point of interest, in addition to the pressure above the liquid from the GAS column (e.g., ATMOSPHERIC PRESSURE): $P = \rho gh + P_0$, where g is the GRAVITATIONAL ACCELERATION. Pressure can be used

to transfer force by means of changing the area as used in hydraulic systems. At the “critical pressure” in the PHASE DIAGRAM, the liquid phase and the VAPOR phase become identical. The units for pressure are PASCAL (Pa); colloquial use is ATMOSPHERE, or PSI (pounds per square inch) (see [Figure P.157](#)).

Figure P.157 Phase diagram including the influence of pressure on the physical conditions and state of a medium: (a) medium that has a lower density at temperature below the liquid–solid phase transition, for instance water, and (b) medium with decreasing density with decreasing temperature.

Pressure coefficient ($P_t = (P - P_\infty) / (1/2)\rho_\infty v_\infty^2$)

[astrophysics, fluid dynamics] Dimensionless number describing the ratio of the relative PRESSURES throughout a FLOW field to the KINETIC ENERGY density, also referred to as INERTIAL FORCES. In a FLUID FLOW field, every point will have a unique respective pressure coefficient. In the definition, the following parameters are used: P the pressure, P_∞ the pressure in the main body/volume of the fluid medium, ρ_∞ the bulk DENSITY, and v_∞ the VELOCITY of flow in the main part of the medium or main free flow. The pressure coefficient applies to flow over an AIRFOIL as well as BOUNDARY LAYER effects in fluid flow and RHEOLOGY.

Pressure cooker

[general] Device that is sealed in order to increase the PRESSURE (P) with respect to the ambient pressure in the closed VOLUME (V) with the direct consequence of an increase in temperature (T) of the boiling point of the LIQUID in the container based on the Boyle–Gay–Lussac law: $PV/T = \text{Constant}$. The concept of the pressure cooker was invented by DENIS PAPIN (1647–1712) in the late 1600s. For food, the chemical denaturation process increases by approximation over every 10°C, while the modern pressure cooker is designed to operate at approximately 121°C; the processing time is dramatically reduced. Alternatively, when living at high elevation, for instance in Denver, CO, USA, mile-high city (elevation approx. 1600 m), the cooking temperature is dramatically reduced under regular conditions, requiring longer cooking times. The autoclave is another example used for sterilization of medical equipment based on this principle (see [Figure P.158](#)).

Figure P.158 Pressure cooker.

Prévost, Pierre (1751–1839)

[general, nuclear, thermodynamics] Scientist and clergyman from Switzerland with a minor interest in law. Primarily known for his contributions on heat (thermodynamics) and MAGNETISM (see [Figure P.159](#)).

Figure P.159 Pierre Prévost (1751–1839). (Courtesy of *Journal Officiel Illustré De L'Exposition Nationale Suisse* Genève 1896.)

Prévost theory of heat exchange

[atomic, nuclear] Matter at constant temperature is in perfect equilibrium, proposed by PIERRE PRÉVOST (1751–1839) in 1791.

Priestley, Joseph (1733–1804)

[chemistry] English chemist and theologian attributed with the discovery of the colorless and reactive GAS oxygen (O_2 ; although it was named by the French chemist ANTOINE LAURENT LAVOISIER [1734–1794]). Priestley's breakthrough observation was that AIR was not a single substance but a mixture of elementary components,

that is, gasses, as published in 1774. Additionally, Priestley invented several items such as the rubber eraser and carbonated water (see [Figure P.160](#)).

Figure P.160 Joseph Priestley (1733–1804) in 1794. (Courtesy of Ellen Sharples [1769–1849]. Scan of a print. Original at the National Portrait Gallery, London, England.)

Primary colors

[general] Based on human perception the following three colors can be used to make up in access of 10 million colors as defined by the base colors RED, green, and blue (RGB), as outlined by the CIE CHROMATICITY diagram. The RGB mechanism is for instance applied to monitors as well as digital cameras. The documented first observation of the eye's response to three colors was by THOMAS YOUNG (1773–1829) in the early 1800s (see [Figure P.161](#)).

Figure P.161 Color chart as defined by the CIE 1931 (Commission internationale de l'éclairage; "International Commission on Illumination") with primary colors defining the corners of the map.

Primary cosmic ray particles

[atomic, nuclear] Various SUBATOMIC PARTICLES reach the Earth's ATMOSPHERE from outer space, ranging from protons (~89%) to helium nuclei (10% of total), up to uranium nuclei (1% heavy nuclei). In the upper atmosphere, these particles will collide and generate reactions, primarily generating pions.

Primary electron

[solid-state] The electron ejected from an ATOM by an initial ionizing event, as caused by a PHOTON or BETA PARTICLE.

Principal moments

[atomic, mechanics, solid-state] The MOMENT OF INERTIA associated with a rigid molecule. The MOLECULE has three principal moments, which follow from the diagonalization of the moment of inertia matrix:

$$I = \begin{bmatrix} \sum_i m_i (y_i^2 + z_i^2) & -\sum_i m_i x_i y_i & -\sum_i m_i x_i z_i \\ -\sum_i m_i y_i x_i & \sum_i m_i (x_i^2 + z_i^2) & -\sum_i m_i y_i z_i \\ -\sum_i m_i z_i x_i & -\sum_i m_i z_i y_i & \sum_i m_i (x_i^2 + y_i^2) \end{bmatrix} = C \begin{bmatrix} I_A & 0 & 0 \\ 0 & I_B & 0 \\ 0 & 0 & I_C \end{bmatrix},$$

where in case all three moments are equal the molecule is referred to as a spherical rotor (e.g., CH₄); in case only two are equal the molecule is a symmetric rotor (e.g., CH₃CL); and if all three are different the molecule is an asymmetric rotor (e.g., H₂O).

Principal plane

[mechanics] The plane to which the stress in the direction of the normal is at extreme (maximal/minimal).

Principal quantum number

[atomic, nuclear] QUANTUM NUMBER defining the binding states of electrons: n . For the ENERGY states of the electron with mass m_e and charge $e = 1.60217657 \times 10^{-19} \text{C}$, this provides for a NUCLEUS with cumulative proton charge Z : $E_n = -m_e e^4 Z^2 / 8 \epsilon_0^2 h^2 n^2$, with $\epsilon_0 = 8.85419 \times 10^{-12} \text{C}^2/\text{Nm}^2$ the permittivity of free space and $h = 6.62606957 \times 10^{-34} \text{m}^2 \text{kg/s}$ PLANCK'S CONSTANT. In the Bohr model, this yields $E_n = -(13.6/n^2) \text{eV}$ for each level, $n = 1, 2, 3, \dots$. Note that in some cases, the "REDUCED MASS" need to be used: $m' = m_e M / (m_e + M)$, where M is the total mass of the protons.

Principal stress

[biomedical, mechanics] Stress in the PRINCIPAL PLANE.

Principia of Newton

[general] Published in 1687 by SIR ISAAC NEWTON (1642–1727) on the laws of MOTION as well as the wave-particle duality of light: the first law is the LAW OF INERTIA; the SECOND LAW is the force law; and the third is the law of reciprocity. The WAVE characteristic of LIGHT was not readily accepted for almost 150 years, until resurrected by THOMAS YOUNG (1773–1829) and AUGUSTIN FRESNEL (1788–1827).

Principle of complementarity

[general] Fundamental principle that applies to quantum-mechanical phenomena, specifically with respect to the BOHR ATOMIC MODEL as described by Niels Henrik David Bohr (1885–1962) in 1913. The principle of

complementarity states that in quantum-mechanical phenomena the outcome of experimental observations is directly correlated to the instruments used to analyze the mechanism of action, which is related to the Schrödinger “cat” (both alive and dead) as well as the double slit that appears to describe that a single PHOTON can be in two place simultaneously. Based on the “complementarity,” the basic mathematical formalisms of QUANTUM MECHANICS were developed autonomously by both WERNER HEISENBERG (1901–1976) and ERWIN SCHRÖDINGER (1887–1961) in 1926. The consequence of the principle of complementarity was the Copenhagen interpretation of quantum mechanics.

Principle of conservation of mass

[fluid dynamics] See CONSERVATION OF MASS.

Principle of corresponding states

[fluid dynamics, solid-state] Theorem introduced by JOHANNES DIEDERIK VAN DER WAALS (1837–1923) in 1873 concerning the similar (identical) behavior of all fluids at the scaled parameters for temperature ($T_s = T/T_c$), volume ($V_s = (V/V_c)$), and pressure ($P_s = P/P_c$) with the same compressibility factor $Z_c = P_c V_c / n_c k_b T_c$, which is taken at the critical point ($\square_c$), where n_c is the number of particles (molecules/atoms) and $k_b = 1.3806488 \times 10^{-23} \text{ m}^2 \text{ kg/s}^2 \text{ K}$ is the Boltzmann coefficient. The fluids can be considered to act under the same deviation (adjustment/offset) from the IDEAL GAS LAW, as if they are ideal gasses.

Principle of highest entropy

[thermodynamics] A system that is in stable equilibrium will have a higher entropy than any other system state with the same constituent and ENERGY parameters. Alternatively, this configuration will have the lowest energy.

Principle of least action

[general, mechanics] In follow-up on NEWTONIAN MECHANICS, the concepts of equation of MOTION can be derived from perturbations to stationary situations. The least action principle considers the path of an object with mass m and potential ENERGY $U(\vec{r})$ that leads from beginning to end as a function of time (t), instead of the start and end points, assigning a SCALAR that defines the action as a function of location ($\vec{r}$): $S[\vec{r}(t)] = \int_{t_1}^{t_2} [(1/2)m\dot{\vec{r}}^2 - U(\vec{r})]$, where the path holds an extremum of the “action” performed, $\dot{\vec{r}} = d\vec{r}/dt$.

Principle of lowest energy

[thermodynamics] A system that is in stable equilibrium will have the lowest ENERGY in comparison to the identical system in any other state.

Principle of relativity

[general] Relativity is subdivided into general relativity and special relativity; see the respective descriptions for additional details. The concepts of relativity were introduced by ALBERT EINSTEIN (1879–1955) in 1905. Based on Newtonian physics, as introduced by SIR ISAAC NEWTON (1642–1727), GRAVITY was constant, but with new knowledge adjustment had to be made. The traditional gravitational potential (ϕ_G) linked by the Poisson equation to gravity was $\nabla^2 \phi_G = \nabla \cdot \nabla \phi_G = [(\partial^2 / \partial x^2) + (\partial^2 / \partial y^2) + (\partial^2 / \partial z^2)] \phi_G = 4\pi G \rho$, where ∇^2 is the Laplace operator, G is the gravitational constant, and ρ is the density of MATTER, which was changed to include a time-dependent aspect as the d'Alembertian operator ($\square_{d'A}$): $\square_{d'A} \phi_G = \left\{ \left[(1/c^2)(\partial^2 / \partial t^2) \right] + \nabla^2 \right\} \phi_G = 4\pi G \rho$, where $c = 2.99792458 \times 10^8 \text{ m/s}$ is the speed of LIGHT. The first postulate by Albert Einstein with respect to relativity is that all laws of PHYSICS are valid and identical for observers moving in uniform motion, even though they may be in separate reference frames. The second postulate states that the speed of light, in free space, will be constant and independent of the MOTION of the source. Relativity is split between the fields of “classical physics” and “modern physics.” Relativistic

concepts are the result of Einstein's postulate that gravity is curved, in both space and time, as part of general relativity under classical physics, while the postulates of Einstein are part of modern physics.

Prism

[optics] Transparent body with specifically two surfaces at an ANGLE. The medium of the optical body will have an index of refraction different from the ambient medium, generating refraction at both surfaces, resulting in an angular deviation from the ray incident with an angle to the normal on the first surface, incident in the plane outlined by the normal and the axis of the plane normal to the line mating the adjoining plane (see Figure P.162).

Figure P.162 Prism- and color-based refraction (i.e., wavelength).

Probability

[atomic, computational, nuclear, thermodynamics] Branch in mathematical analysis that studies the likelihood of the occurrence of an event. The probability is the specific outcome divided by the total number of events. The probability ranges from 0 to 1, or respectively 0% to 100% likelihood. Specifically, with respect to other events in a probability distribution. The probability is often weighed against a null hypothesis, as proposed in 1931. The null hypothesis is the definition that the event is related to the most-likely phenomenon, at “zero change,” in contrast to the “alternate hypothesis” that everything is different. The most well-known probability is for a coin toss; “heads–tails,” with 50% probability for “heads,” provided a large enough number of tosses are performed. Probability is frequently used to prove or disprove a hypothesis, when the number of occurrences yields a fit less than a certain “ p -value,” chosen based on preferences: $p < 0.05$, $p < 0.01$, $p < 0.005$; the smaller the p -value the better the argument that the alternate to the null hypothesis is *rejected*; hence the event is true in comparison to a standard. The p -value is an indication of the significance of obtaining a test value with statistical MAGNITUDE at least as high in comparison as actually observed, under the assumption that the null hypothesis is true. Alternatively, the p -value is an indication of getting a different answer than the null hypothesis; hence a small p -value means low likelihood and null hypothesis stands correct. Probability can be distributed over opportunities. Several probability distributions are available from a mathematical foundation: POISSON DISTRIBUTION, NORMAL DISTRIBUTION, GAUSSIAN DISTRIBUTION, multinormal distribution, iniform distribution, delta function, bionomial distribution, Bernoulli distribution, gamma distribution, Student's t -distribution, and several more. Note that the “normal” distribution is not the most likely probability distribution for every phenomenon; the name does

not represent the causality. The choice of distribution has to do with the sample size, the phenomenon, and the representation of “outliers” (failed events) (*also see* **BAYESIAN ANALYSIS**) (see [Figure P.163](#)).

Figure P.163 Concept of probability.

Probability, theory of

[computational, mechanics]: fundamental concept of **PHYSICS** in the description of the opportunities and chances for an event or **ENERGY** configuration the form and the path the process will follow based on the available options of energy distribution as initially described by **BLAISE PASCAL** (1623–1662) and **PIERRE DE FERMAT** (1601–1665). Theoretical analysis pertaining to random phenomena. The nondeterministic events in physics and engineering that are either discrete, unique in occurrence, or have a pattern of evolution that does not follow a path that can be defined by strict conditions (i.e., **STOCHASTIC PROCESS**). The probability theory dates back to the teachings of **PIERRE DE FERMAT** (1601–1665), **BLAISE PASCAL** (1623–1662), and **PIERRE-SIMON MARQUIS DE LAPLACE** (1749–1827) with further refinements by for instance **ALEKSANDR MIKHAILOVICH LYAPUNOV** (1857–1918). The formulation of these events has its primary foundation in statistical methods. In biomedical aspects, this relates to **BAYES' THEOREM**. The other side of **PROBABILITY** is in **QUANTUM MECHANICS** and **HEISENBERG'S UNCERTAINTY PRINCIPLE**. Examples of stochastic processes are **BROWNIAN MOTION**, thermal collisions, and the **DOUBLE-SLIT EXPERIMENT**. An additional feature of a wave representation of an object in **MOTION** provides a mechanism of outlining the probability of an objects location, in particular the location of an electron. This provides a concept known as the probability flux. The probability **FLUX** is associated with solutions to the **SCHRÖDINGER WAVE EQUATION**, outlining the momentum associated with the eigenvalues of the solutions that can be used to define a “particle density” (*also see* **PROBABILITY**).

Projectile

[general, mechanics] Object moving in two or three dimensions. **GALILEO GALILEI** (1564–1642) was one of the first documented scientists that recognized that the projectile **MOTION** can be segregated in two independent motions: horizontal and vertical. The horizontal motion is the result of the applied force,

whereas the vertical motion is defined by gravitational interaction. A ballistic projectile is an object that is launched to target something (see [Figure P.164](#)).

Figure P.164 Ballistic projectile.

Prompt neutron

[atomic, nuclear] During NUCLEAR FISSION, in excess of 99% of NEUTRON are emitted within a “brief” delay (10^{-12} s), with respect to the FISSION event and are referred to as prompt neutrons. Several neutron may be emitted as long as minutes later and these are called delayed neutrons. However small the fraction of delayed to prompt neutron may be, the delayed neutrons form an essential control mechanism for the nuclear reaction.

Propeller

[fluid dynamics] Circular symmetric three-dimensional mechanical design with discrete sections that are twisted to perform a specific fluid dynamic function during rotation around the central axis. Blades on a propeller will convert rotational MOTION into thrust, either moving the object the propeller is attached to or making the propeller rotate under an applied flow to for instance generate ELECTRICITY. Propellers are found on airplanes and boats in particular for PROPULSION, and on wind turbines for generating electrical power. The THRUST (T_b) provided by a propeller is a function of the ANGLE of the blade (ϕ) and the LIFT of the blade from the plane of attachment (α) as well as the ENERGY from the torque on the blade as a function of location (L) and shear energy over the blades (w , at widest segment): $T_b = dL \cos(\phi + \alpha) - dw \sin(\phi + \alpha)$, with associated TORQUE (τ_b), as a function of the radius to the axis (r), approached by discrete incremental steps over the radial DISTANCE along the length of the propeller: $\tau_b = r \{ dL \cos(\phi + \alpha) - dw \sin(\phi + \alpha) \}$, where $dL = (1/2)\rho |\vec{v}_e|^2 c^* C_\ell dr$ (with ρ the fluid density, $\vec{v}_e$ the exit flow velocity, c^* a fractional factor (representative of the performance efficacy), C_ℓ the surface) and $dw = (1/2)\rho v_e^2 c^* C_d dr$ (with C_d the surface area carved out by the rotating propeller). Propeller efficiency (η_{propel_p}) with respect to propulsion is the ratio of the kinetic energy of the flow ($P_{\text{flow}} = \dot{m}[(u_e^2/2) - (u_0^2/2)]$), where $\dot{m} = \partial m / \partial t$, $u_e = \vec{v}_e \cdot \vec{n}$ the normal flow velocity through the propeller, and u_0 the background FLOW velocity (i.e., flight velocity), and with respect to the propulsive power ($P_{\text{propel}_p} = \text{thrust} \times \text{flight velocity}$): $\eta_{\text{propel}_p} = 2[1 + (u_e/u_0)]^{-1}$, which is equivalent to the efficiency of a jet engine. Alternatively, the FLUID dynamic efficiency for a GENERATOR is rather complex, depending on the fluid FLOW (e.g., water, AIR, combustion), and only the power (P_{turbine}) and efficiency (η_{turbine}) for a wind TURBINE is provided. The power of a wind turbine in approximation is a function of the rotor swept area (A_{swept}), the density of the air (ρ), the wind velocity (v_w), the generator efficiency ($\eta_{\text{generator}}$), the gear transfer efficiency (η_{gear}), as well as a general coefficient of performance (c_{perf}): $P_{\text{turbine}} = 0.5\rho A_{\text{swept}}\eta_{\text{gear}}\eta_{\text{generator}}\eta_{\text{perf}}v_w^3$; the efficiency is now: $\eta_{\text{generate}_p} = (P_{\text{out}}/P_{\text{turbine}}) = (VI/0.5\rho A_{\text{swept}}\eta_{\text{gear}}\eta_{\text{generator}}\eta_{\text{perf}}v_w^3)$, where P_{out} is the electrical output power, based

on CURRENT (I) and voltage (V), which requires corrections for PHASE losses (the generator is a multiphase generator, ideally all need to be in phase), specifically when multiple generators are connected together. Wind turbines generally do not effectively generate electricity at wind velocity below 8 km/h (see [Figure P.165](#)).

Figure P.165 Range of propellers used for the generation of electricity. Specialty propeller designs for wind turbines. (Courtesy of Helix Wind.)

Propulsion

[general, mechanics, thermodynamics] Push forward, mechanism of THRUST that makes an object move, operationally based on NEWTON'S THIRD LAW. Propulsion is specifically associated with JET engines, whereas PROPELLER engines provide propulsion as well. The force is exerted in several directions, while a remaining net force exerted on one surface that will result in a MOTION of that surface with radial forces canceling out and the force in the direction opposite to the surface in motion discarded. Thrust is a force (F), specifically the change in momentum ($p = mv$, where m is the mass and v the velocity; note that the combustion mass changes over time as well: $\dot{m} = dm/dt = \rho v A$ as a function of DENSITY (ρ), and cross-sectional area (A)) over time (t): $F = (dp/dt)$. The propulsion of a jet engine can be expressed as $F_T = \dot{m}_e v_e - \dot{m}_0 v_0 + (P_e - P_0) A_e$, where the respective subscripts denote the exit ($\square_e$) and ambient ($\square_0$) conditions, and the PRESSURE (P) plays a role as well. The rocket engines for the space shuttle for instance produce 1.8 MN thrust. The propulsion from a propeller engine with propeller area (A_{prop}) can be expressed as $F_T = 2\rho A_{\text{prop}} (v_\infty + v) v$, where v_∞ is the fluid velocity, v the velocity "induced" to the medium (e.g., increase in AIR flow, water flow), and ρ the FLUID density (also see PROPELLER) (see [Figure P.166](#)).

Figure P.166 Water propulsion.

Proton

[atomic, nuclear] Nuclear particle (BARYON, HADRON) with a positive ELECTRIC CHARGE equal numerically to the charge of the electron and having a mass of $m = 1.673 \times 10^{-27} \text{ kg} = 1.007575 \text{ mu}$ and charge $q = +1.60217657 \times 10^{-19} \text{ C}$. FERMION with SPIN of one half unit: $s = (1/2)\hbar = (1/2)(h/2\pi)$ ($h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ PLANCK'S CONSTANT). The PROTON is composed of three quarks, two quarks in the “up” direction and one in the “down” orientation (classification: uud). Theoretically, a proton can DECAY with emission of a PION or positron; however, experimentally to date there is no evidence that a proton will decay, and the lifetime of a proton has been established at 10^{31} years.

Prout, William (1785–1850)

[atomic, biomedical, nuclear, thermodynamics] Physician, chemist, and scientist from Great Britain. William Prout proposed that based on the current knowledge of the periodic table all ELEMENTS were composed of constituents resembling the HYDROGEN ATOM, called “protyle” by William Prout, although never observed by him. His concepts of nuclear structure predate the Bohr model and verified detection of specific particles by almost one hundred years. Additionally, Prout made statements about the biological system, such as the METABOLIC ACTIVITY, that could not be verified at the time but hold great value for current biological knowledge. The unit of NUCLEAR BINDING ENERGY was named after him, the Prout, which is $(1/2)$ binding energy of the DEUTERON = 185.5 keV. He also made several contributions to the theoretical description of HEAT TRANSFER. Based on William Prout's rudimentary but essential contributions to the understanding of the nuclear construction, the discovery of the PROTON was named in his honor by ERNEST RUTHERFORD (1871–1937) during its discovery in 1920 (see [Figure P.167](#)).

Figure P.167 William Prout (1785–1850).

Prout's hypothesis

[nuclear] Proposition that all chemical ELEMENTS are constructed with base building blocks resembling the helium ATOM, referred to as “protyle.” Suggested by WILLIAM PROUT (1785–1850) in 1815. Using the protyle as the building block for ISOTOPE, atomic mass description is accurate within 1%.

Pseudo plastics

[biomedical, fluid dynamics] **SHEAR-THINNING FLUID**, FLUID that decreases in **SHEAR FORCE** with increasing flow velocity. The associated viscous phenomena also decrease with a reduction in viscosity per se, in contrast with a **NEWTONIAN FLUID** or dilatant fluid (see [Figure P.168](#)).

Alterations in viscosity: (i) Non-newtonian fluids, (ii) apparent viscosity, and (iii) the Fahraeus–Lindqvist effect.

(a)

(b)

Figure P.168 (a) Shear-thinning and (b) slurry, liquid manure.

Psychrometry

[thermodynamics] **Energetic study of MOIST AIR**. The mixture of air and water VAPOR in the Earth's **ATMOSPHERE** may generally be considered as an **IDEAL GAS**, not accounting for foggy conditions. Also referred to as **hydrometry**. The graphic outline of the relationship between **RELATIVE HUMIDITY**, specific humidity, molar fraction, and total mass of water vapor is represented by a psychrometric chart, also known as **MOLLIER CHART** (see **MOLLIER CHART**).

Ptolemaeus, Claudius (approximately 90–168 AD)

[astrophysics/astronomy, geophysics] Astronomer, mathematician, and geophysicist from Greece. Author of a comprehensive work on all the information available in his time on the SOLAR SYSTEM and astronomical phenomena: *Μεγάλη Σύνταξις* (i.e., summary), mostly based on the work of HIPPARCHUS (190–125 BC). He is also known for his detailed tabulation of trigonometrical data with greater detail and more elaborate incremental steps than most current mathematical handbooks (also **PTOLEMY**) (see [Figure P.169](#)).

Figure P.169 Ptolemy (approximately 90–168 AD), rendering produced in the early sixteenth century.

Ptolemy (approximately 90–168 AD)

[general, optics] Scientist from Greece. Ptolemy described the ANGLE of incidence and refraction for water and made attempts to relate them mathematically (also **CLAUDIUS PTOLEMAEUS**).

p-type doping

[atomic, electronics, general] Intrinsic SEMICONDUCTORS that have had impurities introduced are considered to be doped, impurities consisting of foreign atoms into a crystal lattice structure. The crystal lattice structure provides the conduction and ENERGY platform for a stable structure. Certain semiconductors have VALENCE electrons that can easily be moved to the CONDUCTION BAND, sometimes spontaneously under slightly elevated temperatures. The ultimate release of the conduction electron (electron deficiency) creates a “hole” in the semiconductor lattice that can travel as if it were a POSITIVE CHARGE, hence the nomenclature *p*-type doping; positive. Introduction of an impurity with three valence electrons generally results in the formation of a “hole” in the lattice. The lattice may for instance consist of germanium or silicon. The FERMÍ LEVEL for intrinsic semiconductor materials is generally in the middle between the VALENCE BAND and the conduction bands in the energy level diagram. For the *p*-TYPE SEMICONDUCTOR, the valence band will have “hole energy” whereas the conduction band comprises “electron energy.” Joining a *p*-type semiconductor with an *n*-TYPE SEMICONDUCTOR creates a PN-JUNCTION that can be influenced to modulate electron transmission between the two semiconductor materials, creating on an elementary level a DIODE. The addition of more *n*-type and/

or *p*-type junctions will form transistors and more complex integrated circuit designs (*also see N-TYPE, DIODE, and TRANSISTOR*) (see [Figure P.170](#)).

Figure P.170 *p*-type doping, semiconductor energy configuration.

p-type semiconductor

[electronics, general] Semiconductor material with an electron deficiency, permanently imbedded “holes” (*see P-DOPING*) (see [Figure P.171](#)).

Figure P.171 Silicon oxide crystal design as the basis for certain semiconductor platforms.

Pulley

[general, mechanics] System of wheels with v-shape or u-shape channel along the outside track of the wheel to fit a belt or rope (chain) to run over the outside circumference. The pulley acts as a force multiplier depending

on the number of up–down loops used for hoisting a mass upwards, or alternatively for a horizontal force and direction. Hanging a mass on the pulley and attaching a rope to a location above the pulley will require half the force applied to raise the object when applying tension on the free distal end of the rope. This is due to the fact that both ends of the rope have equal tension, combinedly yielding the gravitational force on the object; thus the free end only has half the tension, requiring half the force (see [Figure P.172](#)).

Figure P.172 Pulley.

Pulmonary system

[biomedical, fluid dynamics] Biological system consisting of the lungs and vasculature, providing RESPIRATION function. The GAS exchange in the lungs between AIR and BLOOD is based on HENRY'S LAW that states that the gas volume, and therefore the concentration ($[Gas]$) dissolved in a LIQUID is directly proportional to its partial PRESSURE (P), defined as $[Gas] = K_{sol}P$, where K_{sol} is a solubility constant. The thin alveolar and pulmonary CAPILLARY walls provide a minimal BARRIER, allowing for swift DIFFUSION of oxygen and carbon dioxide, yielding a rapid equilibrium for the respective partial pressures of the constituents. This equilibration diffusion is described by Fick's law, relating the rate of diffusion to the concentration gradient as well as surface area for gas exchange, while being inversely related to the thickness of the WALL of the exchange surface; alveolar membrane. Pulmonary CIRCULATION is the flow from the HEART to the lungs and back. One specific biomedical complication in FLUID DYNAMICS is a pulmonary EMBOLISM, a blockage due to plaque or blood clot that reduces the flow to zero. At this point, the local VENTILATION/PERFUSION ratio becomes large, while reducing it for the

“healthy” part of the lung. The remaining functional perfused segment of the lungs will result in large arterial to alveolar P_{O_2} , difference with an associated increase in PHYSIOLOGICAL DEAD SPACE (see [Figure P.173](#)).

Figure P.173 Pulmonary system.

Pulsar

[astrophysics/astronomy, general] Collapsing spinning STAR, “end of life,” resulting in increased density with decreasing angular momentum and associated increasing ANGULAR VELOCITY (ω) (resembling a figure skater performing a pirouette, pulling in the arms and legs). The rotational ENERGY of the pulsar follows from Newtonian physics as $E_{\text{rot}} \sim (1/2)MR^2\omega^2$, with R the radius of the pulsar and M its mass. One known pulsar in the CRAB NEBULA has a mass equivalent to our SUN, however only at a 25 km diameter due to the collapse. The Crab Nebula pulsar (“Crab pulsar”) rotates at $\omega = 60\pi \text{ rad/s}$, emitting X-RAY and gamma radiation at pulsating intervals. The pulsar emission is generally erratic and irregular in both frequency and MAGNITUDE, as well as spectral profile, but will generally resemble the angular period (see [Figure P.174](#)).

Figure P.174 Supernova remnant and pulsar wind nebula in the constellation of Taurus.

Pulsatile flow

[biomedical, fluid dynamics] Many systems have a periodic flow pattern based on the mechanism of action of the device providing the ENERGY for the flow. In biological applications, the pulsatile flow is provided by the beating HEART. The flow process in biological systems is very complex due to the COMPLIANCE of the system (vascular dilation/stretch), and downstream RESISTANCE that can be influenced by mechanical and hormonal functions (e.g., muscle contraction and adrenaline). Other mechanical pulsatile systems are piston pumps, rotary pumps, and for instance windmills with a paddle system operating with ANGULAR VELOCITY ($\omega = v2\pi$, where v represent the alternation frequency). The flow in mechanical systems can be analyzed using the (time-dependent) Navier–Stokes equation ($\rho(\partial u/\partial t) = -(\partial P/\partial z) + \mu\{(\partial^2 u/\partial t^2) + [(1/r)(\partial u/\partial r)]\}$, with the boundary condition ($\partial u/\partial z = 0$) assuming that the FLUID is incompressible (constant density ρ); the tubes are rigid with constant radius r , for LAMINAR FLOW at flow velocity u , driven by an applied PRESSURE (P) gradient as a function of the axial direction z . Developing the pressure gradient in a series will prove to be beneficial: $(\partial P/\partial z) = \sum_{n=1}^N C_n e^{in\omega t}$, disregarding the steady-state background flow that can be incorporated in various ways (e.g., $n = 0$) and the velocity is directly in line with the pressure fluctuations (*also see BLOOD FLOW*) (see [Figure P.175](#)).

Figure P.175 Pulsatile flow used during a tooth-cleaning procedure.

Pulse oximeter

[biomedical, optical] Optical sensor device used to determine the partial oxygen SATURATION of BLOOD circulating in a biological system. The pulse oximeter relies on two aspects: PULSATILE FLOW and differential absorption between oxyhemoglobin (HbO_2) and deoxyhemoglobin (hemoglobin Hb). Hemoglobin has a much higher absorption in RED, at approximately 660 nm, while oxygenated hemoglobin has a slightly higher attenuation in the INFRARED (IR) 940–960 nm bandwidth. The pulsating nature brings fresh oxygenated blood in the tissue region on a period interval matching the heartbeat. Comparing the attenuation at two or more wavelengths as a function of time allows the oxygenated portion to be segregated out and yields the expression for the percentile oxygen saturation (SpO_2) as
$$\text{SpO}_2 = \left\{ \mu_{a\lambda=\text{red}}(\text{Hb}) / [\mu_{a\lambda=\text{red}}(\text{Hb}) - \mu_{a\lambda=\text{red}}(\text{HbO}_2)] \right\} - \left\{ \mu_{a\lambda=\text{IR}} / [\mu_{a\lambda=\text{red}}(\text{Hb}) - \mu_{a\lambda=\text{red}}(\text{HbO}_2)] \right\}^*$$

$\left[\ln(\psi_{\lambda=\text{red}}) - \ln(\psi'_{\lambda=\text{red}}) \right] / \left[\ln(\psi_{\lambda=\text{IR}}) - \ln(\psi'_{\lambda=\text{IR}}) \right] \}$, where μ_a represent the spectral attenuation coefficient and ψ the radiance of the LIGHT at the respective wavelength (see Figure P.176).

Figure P.176 Optical background in pulse oximetry for the determination of the oxygen saturation of blood.

Pump

[fluid dynamics, thermodynamics] Mechanical device designed to move fluids. The fluids can include PARTICLE solutions (slurry, waste). Many different mechanism apply to the pumping action, ranging from a diaphragm, pistons to screws and also peristaltic action. The peristaltic action is known for the transport of emulsions in the esophagus and intestinal tract for mammals. The lobe pump is generally used for transporting cooling FLUID in automobiles. Old-fashioned plunger-operated hand pumps for water displacement are found to very effective and require no other ENERGY source than MUSCLE action. Another low-energy pump operating on a similar mechanism is the bobbing oil-pump found at OIL wells. A pump that requires no power to operate, except to initially get the process started is the siphon. The siphon requires a negative pressure to fill the tube, and gravitational pull will maintain flow as long as the distal end of the siphon (hose) is lower than the entry point and the entry point remains submerged at all times to prevent AIR from entering into the system, hence defeating the VACUUM. Pumps satisfy the Bernoulli and Navier–Stokes equations (see Figure P.177).

(a)

(b)

Figure P.177 (a) Water pump and (b) oil pump.

Purcell, Edward Mills (1912–1997)

[astrophysics/astronomy, atomic, biomedical, nuclear] Physicist from the United States who won a Nobel Prize for his discovery of the nuclear MAGNETIC RESONANCE effects of certain LIQUID and solid media in 1952. Additional efforts of Purcell were in RADIOASTRONOMY and microwave technology (see [Figure P.178](#)).

Figure P.178 Edward Mills Purcell (1912–1997).

p-wave

[biomedical] In the ELECTROCARDIOGRAM (ECG) of the HEART the DEPOLARIZATION wavefront starts in the atrium that excites the ventricle, where the QRS-complex is representative of the depolarization of the ventricular cardiac MUSCLE. The *p*-wave is the depolarization of the atrium resulting from the SA-node trigger (natural PACEMAKER; sinus node or sino-atrial node [sino-auricular]; located on the right atrium) (see [Figure P.179](#)).

Figure P.179 Atrial *p*-wave and its relevance in the electrocardiogram (ECG). The QRS-complex is the main segment for ventricular electrical cell-membrane depolarization and repolarization activity.

Pyroelectricity

[acoustics, atomic, electromagnetism, fluid dynamics, general, mechanics, quantum, solid-state, thermodynamics] Electrical potential generated by heating certain crystalline structures. The thermal effect results in a LATTICE structure reorganization that produces a permanent ELECTRIC DIPOLE structure that aligns, forming a polarized structure.

Pythagoras (c. 570–c. 495 BC)

[computational, general] Pythagoras of Samos was a scientist and mathematician from Greece. Supposedly, a great deal of his mathematical knowledge was influenced by Babylonian scientists during his captivity in what is now known as the Persian Empire. Apart from the introduction of the PYTHAGOREAN THEOREM, Pythagoras is known for his work on astronomy and discovered the OCTAVE aspect of VIBRATION frequencies for string instruments. Pythagoras and his followers also introduced the principle that the SUN was the center of our planetary system based on certain mathematical principles of PLANETARY MOTION as observed with rudimentary devices. However, this concept was not generally accepted until the late fifteenth century, NICOLAUS COPERNICUS (1473–1543) (see [Figure P.180](#)).

Figure P.180 Artist impression of what Pythagoras (c. 570–c. 495 BC) may have looked like.

Pythagorean theorem

[computational, general] Geometric analysis of a triangle linking the lengths of the three edges with respect to the longest edge (c) as to the remaining edges (respectively a and b): $c = \sqrt{a^2 + b^2}$. The Pythagorean theorem was defined by the Greek mathematician PYTHAGORAS (approx. 570–490 BC).

PZT

[acoustics, biomedical, electromagnetism, general, mechanics] Specifically the material: lead (Pb)-zirconate (Zr)-titanate (Ti) (PZT; $\text{Pb}[\text{Zr}_m\text{Ti}_{1-m}]\text{O}_3$, where $0 \leq m \leq 1$), a synthetic ceramic material used as an acoustic TRANSDUCER. PZT in its indigenous state exhibits no piezoelectric properties of its own. When the PZT material is heated past the Curie point in temperature, the ceramic material can have the

internal dipoles to be aligned by means of an externally applied electric field. The PZT is in this manner used to create ACOUSTIC WAVES resulting from an alternating electric field, usually in the MHz range for ULTRASOUND imaging. The speed of sound in the artificial ceramic PZT material is approximately 4000 m/s. The operating frequency of the medium is determined by the combined conditions of the speed of sound and the thickness of the medium. The half wavelength of the SOUND pulse will need to match the dimension of the ceramic, the thickness; for a 5 MHz (i.e., center frequency) pulse the wavelength is $\lambda = v_{\text{sound}}/\nu = 4000/5 \times 10^6 = 0.8 \text{ mm}$, which yields for the thickness 0.4 mm. The RESONANCE FREQUENCY of the PZT block is achieved from a short block-WAVE voltage spike in the μs range (see PIEZOELECTRIC TRANSDUCER).

Q Equation

[atomic, chemical, nuclear] Reaction quotient, describing the transposition of states and ENERGY configurations. The reaction quotient for a chemical process is defined as the ratio of the concentration of products to the concentration of reactants, for instance in a reaction with ingredients $A; B; C; D$ at relative quantities $a; b; c; d$ in reaction $aA + bB \rightleftharpoons cC + dD$, with respective (molar-) concentrations $[A]; [B]; [C]; [D]$, proceeding as $a[A] + b[B] \rightleftharpoons c[C] + d[D]$, which yields the reaction quotient $Q_c = C^c D^d / A^a B^b$. This can provide the change in Gibbs free energy (ΔG) as ($\Delta G = \Delta G^0 + RT \ln Q_c$), at temperature T with $R = 8.3144621(75) \text{ J/kmol}$ the GAS constant, applied to SOLUTION (see Figure Q.1).

Figure Q.1 Diagram representing the implication of the Q equation. Reaction example: $\text{CO}(g) + \text{H}_2\text{O}(g) \rightleftharpoons \text{CO}_2(g) + \text{H}_2(g)$ (g: gas) in molar quantities: $\text{CO} = 1.00 \text{ mol}$, $\text{H}_2\text{O} = 1.00 \text{ mol}$; $\text{CO}_2 = 2.00 \text{ mol}$, $\text{H}_2 = 2.00 \text{ mol}$, with $Q_c = [\text{CO}_2][\text{H}_2] / [\text{CO}][\text{H}_2\text{O}] = 2 \times 2 / 1 \times 1 = 4$, while the (gas-) equilibrium constant is defined in relative quantities as follows: 1 unit CO reacts with 1 unit H_2O yielding 1 unit CO_2 and 1 unit H_2 with equilibrium constant $K = (\text{CO}_2)(\text{H}_2) / (\text{CO})(\text{H}_2\text{O}) = 1 \times 1 / 1 \times 1 = 1$.

Q Factor

[acoustics, biomedical, computational, electronics, mechanics, nuclear] QUALITY FACTOR, dimensionless parameter used as an indicator for the mechanical or electronic dampening of the MAGNITUDE pertaining to an oscillatory phenomenon. The Q factor is an indication of the inflicted AMPLITUDE reduction with respect to the free OSCILLATION. In ULTRASOUND scanning, for instance, low Q is required pertaining to DOPPLER imaging, and does not imply any value judgment of the material used to generate the specific acoustic frequency band. An ultrasound probe (for instance, made from PZT material) will have a dampening efficiency that is expressed as $Q = \nu_0 / \Delta\nu$, where ν_0 is the center frequency of the material or RESONANCE FREQUENCY and $\Delta\nu$ the bandwidth of the mechanism with enclosure and materials in close contact with the walls of the piezoelectric structure, acting as dampeners. A high Q factor is an

indication of a narrow resonance peak. In nuclear reactions the Q VALUE has a different meaning from the Q factor, in that case indicating the net gain in kinetic ENERGY. Alternatively, in MECHANICS it relates to the length of the crank arm for a bicycle paddle. The bicycle paddle DISTANCE between the attachment to the axis through the gear sprocket (chain ring) for the chain and the platform bicycle pedal (*also see* QUALITY FACTOR) (see Figure Q.2).

Figure Q.2 (a,b) Damping effect for amplitude of oscillation (either mechanical or electronic) for conditions defining specific Q factors.

Q of reaction

[atomic, nuclear] See Q VALUE.

Q Phase

[thermodynamics] Heterogeneous state, composite system of phases that are in MUTUAL STABLE EQUILIBRIUM. For alloys, the Q -phase designates a condition of specific structure. In the aluminum–copper–magnesium–silicon alloy for instance, the Q phase is the compound $\text{Al}_5\text{Cu}_2\text{Mg}_8\text{Si}_6$. This alloy Q phase is formed during the SOLIDIFICATION process and has inferior mechanical properties. The alloy Q phase can be predicted and subsequently avoided by a computational thermodynamic approach, using isothermal phase diagrams with regard to the PHASE stability (see Figure Q.3).

Figure Q.3 (a,b) Electronic matrix with respect to the Q phase of Cooper pair electrons in an alloy structure describing the superconductivity conditions under the influence of an applied external magnetic field, where the magnetic field direction controls the complex quantum state with respect to the Q phase. The Q -phase diagram illustrates the Q vectors associated with the spin-density waves for the alloy CeCoIn_5 (cerium-cobalt-indium), describing the magnetic Bragg positions corresponding to the magnetic field direction in reciprocal space. In this situation, the Q phase illustrates the quantum critical point defining magnetically induced superconductivity.

Q Space

[computational, condensed matter] Q space analysis in computational data analysis provides an alternative to diffusion-weighted imaging (DWI). Q space provides an estimation of maximum likelihood of processes and events, for instance the SCATTERING OF RADIATION by particles or discontinuities. Q space analysis involves plotting the scattered wavefunction (and respective PHASE function) magnitude versus the MAGNITUDE of the scattering WAVE vector: $q = (4\pi/\lambda) \sin(\theta/2)$, using a double log plot. The Q space analysis allows for the estimation of the probability density function (PDF) for molecular DIFFUSION without the need for assumptions with regard to a specific Gaussian shape. One particular application is in the IMAGE analysis for magnetic resonance imaging (MRI). Q space represents wavelength (λ) (long wavelength corresponding to small q) with respect to displacement (location: r). It is a transform from the diffusion TENSOR (see Figure Q.4).

Figure Q.4 Q -space map obtained by magnetic resonance imaging. Quantitative analysis of Q -space (QUAQ) data for a section of a human pons acquired on a 14.1T VARIAN NMR imager with 90 Q vectors (corresponding diffusion gradients with 3 strengths $\times$ 30 directions): estimated distribution of neuronal bundles illustrated by cylinders superimposed over a high-resolution spin-echo image of a transverse section of a human rostral pons. The predominant orientation of the neuronal bundles is indicated in blue for the z -direction, green for the x -direction, and red for the y -direction (out of plane axis). (Courtesy of L. Guy Raguin.)

Q Switching

[optics, quantum] Pulsing mechanism used to form an extremely high radiance laser pulse with an extremely short duration, that is, *Q*-switched laser. *Q*-switched laser pulses are convenient in tattoo removal based on the short thermal interaction, preventing thermal DIFFUSION, which would result in ambient damage. *Q*-switched laser pulses are in the order of nanosecond duration. The pulsation is achieved by influencing the losses in the cavity, diminishing the laser emission process while gaining on INVERSION. The reduction in “emission” of the LASER acronym can be achieved by any of the following means: rotating MIRROR, SATURATION of a programmable absorbing medium, acousto-optic modulation of the path within the cavity, and electro-optic modulation of the path within the laser cavity, for instance, by means of a Pockels CELL. The *Q* switching modulates the rate equation of the LASER action mechanism on an atomic level within Einstein’s population inversion process, with a time constant embedded in the DECAY constant of the cavity, indicative of the depletion of the EXCITED STATES. The loss is virtually instantaneously switched to “low” to release all the stored inverted state ENERGY as a short PHOTON pulse for the duration of the low loss. The pulse duration (τ_i) is a function of the IONIZATION decay rate as $dn(t)/dt = K\{N_i - N_{th}\}n(t) \approx (r_i - 1)/\tau_i$, where $r_i = N_i/N_{th}$ is the initial inversion ratio, with N_i the POPULATION INVERSION directly after switching and N_{th} the threshold inversion immediately after switching, and $n(t)$ is the cavity photon number (~number of excited states). *Q*-switched lasers generally operate in a pulse sequence range of hundreds of hertz to megahertz with below nanosecond pulse duration (e.g., picosecond laser pulse duration used for tattoo removal with minimal peripheral thermal damage, due to the short thermal diffusion time) at output energy levels exceeding J. In 1958, GORDON GOULD (1920–2005) proposed the concept of *Q* switching, but the practical implementation was applied in the state-of-the-art ruby laser of the day by Robert W. Hellwarth (1930–) and Fred J. McClung (1907–2014) in 1961 by means of a Kerr cell shutter, operating based on electrical switching placed within the laser cavity (see Figure Q.5).

Figure Q.5 Beautician applying a *Q*-switch laser for cosmetic skin modification based on photocoagulation processes.

Q Value

[chemical, nuclear, solid-state] In nuclear reactions, the Q value is an indication of the net gain in kinetic ENERGY (KE), standing with respect to the rest energy: $Q = \sum (Mc^2)_{\text{before}} - \sum (Mc^2)_{\text{after}} = \sum \sum KE_{\text{after}} - \sum \sum KE_{\text{before}}$, where $c = 2.99792458 \times 10^8$ m/s is the speed of LIGHT and M the respective masses in the processes. In PARTICLE physics, the Q value represents the DECAY of a particle; for instance, the decay for a NEUTRON is described in relativistic energy as $Q = (m_n - m_p - m_{\bar{\nu}} - m_e)c^2$, with m_n the neutron mass, m_p the proton mass, $m_{\bar{\nu}}$ the mass for the antineutrino, m_e the electron mass, and $c = 299792458$ m/s the speed of light. Not to be confused with the Q FACTOR (see [Figure Q.6](#)).

Figure Q.6 Diagram illustrating the mass equivalence with respect to the Q value for a nuclear fission process.

Q-T Interval

[biomedical] Time interval for each heart beat, defining the ventricular DEPOLARIZATION (Q ; in the QRS segment of the EKG) with respect to the subsequent atrial depolarization (T) for the next contraction of the atrium, lowed by the ventricular contraction, perfusing the body with BLOOD (see [Figure Q.7](#)).

Figure Q.7 (a,b) The relevance of the Q - T interval in the electrocardiogram, indicating the time it takes for the heart to contract and subsequently refill with blood before initiating the next contraction. The Q - T interval is a function of exercise history, the age, and gender of the individual, as well as the regularity and frequency of the standard heart rate. A long Q - T interval represents the deviations in the heart's electrical recharging system from the mean with respect to the overall population, and can be genetically defined or have correlation with a broad range of diseases, not necessarily heart related.

Quadrupole moment

[atomic] Description of the deviation from a spherical charge distribution in the NUCLEUS with respect to the nuclear moment, defined as $Q_e = (1/e) \int r^2 (3 \cos^2 \theta - 1) \rho d\tau$, where θ is the azimuth ANGLE in reference to the projection of the total SPIN of the charge ELEMENT $\rho d\tau$ in the direction where this is maximized for QUANTUM NUMBER $m = I$ (I is the TOTAL ANGULAR MOMENTUM for the spin) at location r , and $e = 1.60217657 \times 10^{-19}$ C is the ELECTRIC CHARGE. The quadrupole moment provides the expectation value for the charge distribution and respective spin angular momentum configuration. Note that the quadrupole moment is nonzero for nuclei that have the total angular momentum greater than or equal to one ($I \geq 1$). The quadrupole momentum can provide details about the internuclear forces. The quadrupole moment is negative for nuclei with a closed (spherical) shell and that possess an additional positive PARTICLE. A nearly closed shell will yield a quadrupole moment that has a positive denomination (prolate nuclear shape). The electric quadrupole moment for a nucleus can also be described in TENSOR format as a function of the wavefunction for the respective nuclear states (Ψ_N), for the corresponding Cartesian components x_i : $Q_e = \sum_{k=1}^Z e (3x_i x_j - \delta_{ij} r^2) |\Psi_N|^2 d\tau$, where δ_{ij} is the KRONECKER DELTA FUNCTION (see Figure Q.8).

Figure Q.8 (a) Macroscopic quadrupole rods of an analyzer from a triple quadrupole mass spectrometer, and (b) diagram of the associated field distribution under the wavefunction affected changes in nuclear states with a perturbation in magnetic field distribution and associated quadrupole moment. The magnetic moment is a direct function of the magnetic strength of each of the poles and the respective separation between the various poles, constructing a complex vector summation subject to recursive influences from the “other” poles performed in a perturbation analysis.

Quality factor

[nuclear, optics] The quality factor is used in several locations in PHYSICS; ionizing radiation and laser radiation are two specific scientific designations of interest. With respect to ionizing radiation the quality factor is an equivalence indicator for RADIATION in comparison to human risk during exposure of X-RAY radiation. The following quality factor applies to the respective sources of radiation: γ , $Q = 1$; β , $Q = 1$; α , $Q = 20$; NEUTRON, $Q = 10$, proton (high energy), $Q = 10$. In laser design the quality factor dictates the efficiency of a laser cavity: $Q_f = \omega t_{\text{out}} / \delta_c = (4\pi L / \lambda) (1 / \delta_c)$, for a WAVE with wavelength λ of a cavity with time of flight at the output mirror $t_{\text{out}} = 2L / c$ ($c = 2.99792458 \times 10^8$ m/s is the speed of LIGHT and L is the laser cavity length), with δ_c the “loss coefficient” expressing the fractional loss over the

REFLECTION—transmission path. In this case the quality factor determines the line width, $\Delta\omega = 2\pi\Delta\nu$ ($\nu = c/\lambda$ the frequency), of the laser beam (see Figure Q.9).

Type of radiation	Rad	Q Factor	Rem
X-ray	1	1	1
Gamma ray	1	1	1
Beta particles	1	1	1
Thermal neutrons	1	5	5
Fast neutrons	1	10	10
Alpha particles	1	20	20

Figure Q.9 Quality factor with respect to dose equivalence for radiation exposure.

Quanta

[atomic, general, mechanics, optics, photons, quantum] Discrete quantities of ENERGY or charge, or mass. The QUANTUM of charge was named by George Johnstone Stoney (1826–1911) in 1891 as the electron. The quantum for electromagnetic RADIATION is the PHOTON, named in 1926 by Frithiof Wolfers (1890–1971) and Gilbert N. Lewis (1875–1946).

Quantification

[acoustics, computational, image] Mechanism used in ULTRASONIC IMAGING applied to boundary detection. The acoustic quantification provides a regional analysis.

Quantized Dirac equation

[computational, energy, general, thermodynamics] Mathematical description that applies to the interaction of the electric field resulting from the electron current density of a system, with associated ELECTRO-MAGNETIC FIELD configuration (atomic, or generalized QUANTUM—mechanical particles) as well as the photons entering and leaving the system on the electron “self-field” expression. The electron current density for a flow of charges with net charge q : $J^\mu(x) = iq/2 [\Psi(x), \gamma^\mu \Psi(x)]$ ([,] the commutator; γ^μ the set of four 4×4 Dirac matrices defined by $\{\gamma^\mu, \gamma^\nu\} = 2g^{\mu\nu}$, where $g^{\mu\nu} = \text{diag}(-1, +1, +1, +1)$ is the matrix diagonal and $\{\gamma^\mu, \gamma^\nu\}$ is the anticommutator). The adjoint wavefunction $\bar{\Psi}(x)$ is defined through the Hermitian conjugate: $\gamma^{\mu*} = -\mathbb{A}\gamma^\mu\mathbb{A}^{-1}$, as $\bar{\Psi}(x) = \mathbb{A}\Psi^*(x)$, where $\mathbb{A}$ is the 4×4 Hermitian matrix. This provides the function of the WAVEFUNCTION ($\Psi(x)$) SOLUTION to the SCHRÖDINGER EQUATION as $[\gamma^\mu \partial_\mu + iq\gamma^\mu (\mathcal{A}_\mu(x) + \mathcal{A}_\mu^{\text{ext}}(x)) + m_0] \Psi(x) = 0$, with

$$\partial_\mu = \left(\frac{\partial}{\partial x_0}, \nabla \right)$$

(∇ the Laplace second derivative matrix) the differential operator, $\mathcal{A}_\mu^{\text{ext}}(x)$ the (classical) external electromagnetic field, $\mathcal{A}_\mu(x)$ the field from the entering photons combined with the “virtual photons” of the electron self-field, and m_0 the charge mass associated with q .

Quantum

[nuclear, quantum] A discrete quantity of radiative (electromagnetic) ENERGY equal to the product of its frequency and Planck's constant. The equation is $E = h\nu$ (see [Figure Q.10](#)).

Figure Q.10 Postage stamp dedicated to the quantum concept, specifically pertaining to light, dedicated to Max Planck (1858–1947).

Quantum chromodynamics

[general, high-energy] COLOR identification of GLUON exchange with respect to the interaction between quarks. The color QUANTUM gluon has a spin 1 and is a massless VECTOR BOSON. The vector boson is described by means of a four-dimensional wavefunction. The GLUON offers eight different coupling mechanisms that are represented by color-GAUGE THEORY as eight massless gluons. The color denominations are approximately as follows: green versus antigreen: magenta; RED versus antired: cyan; blue versus antiblue: yellow; and so on, less well defined in some cases.

Quantum concentration

[energy, thermodynamics] The number of particulate constituents per unit volume with a separation DISTANCE that is equal to the DE BROGLIE WAVELENGTH, defined as $n_Q = \left(\frac{mk_b T}{2\pi\hbar^2} \right)^{3/2}$, with $\hbar$ the Planck constant h divided by 2π , $k_b = 1.3806488 \times 10^{-23} \text{ m}^2 \text{ kg/s}^2 \text{ K}$ the Boltzmann coefficient, and m the mass of the elementary unit forming the system or GAS.

Quantum dot (QD)

[biomedical, quantum, solid-state] Macromolecular crystalline structure that has QUANTUM mechanical properties. The quantum dot concept is frequently associated with nanoparticles. In many cases, the quantum dot has a semiconductor material base. The quantum dot can have photoluminescent properties. QDs are also used for biological and chemical marking and tracking due to the highly configurable nature. The name originates from the discovery by ALEXEI EKIMOV (1945–) in a GLASS matrix, published in 1975, and independently in colloidal solutions by Louis E. Brus (1943–) in 1980. The term “quantum dot” was coined by Mark Reed (1955–) in. Quantum dots have an ability to convert LIGHT into ELECTRICITY and vice versa. They have found applications in a range of scientific device designs, ranging from quantum computers, solar panels, light emitting devices, cellular imaging, to siRNA delivery, next to target tumor detection and therapeutic targeting (see [Figure Q.11](#)).

Figure Q.11 Graphical representation of the quantum dot principle. (Courtesy of RusNano, Moscow, Russia.)

Quantum electrodynamics (QED)

[atomic, computational, energy, general, thermodynamics] Relativistic QUANTUM THEORY-based physics principles introduced by Dirac. Electromagnetic phenomena where the electric field is mathematically considered to be ruled by the laws of QUANTUM MECHANICS. One specific quantum phenomenon is the PHOTON. In theoretical physics the merger of the MAXWELL EQUATIONS with SPECIAL RELATIVITY formed the relativistic quantum theory known as QUANTUM ELECTRODYNAMICS (QED). The mathematical treatment of charged particles will range from classic, nonrelativistic to relativistic. QED has its roots in the revelation of the quantum hypothesis for LIGHT (i.e., photons with ENERGY $E = h\nu$) by Max Planck in 1900. Additional fundamental atomic interactions such as ANNIHILATION and PAIR PRODUCTION require a quantized energy format as well as relativistic theory. The first use of QED was by WERNER KARL HEISENBERG (1901–1976) and WOLFGANG ERNST PAULI (1900–1958) when they introduced a spinless relativistic PARTICLE in 1929. Around the same time a relativistic particle with spin $\hbar/2$ was introduced that relies on PAUL ADRIEN MAURICE DIRAC'S (1902–1984) relativistic WAVE EQUATION, where $\hbar = h/2\pi$ is derived from MAX KARL ERNST LUDWIG PLANCK'S (1858–1947) constant h . The ELECTRON SPIN is described perfectly well in the Dirac interpretation of the special relativistic approach to quantum mechanics known as quantum electrodynamics. One notable example of QED is the QUANTIZED DIRAC EQUATION. QED applies to electrons, electromagnetic RADIATION, and ELEMENTARY PARTICLES such as muons, except for hadrons that are governed by strong interaction, which makes the QED theoretical approach more a phenomenological exercise. QED also allowed for the introduction of ANTIMATTER, which helped balance the energy scales in nuclear physics. It forms the basis for the theoretical description in high energy physics.

Quantum field theory

[computational, energy, general, thermodynamics] Interaction of MATTER with each other based on the hypothesis that each object or phenomenon is based on PARTICLE interaction, where each particle has a GRAVITATIONAL FIELD surrounding it that decays with DISTANCE. Generally, all forces between objects are maintained by particle stream, where GRAVITATION is enforced by the hypothetical massless GRAVITON particle. The quantum field theory attempts to portray forces and fields as a physical presence. This concept followed the description of the PHOTON as the “particle” carrying the ENERGY of the electric and MAGNETIC FIELD fluctuations. When enough energy $E = mc^2$ is present in any form, theoretically a real particle can be created to replace the virtual one. Quantum field theory has four assumptions: (1) quantum fields are the essence (there are no other parameters); (2) all quantum fields obey the laws of QUANTUM MECHANICS as well as special relativity; (3) field MAGNITUDE in any location is the likelihood of interacting with a particle at a specific location; and (4) the field QUANTA provide an interaction that is equivalent to the general concept of classical field theory. In quantum field theory, the concept of DEGREES OF FREEDOM is replaced by operators, where one example is the HAMILTONIAN. Another switch is the exchange of POISON BRACKETS in general quantum mechanics by commutators. The way quantum field theory is formulated offers a mechanism to describe and explain the FOUR FORCES of nature: GRAVITY, weak, electromagnetic, and strong.

Quantum fluids

[computational, energy, fluid dynamics, general, thermodynamics] Fluids that have the apparent property of remaining LIQUID at ABSOLUTE ZERO temperature and zero pressure. By definition, a quantum fluid has a ZERO-POINT ENERGY that is comparable with the potential energy associated with the interparticle forces. This property is the definition of fluid, while the THERMAL ENERGY brings it into the quantum field. These fluids have a remarkably large zero-point energy while possessing extremely small interatomic forces. Both factors contribute to the prevention of forming a solid. Examples of quantum fluids are electron “GAS” in sodium, nuclear MATTER in general, NEUTRON matter, and helium: ^3He and ^4He .

Quantum gas

[energy, thermodynamics] Gas or LIQUID solution that has a concentration (n_{gas}) that is greater than or equal to the QUANTUM CONCENTRATION: $n_{\text{gas}} \geq n_Q = \left(mT/2\pi\hbar^2 \right)^{3/2}$. The quantum gas can be either fermions

or bosons, but in contrast with the GAS in the classical regime the FERMI GAS behaves significantly different from the Bose gas.

Quantum jump

[general] The transition of an electron in a high ENERGY (initial energy state: E_i) orbit to a low energy orbit (final energy state: E_f), or ultimately GROUND STATE. The electron orbits are defined in the BOHR ATOMIC MODEL, described by NIELS HENRIK DAVID BOHR (1885–1962). The change in ENERGY LEVEL in the atomic model is associated with a change in the kinetic energy of the ELECTRIC CHARGE; hence, the electron will accelerate. The accelerated charge with an associated electric field will generate a changing MAGNETIC FIELD and hence produce electromagnetic RADIATION, that is, LIGHT, with frequency ν expressed by $h\nu = E_i - E_f$, where $h = 4.1356692 \times 10^{-15}$ Js is the Planck constant.

Quantum level

[general] ENERGY level of an electron or of any atomic system, distinct from any other of its energy levels by discrete quantities dependent on Planck's constant.

Quantum liquid

[astrophysics/astronomy, computational, energy, fluid dynamics, mechanics, quantum, thermodynamics] Concept introduced by LEV LANDAU (1908–1968), specifically for “Bose” type liquids (*also see* BOSE LIQUID).

Quantum magnet

[astro, biomedical, electric, quantum, solid-state] Magnet based on the MEISSNER EFFECT. MAGNETIC FIELD resulting from the transition of a superconductor to the superconducting state.

Quantum mechanics

[computational, electric, energy, general, nuclear, thermodynamics] Theoretical approach to phenomena that are fundamentally discrete in operation; changes occur in increments. Examples of quantized phenomena are angular atomic and subatomic momentum, charge transfer, electromagnetic interactions (e.g., photons), PARTICLE interaction (e.g., COLLISION), virtual particles (QUANTUM ELECTRODYNAMICS), and SPIN (specifically ELECTRON SPIN). One specific phenomenon that falls under quantum mechanics is the description of object MOTION by DE BROGLIE WAVES, specifically for electrons orbiting around a NUCLEUS. One specific application of the de Broglie wave theorem is in ELECTRON MICROSCOPY. The early twentieth century work of Heisenberg on the matrix theory, and the theoretical approach introduced by PAUL ADRIEN MAURICE DIRAC (1902–1984) on the transformation theory and the WAVE MECHANICS from ERWIN RUDOLF JOSEF ALEXANDER SCHRÖDINGER (1887–1961) all converged to the principle of QUANTUM MECHANICS. Under certain conditions, quantum mechanics is also referred to as wave mechanics, specifically in reference to the electron orbit described by de Broglie waves. The de Broglie wave can be considered as prescribing a standing wave for the electron in an orbit, which can be shown to follow the format of the electron packing sequence in orbital layers as described by NIELS HENRIK DAVID BOHR (1885–1962) due to the discrete nature of the boundary conditions for a standing wave. The science of description of atomic

systems in terms of discrete quantum states (*also see* SCHRÖDINGER WAVE EQUATION, WAVE MECHANICS, QUANTUM THEORY, QUANTUM PHYSICS, *and* QUANTUM NUMBER) (see Figure Q.12).

Figure Q.12 Quantum mechanical aspect of electron orbits, in particular the application of the Schrödinger wave function probability distribution for the alleged position of the electron or respectively the physical de Broglie wave aspect to satisfy the boundary conditions for electron orbits presented by PRINCE LOUIS DE BROGLIE (1892–1987) in 1924 as part of his PhD dissertation. (Courtesy of Kenneth Snelson, <http://kennethsnelson.net/>.) Artist representation of the quantum model for electron orbital filling based on the energy levels with reference to the de Broglie wave model from Louis de Broglie. Louis de Broglie proposed that—in equivalence to how ALBERT EINSTEIN (1879–1955) had shown light to have a dual nature—acting both as light waves and particle photons, moving matter may also be represented by a dual character. De Broglie hypothesized that the electron can act as a wave as well as a particle. As an example de Broglie used the electron in Bohr's hydrogen atom. De Broglie provided evidence that his "matter waves" fits perfectly in velocity and wavelength around Bohr's hydrogen atom model's quantized concentric orbits. In the first shell, closest to the nucleus, a single wave could fit resembling a snake biting its own tail. In shell two, there would be two waves; three waves would fit in shell three, and so on. Two years after the publication of the de Broglie dissertation, in 1926, Erwin Schrödinger (1887–1961) adapted the de Broglie's matter wave idea to create the Schrödinger wave equation, which soon became one of the principle tools of quantum physics. In the following year, that is 1927, the Davisson–Germer experiment (CLINTON JOSEPH DAVISSON [1881–1958] and LESTER HALBERT GERMER [1896–1971]) proved that there are indeed electron matter waves, providing evidence for de Broglie waves. The concepts expressed by Louis de Broglie are in this illustration interpreted on an artistic level. In de Broglie model an object comprising the following requirements and, respectively, properties: (1) As with Bohr's quantized electron, a de Broglie orbital wave remains at a single energy shell and can move from one shell to another only by absorbing or transmitting energy, in the form of light (i.e., accelerated charge motion). (2) The electron's negative electric charge is distributed evenly over the orbital circle's circumference. (3) The de Broglie orbit is defined both by orbital magnetism and top-like angular momentum. (4) The orbit incorporates the electron particle's intrinsic spin (as presented by George Uhlenbeck [1900–1988] and Samuel Abraham Goudsmit [1902–1978] in 1925) with the North and South Poles either adding to the orbit's magnetism or, by inverting, subtract from it. (5) De Broglie matter waves are matter-like. In similarity to macro pieces of matter, de Broglie waves occupy exclusive space. Several respective orbits cannot be in the same space at the same time. When the speed of an electron increases, the de Broglie wavelength shrinks by a quantized unit and vice versa. This process may be thought of as resembling striking different notes on a piano, but unlike a glissando for playing a slide-trombone. At each higher shell or orbit the electron slows down and increases its de Broglie wavelength by one notch. This quantization describes the main feature of the atom model described by NIELS BOHR (1885–1962) in 1913 and the associated orbital jumps matching the energy changes indicated in the hydrogen's spectrograph. On initial interpretation the wave for the first orbit is only half the size, unable to surround the equator, the one-wave orbit inherently takes up space on a small meridian of the sphere and hence becomes a 2p electron. Because the electron completes its circle in half the time of the 2s state and because, as illustrated by its transparent cone, the orbit extends outward with respect to the nucleus. At the third shell, de Broglie's original three-wave equatorial orbit complex is represented by the 3s state. When reduced to a two-wave orbit, this will become the 3p state. The final one-wave orbit is identified by the 3d state. The velocity and wavelength for the respective 3s, 3p, and 3d are the same. The smaller the orbit fitting the electron shell, the farther it will project distal to the nucleus. The far-right illustration represents the full range of orbits available to hydrogen atom's electron, from the first shell through the fifth. The s, p, d, f ... electron orbit labels are derived from of the old quantum theory and the ellipsoidal orbit model described by Arnold Sommerfeld (1968–1951) in 1916, which were intended to satisfy the azimuthal quantum number symbolized by (lowercase L). The quantum number describes the electron's angular momentum for orbits at each shell. Sommerfeld's ellipsoidal shapes ranged from true

(Continued)

Figure Q.12 (Continued) circles, to ovals, progressing to straight lines. The de Broglie's matter waves represented a distinctly different interpretation from Bohr's orbiting electron. Alternatively, despite Sommerfeld's ellipsoids extending out from the nucleus, both physicists' atoms were only two-dimensional, that is, flat as a pancake. Irving Langmuir (1841–1957) defined a list of eleven postulates describing the Lewis–Langmuir atom model (see [LANGMUIR](#)). Postulate 1: there is symmetry in the atomic configuration. Postulate 2: the electrons in any given atom are distributed through a series of concentric (nearly) spherical shells, all of equal thickness. Hence, the mean radii of the shells formulate an arithmetic series 1, 2, 3, 4, and the respective effective orbital areas are in the ratios 1: 22; 32; 42. Postulate 3: each shell is divided into cellular spaces, respectively cells, each occupying equal areas in their respective shells and are distributed over the surface of the shells according to the symmetry suggested in Postulate 1. As a result, the first shell contains 2 cells, the second 8, third 18, and the fourth cell holds 32.

Quantum number

[atomic, computational, nuclear, quantum] One of a set of integral or half-integral numbers, one for each degree of freedom, which determines the state of an atomic system in terms of the constants of nature. A QUANTUM MECHANICS approach to determining the ENERGY of electrons in an ELEMENT or ION is based on the results obtained by solving the SCHRÖDINGER WAVE EQUATION for the HYDROGEN ATOM. The various solutions for the different energy states are characterized by the three main quantum numbers: n , ℓ , and m_ℓ . Each orbital has an associated characteristic shape, which reflects the MOTION of the electron pertaining to that particular orbital. This motion is hence characterized by an angular momentum defined by the angular velocity of the electron revolving around the NUCLEUS in its orbit. Electrons in an atom reside in shells characterized by a particular value of n , the PRINCIPAL QUANTUM NUMBER. Within each shell an electron can occupy an orbital that is further characterized by an ORBITAL QUANTUM NUMBER, ℓ , which can take all values in the range $\ell = 0, 1, 2, \dots, (n-1)$; these conditions are traditionally termed “s,” “p,” “d,” “f,” and so on orbitals. Other quantum states are in the description of orbital momentum and orbital spin, where L represents the ORBITAL ANGULAR MOMENTUM of the electron, S represents the SPIN (which cannot change, since that would mean a reversal of rotation direction), J represents the TOTAL ANGULAR MOMENTUM, with M_L the MAGNETIC moment and M_S the spin moment, and in reference $n = 1, 2, 3, 4, \dots$ is the primary quantum number, $\ell = 0, 1, 2, \dots, (n-1)$ the orbital quantum number, and $m_\ell = \ell, \ell-1, \dots, 0, \dots, -\ell+1, -\ell$ the MAGNETIC QUANTUM NUMBER. Similar to an electron moving in its orbital revolution around a nucleus, the electron spinning about its axis has associated with its rotation a well-defined angular momentum. The quantum number m_ℓ is a subset of the quantum number ℓ , where there are $(2\ell+1)$ values associated with each m_ℓ for each value of ℓ , representing the configuration for the s-orbital ($\ell = 0$), three p-orbitals ($\ell = 1$), five d-orbitals ($\ell = 2$), and so on. Furthermore, $m_s = -(1/2), +(1/2)$ represents the spin quantum number for the electrons that identifies the orientation of the spin of one electron relative to those of other electrons in the system. The spin quantum number is associated with the fact that a single electron in free space has a fundamental property, called spin. The spin of the electron represents an inhomogeneous asymmetrical charge distribution spinning around its own axis. Each electron in its orbital configuration (e.g., Bohr model, Rutherford model) is characterized by four base quantum numbers (see [Figure Q.13](#)).

Figure Q.13 Graphical representation of the atomic orbital configuration based on quantum number preferences.

QUANTUM NUMBERS		
SYMBOL	DESCRIPTION	RANGE OF VALUES
n	Principal quantum number: describes the “proximity” to the nucleus, i.e., the range of orbital motion and associated energy levels	1, 2, 3, etc.
ℓ	Azimuthal/orbital quantum number: largely determines the shape of subshell 0 for the s orbital, 1 for the p orbital, etc.	$(0 \leq \ell \leq n-1)$; for instance under the condition $n = 3$; $\ell = 0, 1, 2$ with associated “levels” (s, p, d)
m_ℓ	Magnetic quantum number: defines the orientation of a subshell’s shape. Examples are p_x , p_y , and p_z	$-\ell \leq m_\ell \leq \ell$, for instance under the condition $\ell = 2$, $m_\ell = -2, -1, 0, 1, 2$
m_s	Spin quantum number	Only two possible values for a single electron: $+1/2$ or $-1/2$

Quantum of action (h)

[general] The oscillatory “wavefunctions” in NIELS HENRIK DAVID BOHR’s (1885–1962) atomic model (influenced by LOUIS DE BROGLIE [1892–1987]) could only be satisfied if the WAVE would fit a “circumference,” and hence the closed wave turned out to have discrete values that had a constant with the units of ENERGY multiplied by time ($J \cdot s$), which was the equivalent of momentum multiplied by the traversed DISTANCE, a parameter known as “action” in classical MECHANICS. The constant was derived by MAX PLANCK (1858–1947) as PLANCK’S CONSTANT: $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$, which he referred to as the “quantum of action,” due to the discrete nature of the phenomenon. The orbital momentum in classical terms had the following condition for an electron orbit with mass m_e at radii r_n , traveling with discrete velocity v_n : $m_e r_n v_n = n(h/2\pi)$, with n the ordinal for the discrete ORBITS.

Quantum optics

[computational, energy, optics] QUANTUM THEORY pertaining to the bandwidth of optical wavelengths (i.e., visible LIGHT). The processes of detection of light, and propagation as well as generation are all subject to the QUANTUM effects; one specific example is in the coherence of laser light. The topic of “squeezed states” has special significance for the quantum optical approach.

Quantum orbital angular momentum

[atomic] The orbital angular momentum is subject to classical theory based on the fact that there are no external forces; hence, no torque acting and conservation rules apply. The ORBITAL ANGULAR MOMENTUM (L) is quantified as spherical harmonic functions as a SOLUTION to the SCHRÖDINGER WAVE EQUATION with discrete values for the MAGNITUDE expressed as a function of the angular quantum number (ℓ): $L = \hbar \sqrt{\ell(\ell+1)}$, where $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ the Planck constant. Similarly, the z -component of the angular momentum has eigenvalues: $L_z = m_\ell \hbar$, with m_ℓ the discrete MAGNETIC QUANTUM NUMBER (also see QUANTUM NUMBER).

Quantum physics, electron shells

[atomic, general, mechanics, nuclear, quantum] The field of PHYSICS that specializes in the theoretical description of events and phenomena that are discrete in nature, specifically pertaining to atomic and nuclear procedures and processes. Quantum physics made its introduction in the 1920s. Quantum physics encompasses, but not limited to, de Broglie waves (introduced by LOUIS DE BROGLIE [1892–1987]), QUANTUM ELECTRODYNAMICS (as introduced by PAUL DIRAC [1902–1984]), the PAULI EXCLUSION PRINCIPLE (as introduced by WOLFGANG PAULI [1900–1958]), relativistic QUANTUM THEORY, the HEISENBERG UNCERTAINTY PRINCIPLE (introduced by KARL HEISENBERG [1901–1976] in 1927), Schrödinger’s work (ERWIN SCHRÖDINGER [1887–1961]),

and the description of **ANTIMATTER** (first experimental indication, the “antielectron,” the positron, by **CARL ANDERSON** [1905–1991] in 1932 (with postulation records dating back to 1928), followed by the antiproton in 1955 and the **ANTINEUTRON** in 1956). The **ZEEMAN EFFECT** is another aspect of quantum physics as well (*also see* **QUANTUM NUMBER**, **QUANTUM MECHANICS**, and **QUANTUM THEORY**).

Quantum randomness

[general] The fact that under probability theory **IDENTICAL PARTICLES**, or **ENERGY** packages (e.g., photons), subjected to identical circumstances (i.e., identical boundary conditions) do not necessarily act in an identical manner.

Quantum spin angular momentum

[atomic] **ELECTRON SPIN** angular momentum belonging to the Dirac relativistic **WAVE** mechanical phenomenon (**PAUL DIRAC** [1902–1984]) as a component of the atomic angular momentum, defined by the **SPIN** quantum number s , as $L_s = \sqrt{s(s+1)}\hbar$, where $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ the Planck constant. The z -component of the electron spin is linked with the **MAGNETIC** moment by Dirac as having an intrinsic spin with a $g_s = 2$, value that is twice as large as for the corresponding **ORBITAL ANGULAR MOMENTUM**: $L_{s,\chi} = m_s \hbar$, with $m_s = \pm(1/2)$ the magnetic spin quantum number. The g -factor introduces a correction for the relationship between the magnetic momentum and the angular momentum, based on the difference in charge density with respect to mass density (note that for the orbital **MOTION** the charge density matches the mass density and yields alternatively $g_s = 1$ with respect to the orbital angular momentum). The spin vector will precess with a Larmor frequency, different from the orbital angular momentum vector **PRECESSION** frequency.

Quantum state

[atomic, general, nuclear] Term defining the way in which an atomic system exists at any specific time. This state is often described by means of a complex mathematical function. *see* **QUANTUM LEVEL** (see [Figure Q.14](#)).

Figure Q.14 Atomic quantum states for calcium: the diagram illustrates one particular orientation only for a specific quantum number configuration.

Quantum theory

[atomic, general, nuclear, relativistic] The concept that ENERGY is radiated intermittently in discrete units of definite MAGNITUDE called QUANTA, under conditions that may be subject to a relativistic approach. The basic principles of quantum theory date back to BLACK BODY radiation concepts from 1859 by the German scientist GUSTAV ROBERT KIRCHHOFF (1824–1887). This was followed by the hypothesis published in 1900 by MAX PLANCK (1858–1947) that energy can only be emitted or absorbed in discrete quantities. On the basis of the experiential observations in 1911 by ERNEST RUTHERFORD (1871–1937) leading to the nuclear model of the ATOM, NIELS HENRIK DAVID BOHR (1885–1962) developed the atom model in 1913, providing additional building blocks that illustrated that classical MECHANICS does not apply on an atomic level. The theoretical transition was fully made by the contributions of ERWIN SCHRÖDINGER (1887–1961) in 1925, partially based on the work of LOUIS DE BROGLIE (1892–1987) published in 1924. Additional components forming the complete story resulted from the HEISENBERG UNCERTAINTY PRINCIPLE introduced in 1927 by WERNER WEISENBERG (1901–1976). Over the years many refinements and additions followed, but the foundation evolved over a time span stretching out over more than 60 years. Also see QUANTUM MECHANICS (*also see* QUANTUM PHYSICS *and* QUANTUM NUMBER).

Quantum total angular momentum

[atomic, quantum] The superposition of the orbital angular quantum effect and the SPIN quantum effect. Under conditions there may be coupling of the spin and ORBITAL ANGULAR MOMENTUM, specifically under the influence of a weak external MAGNETIC FIELD (*also see* L–S COUPLING, QUANTUM NUMBER, TOTAL ANGULAR MOMENTUM, *and* ZEEMAN EFFECT).

Quantum tunneling

[computational, quantum] QUANTUM mechanical phenomenon where a PARTICLE migrates through an ENERGY BARRIER described as a tunnel that under classical PHYSICS would not be attainable. The *quantum tunneling* process was observed by ANTOINE HENRI BECQUEREL (1852–1908) in 1896 and later theoretically defined by GEORGIY ANTONOVICH (GEORGE) GAMOW (1904–1968) around 1928. The “transmission coefficient (T_Q)” for the PROBABILITY of a particle (mass m) with energy E_{particle} traveling through a POTENTIAL BARRIER with height $V_{\text{barrier}}(x)$, which is a function of DISTANCE (r) to the core of the MOLECULE/ATOM, is given as

$$T_Q = \exp\left(-2 \int_{r_1}^{r_2} \sqrt{\left\{(2m/\hbar^2)[V(r) - E]\right\}}\right) / \left\{1 + (1/4)\exp\left(-2 \int_{r_1}^{r_2} \sqrt{\left\{(2m/\hbar^2)[V(r) - E]\right\}}\right)\right\}^2,$$

where $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ Planck's constant. Also found described as *tunneling*. (see Figure Q.15).

Figure Q.15 Quantum tunneling with respect to the energy configuration of the nucleus of an atom, respectively an atomic model.

Quark

[atomic, general, high-energy] Elementary PARTICLE with the following energetic and momentum designations: first generation: “up” and “down;” second generation: “CHARM” or “strange;” and third generation: “top” and “bottom or beauty.” The subgroup of three varieties of quarks, up, down, and strange, have a fractional charge of $(1/3)e$ and $(2/3)e$, where e represents the standard electron charge. Quarks have standard half spin: $s = 1/2$. They are the latest in FUNDAMENTAL PARTICLES that are known and verified based on the state-of-the-art technology of MEASUREMENT as well as what can be mathematically validated. All “higher order” particles, such as neutron and proton, are constructed of quarks, referred to as hadrons. Electrons (LEPTON) are seemingly stand-alone particles, based on the knowledge at the time of this description. Nonetheless, there are indications that electrons themselves also exhibit quark equivalent “flavors.” Quarks are never found as isolated particles; they are always part of the collective of quarks in the HADRON. A PROTON is composed of two “up” quarks and a “down” quark; a NEUTRON is constructed from the GLUON “strong-force” COHESION between one “up” quark and two “down” quarks. Another particle is, for instance, the PION, constructed from an “up” with an “anti-down” quark, or a “down” quark, combined with an “antiup” quark. In turn, electrons, neutrons, and protons form atoms that constitute the building blocks for MATTER as we know it and work with on a daily basis. The quark concept was introduced in 1964 by both MURRAY GELL-MANN (1929–) and GEORGE ZWEIG (1937–), as independent hypotheses and experimentally verified starting in 1968 by experimental observations at the Stanford Linear Accelerator Center (now known as SLAC National Accelerator Laboratory). The “top” quark was verified as the last in a sequence as recent as 1995 (see Figure Q.16).

Figure Q.16 The concept of quark illustrated in nonrelativistic terms.

Quark and Antiquark Characteristics									
Flavor	Symbol	Charge	Spin	Baryon Number	Charm	Strangeness	Bottomness	Mass Range (MeV/c ²)	Generation
Quarks									
Up	u	$+\frac{2}{3}e$	$\frac{1}{2}h$	$\frac{1}{3}$	0	0	0	$1.7 \leftrightarrow 3.1$	1st
Down	d	$-\frac{1}{3}e$	$\frac{1}{2}h$	$\frac{1}{3}$	0	0	0	$4.1 \leftrightarrow 5.7$	1st
Bottom	b	$-\frac{1}{3}e$	$\frac{1}{2}h$	$\frac{1}{3}$	0	0	+1	172900 ± 600	3rd
Top	t	$+\frac{2}{3}e$	$\frac{1}{2}h$	$\frac{1}{3}$	0	0	0	$4190 + 180/-60$	3rd
Strange	s	$-\frac{1}{3}e$	$\frac{1}{2}h$		0	-1	0	$100 + 30/-20$	2nd
Charmed	c	$+\frac{2}{3}e$	$\frac{1}{2}h$	$\frac{1}{3}$	+1	0	0	$1290 + 50/-110$	2nd
Antiquarks									
Antiup	$\bar{u}$	$-\frac{2}{3}e$	$\frac{1}{2}h$	$-\frac{1}{3}$	0	0	0	$1.7 \leftrightarrow 3.1$	1st
Antidown	$\bar{d}$	$+\frac{1}{3}e$	$\frac{1}{2}h$	$-\frac{1}{3}$	0	0	0	$4.1 \leftrightarrow 5.7$	1st
Antibottom	$\bar{b}$	$+\frac{1}{3}e$	$\frac{1}{2}h$	$-\frac{1}{3}$	0	0	-1	172900 ± 600	3rd
Anitop	$\bar{t}$	$-\frac{2}{3}e$	$\frac{1}{2}h$	$-\frac{1}{3}$	0	0	0	$4190 + 180/-60$	3rd
Antistrange	$\bar{s}$	$+\frac{1}{3}e$	$\frac{1}{2}h$	$-\frac{1}{3}$	0	+1	0	$100 + 30/-20$	2nd
Anti-charmed	$\bar{c}$	$-\frac{2}{3}e$	$\frac{1}{2}h$	$-\frac{1}{3}$	-1	0	0	$1290 + 50/-110$	2nd

Quark, flavor of

[energy, general, quantum, relativistic] *See* **FLAVORS OF QUARKS** *and* **QUARK**.

Quartz

[biomedical, optics, solid-state] Optically transparent crystalline lattice structure. Quartz materials are optically active, resulting in a rotation of the **POLARIZATION** direction of transmitted **LIGHT**. Quartz has its special features derived from the polarized electronic state of the **LATTICE** structure. The **OPTICAL ACTIVITY** of quartz is attributed to the helical molecular structure of the quartz crystal. Quartz can be electrically excited to oscillate, acting as a **RADIO WAVE** emission source or tuning receptor for oscillating electric and electronic signals. Quartz can also be made to expand and contract under electrical excitation, forming an **ULTRASOUND** emission source. The chemical base for quartz is silicon and oxygen (SiO_2) (see [Figure Q.17](#)).

Figure Q.17 Raw white quartz; other color quartz crystals are also found. The color of the quartz is the result of “pollution” or doping by other elements, some of which are considered semiprecious gemstones (e.g., amethyst). Most common inclusions are metals as well as phosphorous compounds. Quartz is the second most abundant mineral found on the Earth’s surface. The pure quartz crystal is constructed from SiO_4 (silicon and oxygen).

Quasar

[astrophysics/astronomy] Acronym for “quasi-stellar radio source.” Star-like objects in the **UNIVERSE** that are outside the **MILKY WAY**. Quasars emit a broad range of electromagnetic **RADIATION**, with the most abundant amount of frequencies in the “radio” band of the spectrum. Quasars are presumably galactic cores (assemblies of many stellar sources), hypothetically incorporating “black holes.” The **RADIO** emissions are supposedly a secondary effect resulting from high-energy photons interacting with material outside the

quasar space, originally resulting from excessive high-temperature-based interaction for instance with the BLACK HOLE. The spectral lines of quasars form part of the verification process supporting the “BIG BANG THEORY,” based on the DOPPLER redshift, indicating the general EXPANSION of the universe (*also see* HUBBLE EFFECT) (see [Figure Q.18](#)).

Figure Q.18 Artist impression of the format describing the mechanism of operation for a quasar.

Quasicrystalline solid

[general, solid-state] Molecular or atomic configuration in a regular orderly three-dimensional pattern that is different from crystalline or amorphous (noncrystalline), while being nonrepetitive (not a regular LATTICE) forming a solid that is quasicrystalline.

Quasimonochromatic light

[general, optics] Whereas the term MONOCHROMATIC LIGHT indicates an extremely narrow linewidth of less than 0.5 nm, quasimonochromatic would be the accurate term for this, since the true meaning of monochromatic will described deep into the decimal aspect of the source definition, technically indicating an infinitely duration source. The shorter duration would indicate a lower number of harmonics, an extremely short pulse such as for a Q-switched laser renders a broad linewidth, approaching several nanometers.

Quasiparticle

[atomic, high-energy, optics] Many-body system that possesses excitation levels resembling those of free ELEMENTARY PARTICLES, but may have a convoluted interparticle interaction. One specific example is the Fermi liquid in the LANDAU THEORY, where the electrons of a medium at extremely low temperature (e.g., Helium) can essentially behave as free fermions, although bound (i.e., quasiparticle); this also forms one of the basics of SUPERCONDUCTIVITY and superfluidity. The main complication lies in the distribution function for the “PARTICLE” momentum with respect to the Fermi momentum, which for the ideal particle is a delta function; however, this may not hold true throughout all theoretical processes. In general, the FERMION forms the base for the quasiparticle; however, under special boundary conditions, bosons (term coined by PAUL DIRAC [1902–1984]; e.g., phonon, PLASMON, COOPER PAIR, SPIN WAVE, etc.) may also be considered quasiparticles.

Quasi-steady state

[astrophysics/astronomy, fluid dynamics, geophysics, mechanics, meteorology, thermodynamics] Intermediate states of a system that progress linearly in response to temperature, pressure, and volume changes. The EQUATION OF STATE for the system is well defined, specifically conforms to the IDEAL GAS LAW over discrete steps in time, and changes gradually between incremental episodes. Also known as the quasistatic process. When applied to the UNIVERSE, the Hubble constant would yield a fixed number under quasi-steady-state approximation; however, under longer period examination it will not, since then the process becomes transient. The quasi-steady-state approach is a linearization process with very specific boundary conditions, pertinent to the system under consideration. The considerations for when to label a process quasi-steady state rely on the characteristic time frame for the phenomena within the system; in particular, the processes with the shortest time frame are critical in the analysis. Additionally, the required accuracy of the analysis forms a major scaling factor in the assumption what may be considered quasi-steady state. In first order approximation, one may find that the accuracy is proportional to the relevant time scale (observation time divided by the time frame of the shortest event), and exhibits an exponential behavior. In first-order analysis, when observations are stationary within a time frame that is minimally five (5) times the shortest process of all the processes that define the system, then they can be considered quasi-steady state, with less than 0.7% error in the outcome. However, it will be incorrect to assume that all processes are independent from each other; hence, the exact error will be a convoluted calculation procedure, integrating all factors and interactions. Alternatively, when the consequences of a process are at least ten (10) times the duration of the initiating phenomenon (first-order), then those events can be considered quasi-steady state as well, and since this forms a recursive relation, the dependency may be more quadratic than exponential. These conditions may require one to be more strict due to the fact that they change the boundary conditions, as well as the process itself. One example is that heat DIFFUSION for a femtosecond (*Q*-switched) laser pulse is negligible within the time frame of interest, and hence the process and fallout

for ultrashort laser delivery is frequently quasi-steady state. NUMERICAL solutions to time-dependent equations are always performed under quasi-steady-state conditions, where the boundary conditions need to be adjusted at specified intervals, or dynamically, to account for changes resulting from external influences or due to the processes themselves (see [Figure Q.19](#)).

Figure Q.19 (a) Quasi-steady state for meteorological events: the big block of clouds remains steady while a remote steady flow of mountain air provides a backdrop of an active event. The event is still very stable and will not interfere with the contiguous cloud formation in the foreground that is apparently at a distance that remains unaffected by the boundary conditions from the flow pattern. The cloud concentration may move under the influence of atmospheric pressure and bring the clouds close enough to the mountain wave to disturb the equilibrium. (b) Drainage pipe flow that is considered steady state within a broad time frame; however, the flow rate and flow pattern are for instance influenced by the position of the Moon next to the water level in the back country, which in turn will be a function of precipitation and runoff from regional population concentrations and industrial complexes.

Taylor & Francis

Taylor & Francis Group

<http://taylorandfrancis.com>

Raab, Oscar (1876–1986)

[biomedical, optics] Medical student from Germany who described the principle of **PHOTOTOXICITY** as the light-mediated enhanced cytotoxicity of eosin on **SKIN** in 1898/1899 and named it photodynamic action. He reported that paramecia cells injected with the dye acridine orange resulted in **CELL** death when exposed to **LIGHT**. The discovery of phototoxicity led to medical applications in cancer treatment and was named photodynamic therapy (PDT). These pioneering efforts in **BIOMEDICAL OPTICS** used the phototoxic effect of the combination of certain dyes with light to treat skin cancer reportedly starting in the period from 1903 through 1907 and this was rapidly followed by the treatment of **EYE** tumors. An illustration of the importance of light in photodynamic therapy applications is specifically in a particularly hard to treat anatomical section: the brain. More easily and more frequently treated oncology conditions are in skin cancer and other superficial tumors, including but not limited to the urinary bladder and intestines (see [Figure R.1](#)).

Figure R.1 Diagram of Oscar Raab's (1876–1986) phototoxicity concept. Despite the significant influence on modern medicine, unfortunately no known images exist of Oscar Raab.

Rabi, Isidor Isaac (1898–1988)

[atomic, nuclear] Physicist from Austria (Prussian empire)/(Poland). Rabi is most known for his contributions to the understanding of the **MAGNETIC RESONANCE** and general magnetic properties of the atomic **NUCLEUS** and the evolution of magnetic resonance imaging (MRI), for which he received the Nobel Prize for Physics in 1944. Isidor Rabi's work on the magnetic moments of nuclei involved his prediction and verification that absorbed **ENERGY** from an externally applied electromagnetic **WAVE**, at the appropriate (**RESONANCE**) frequency, would flip the magnetic orientation of the recently discovered protons and neutrons. The **SPIN** would subsequently emit the identical amount of energy when reverting back to the

lower energy orientation. Rabi coined the term “MOLECULAR BEAM magnetic resonance” for this phenomenon. Rabi’s work also led to the development of the atomic clock (see [Figure R.2](#)).

Figure R.2 Isidor Isaac Rabi (1898–1988). (Courtesy of Columbia University Libraries; University Archives, Columbia University in the City of New York.)

Radial quantum number

[nuclear] As applied to a harmonic oscillator applied to Laguerre–Gauss modes. Although not used in general nuclear QUANTUM MECHANICS the radial quantum number (n_r) provides insight in the number of radial nodes of the (radial; in cylindrical coordinates) WAVE function and is tied to the PRINCIPAL QUANTUM NUMBER (n) as $n = n_r + \ell + 1$, where ℓ is the ORBITAL ANGULAR MOMENTUM quantum number, the azimuthal quantum number. In this context the radial quantum number defines the DISTANCE of the electron from the NUCLEUS in the Bohr model. Alternatively, the principal quantum number may also be found referred to as the radial quantum number (see PRINCIPAL QUANTUM NUMBER).

Radial wave equation

[nuclear] See SCHRÖDINGER EQUATION.

Radial wave function

[nuclear] See WAVE FUNCTION.

Radiance ($\Phi(\vec{r}, \vec{s})$)

[biomedical, electromagnetism, general, nuclear, optics] Radiant ENERGY; power emitted, transferred, or received as radiation (W). The radiance has an angular dependence that can be developed in a truncated series of polynomials. In most cases the function that is part of the differential equation can be developed in a series of power series solutions: Legendre polynomials, BESSEL FUNCTIONS, and Laguerre polynomials. Using Cauchy theorem, the expression can be developed in series of orthogonal polynomials: $f(x) = \sum_{k=0}^{\infty} A_k x^k$, as

$$\begin{aligned}\Phi(\vec{r}, \vec{s}) &= \sum_{n=0}^1 \sum_{m=-n}^n Y_n^m(\vec{s}) \Phi_n^m(\vec{r}) \\ &= Y_0^0(\vec{s}) \Phi_0^0(\vec{r}) + Y_1^{-1}(\vec{s}) \Phi_1^{-1}(\vec{r}) + Y_1^0(\vec{s}) \Phi_1^0(\vec{r}) + Y_1^1(\vec{s}) \Phi_1^1(\vec{r}) + Y_2^0(\vec{s}) \Phi_2^0(\vec{r}) + \dots\end{aligned}$$

Also found identified by the parameter $L(\vec{r}, \vec{s})$ (see [Figure R.3](#)).

Figure R.3 The difference in radiance from several floodlights with adjustable focal points.

Radiant energy fluence rate ($E^0(\vec{r}, t)$)

[astrophysics/astronomy, biomedical, energy, thermodynamics] Total radiant power incident on a surface from all directions per unit surface area. The fluence per unit time: $E^0(\vec{r}, t) = dH^0(\vec{r}, t)/dt = d\Psi(\vec{r}, t)/dt$. Also the integrated radiance ($L(r, \theta, \phi, t)$) over full SOLID ANGLE: $E^0(r, t) = \int_{4\pi} L(r, \theta, \phi, t) d\Omega$. Also known as fluence rate. In comparison, the ENERGY per unit area incident on a small sphere is the fluence ($\Psi(\vec{r}, t)$; also found as $H^0(\vec{r}, t)$). For a parallel, none scattered beam incident on a surface the radiant energy fluence rate reduces to “Irradiance,” for example, laser beam on clear semi-infinite medium (no reflective boundaries).

Radiant flux

[general] See RADIATIVE POWER.

Radiation

[atomic, general, optics, quantum] Method of transmission of ENERGY. Specifically, (1) any electromagnetic wave (QUANTUM), (2) any moving electron or nuclear particle, charged or uncharged, emitted by a radioactive substance, (3) acoustic pressure waves, and (4) GRAVITATION WAVE extension of gravitational attraction force through gravitational radiation. The elementary form of radiation is found as electromagnetic radiation, which is the result of an accelerated charge. The ELECTROMAGNETIC THEORY was delineated by JAMES CLERK MAXWELL (1831–1879) in 1861. The concept of electromagnetic radiation resulting from accelerated charges was described by JOSEPH LARMOR (1857–1942) in 1897. In 1903 ERNEST RUTHERFORD (1871–1937) and FREDERICK SODDY (1877–1956) realized that radioactive ELEMENTS (now known as isotopes; introduced by Francis William Ashton [1877–1945] in 1919) spontaneously transform from one chemical substance to another accompanied by the emission of radiation of particulate (e.g., electron [JOSEPH THOMPSON (1856–1940) 1897], PROTON [identified/postulated by WILHELM WIEN (1864–1928) in 1898, named by ERNEST RUTHERFORD in 1920], NEUTRON [discovered by JAMES CHADWICK (1891–1974) in 1932], helium ion: ALPHA PARTICLE) or electromagnetic radiation (e.g., X-RAY, gamma radiation, and visible LIGHT as well as INFRARED radiation). At the time of Rutherford’s and Soddy’s declaration, the ATOM concept was known, however, the NUCLEUS was not discovered as of yet. Natural ACTIVITY resulting in radiation is one mechanism, specific examples are uranium and thorium; artificial radiation is the result of

the application of an external source on a stable ELEMENT, such as the production of X-ray resulting from the impact of fast electrons on metals such as tungsten. Radiation can be classified in ionizing (PARTICLE, high-energy electromagnetic) and nonionizing (mid- to long-wave electromagnetic) (*also see WIEN'S DISPLACEMENT LAW, PLANCK'S RADIATION LAW, and RAYLEIGH-JEAN LAW*) (see [Figure R.4](#)).

Figure R.4 Radiation: (a) antennas with simulated electromagnetic radiation, (b) penetration for different types of radiation, and (c) radiation physics showing the properties of α , β , and γ radiations.

Radiation belt

[astrophysics/astronomy, general] Partial shell of charged particles in orbit around EARTH, maintained by the earth's MAGNETIC FIELD. Several radiation belts are suspected, but the Van Allen radiation belts are verified and well described (*see* VAN ALLEN RADIATION BELTS; *also see* AURORA BOREALIS [i.e., NORTHERN LIGHTS]) (*see* Figure R.5).

Figure R.5 Diagram of what a radiation belt around the Planet Earth may look like; with one of the consequences: the auroras.

Radiation coupling

[acoustics, optics] Coupling of acoustic or optical WAVE respectively. A principle that operates as a LINEAR FILTER which describes the transition between two lumped mechanical or optical components (*see* Figure R.6).

Figure R.6 Radiation coupling for acoustic waves. Relatively high-energy ultrasound is coupled into the skin for the disintegration of the mixture of fatty and connective tissue (e.g., collagen) in the treatment of cellulite. In order to avoid “burning” the skin a medium is applied between the transducer and the skin to maximize the transfer of acoustic energy to penetrate deep below the surface of the skin to perform the restructuring of the tissue based on radiation absorption at a location that is remote from the point of entry.

Radiation dose

[biomedical, nuclear] The emitted dose of PARTICLE and electromagnetic RADIATION resulting from ISOTOPE DECAY. The kind of radiation and respective ENERGY content will determine the biological impact, known as dosimetry and biological hazard. Radiation dose is generally measured in rem or millirem, accepted as a standard by the Nuclear Regulatory Commission (see DOSIMETRY; also see CARBON DATING) (see Figure R.7).

Figure R.7 Radiation dose meter, that is, Geiger counter, providing the exposure in Rads per hour.

Radiation force

[acoustics] Acoustic radiation force represents the interaction of an acoustic WAVE (longitudinal pressure wave) with an obstacle in its path. The MAGNITUDE of the FORCE (F) is directly correlated to the local AMPLITUDE (and respective intensity: I ; in $[\text{W}/\text{cm}^2]$) as $|F| = 2\alpha_{\text{abs}} I / v_s$, where v_s is the speed of SOUND in the medium with localized acoustic attenuation α_{abs} . The absorption coefficient is expressed in Neper per CENTIMETER (Np/cm) (see Figure R.8).

Figure R.8 Conceptual representation of solar wind, applying radiation force, acting on a long-range probe with large panels acting as solar sails. Note that for the solar radiation force to be effective the “sails” will need to be substantial since the effect is minimalistic, especially at expanding distance (diminished effect from the solar radiation pressure inversely proportional to the radius square).

Radiation hazards

[atomic, nuclear] Various kinds of radiation have different ENERGY content with specific biological and material consequences. The radiation ACTIVITY is one of the means of determining the potential for the energy content; disintegration rate. Another concept related to the energy content is the half-life. The originally adopted standard for radiation consequences is the number of ionizations produced by X-RAY or

gamma rays, since then replaced by the number of disintegrations per SECOND for a RADIOACTIVE ISOTOPE, measured in Becquerel ([Bq]). The biological damage potential is generally based on the ABSORBED DOSE, measured in Gray (old unit Rad). The risk for modifications to the genetic material: DNA, or causing burns resulting from a specific kind of exposure is expressed by the QUALITY FACTOR. The quality factor provides the dose equivalent exposure, which is a more quantifiable risk identifier for human risk. The quality factor (Q_r) for specific types of RADIATION is defined as follows: X-ray, gamma rays, and beta radiation $Q_r = 1$; high-energy photons have $Q_r = 10$; exposure to neutrons of unknown energy has a quality factor $Q_r = 10$; while ALPHA PARTICLES are considered to be the most hazardous with $Q_r = 20$. The following heuristic values for biological damage have been determined; absorbed dose and biological effect: 100 Gy results in virtually instantaneous death (hours); 12 Gy results in death within days; 6 Gy results in death within weeks; 1 Gy may be treated and the person may recover and survive (with residual biological damage); 0.5 Gy has no discernible biological effects; 0.25 Gy results in changes to the BLOOD structure; and at 0.05 Gy the first changes to blood are observed. Note that radiation exposure is cumulative. (Note: MARIE SKŁODOWSKA CURIE [1876–1934] suffered the consequences of her work with radiation, dying from radiation-inflicted damage to her biological functions.) In reference an average day yield exposure of 3 mSv/year; while a chest X-ray provides 6 mRem, and a lumbar spine CT 16 mSv. Background radiation exposure to every person on the PLANET results from the following sources: COSMIC RAYS; natural phenomena (e.g., ^{14}C {carbon dating} and radon); terrestrial sources (^{235}U); therapeutic devices (X-ray, etc.); various consumer products hold radioactive isotopes (e.g., tobacco: ^{210}Po ; welding rods: ^{222}Th ; certain mechanical watches have the dial “illuminated” by tritium or radium (old style); and smoke detectors: ^{241}Am), fall-out from nuclear weapons tests, radiation leaks from nuclear power plants; and the following sporadic and low importance (small MAGNITUDE) effects ISOTOPE research and AIR travel (*also see* RADIATION UNITS) (see Figure R.9).

Figure R.9 (a) Radiation hazard warning sign near a nuclear power station and (b) graphical representation of how high-energy radiation may modify the genetic structure, resulting in cancer and/or death. Section of the abandoned city of Pripyat near Chernobyl in Ukraine (then Russia; as a matter of fact: CCCP/USSR) after a nuclear meltdown in the nuclear power plant.

Radiation therapy

[biomedical, energy, thermodynamics] Clinical, therapeutic procedures involving various types of RADIATION: charged particles (e.g., protons and electrons), X-RAY, and gamma rays to selectively cause the eradication of undesirable cells, specifically malignant cells of tumor structures. The radiation may be applied externally or internally. The external radiation is provided by specialized devices, whereas the internal radiation may be provided either from a confined RADIOACTIVE ISOTOPE (brachytherapy) or from the systemic release from an ISOTOPE introduced by ingestion or injection (e.g., radioactive iodine). The mechanism of action of generating CELL death as a therapeutic goal is in the restructuring of DNA form

external to the cell, or by means of creating secondary free radicals inside the cell without actual penetration subsequently resulting in cell death. The treatment of hypo- or hyper thyroidism by means of radioactive iodine is one of the most common and well-known methods. The thyroid treatment is relatively selective due to the affinity of the thyroid for iodine. Most cancer treatments are not selective about the targeted cells, and subsequently have a consequence of damaging and killing healthy cells as well, specifically in the direct vicinity of the tumor during external radiation, but more systemic (whole body) for isotope reagents released in the bloodstream (primary) or ingested for absorption in the BLOOD stream through the digestive system (secondary system). Radiation therapy may also be used for benign cancer when the cancer is causing secondary effects, for instance, causing pressure on vital organs due to the rapidly expanding cell volume, such as esophagus and spine. Therapeutic radiation to the brain may destroy the brain but the metastases of cancer spreading into the brain can potentially be regressed by radiation. One particularly specific and selective external means of radiation therapy is currently achieved by the CyberKnife. Brachytherapy may require special tools, such as catheters and needles and nanoparticles (see [Figure R.10](#)).

Figure R.10 Patient undergoing radiation therapy.

Radiation units

[atomic] The number of decaying nuclei per unit of time (disintegrations per SECOND) is measured in Becquerel ([Bq]; SI unit), alternatively the Curie is also found: $1 \text{ Ci} = 3.7 \times 10^{10} \text{ Bq}$. The ENERGY of radiation is measured in electronvolt, ([eV]); the energy of an electron under a potential difference of 1 V. Examples are the electrons emitted from the carbon ISOTOPE ^{14}C have an energy of $157 \text{ keV} = 0.157 \text{ MeV}$ (beta radiation); gamma radiation from cesium (^{137}Cs) has an energy of 662 keV , and alpha radiation from Americium (^{241}Am) has an energy of 5.485 MeV . The ABSORBED DOSE is measured in Gray ([Gy]); old unit Rad. The conversion from Rad to Gray is $1 \text{ Rad} = 0.01 \text{ Gy}$. The exposure is measured in Coulombs per kilogram (SI: [C/kg]), with the old unit the Röntgen ([R]). The conversion equivalence from the Röntgen is $1 \text{ R} = 2.58 \times 10^{-4} \text{ C/kg}$. The dose equivalent has the quantity in Sievert (SI: [Sv]), while the old unit is Rem.

The Rem converts to the Sievert as $1\text{ Rem} = 0.01\text{ Sv}$. The “dose equivalent” exposure incorporates the type of radiation, expressed by the **QUALITY FACTOR**. The dose equivalent is a more quantifiable risk identifier for human risk (for instance, resulting in modifications to the genetic material: DNA, or causing burns) from exposure. For X-RAY RADIATION one Röntgen of radiation is approximately equivalent to 1 Rad with respect to human tissues. Under the old units gamma radiation yields $1\text{ R} \cong 1\text{ Rad} \sim 1\text{ Rem}$ (see [Figure R.11](#)).

Radiation activity units of measure

- The number of decaying nuclei per unit of time
- The Système International (SI) unit of radioactivity is the becquerel (Bq)
 - One Bq = 1 disintegration per second
- Non-SI unit of radioactivity is the Curie (Ci)
 - One Ci = 3.7×10^{10} transformations per s
 - One millicurie (mCi) = $3.7 \times 10^7 \text{ s}^{-1}$
 - One microcurie (μCi) = $3.7 \times 10^4 \text{ s}^{-1}$
 - $1 \text{ Bq} = 2.7 \times 10^{-11} \text{ Ci}$

(a)

Quantities and units

Quantity	Conventional	SI
Exposure	roentgen (R)	coulomb/kg
Absorbed dose	rad	gray (Gy)
Dose equivalent	rem	sievert (Sv)

(b)

Activity

- Activity is the number of transformations (or disintegrations) per time occurring in a radioactive material
- Conventional unit: curie (Ci)
 - $1 \text{ Ci} = 3.7 \times 10^{10}$ disintegrations per second
- International System (SI): Becquerel (Bq)
 - $1 \text{ Bq} = 1$ disintegration per second
- $1 \text{ Ci} = 3.7 \times 10^{10} \text{ Bq}$

(c)

Activity—units: conventional vs. SI

Conventional system	SI system
• $1 \text{ milliCi} = 1/1000 \text{ Ci}$	• $1 \text{ kiloBq} = 1000 \text{ Bq}$
• $1 \text{ microCi} = 1/1,000,000 \text{ Ci}$	• $1 \text{ megaBq} = 1,000,000 \text{ Bq}$
• $1 \text{ kiloCi} = 1000 \text{ Ci}$	• $1 \text{ gigaBq} = 1,000,000,000 \text{ Bq}$
• $1 \text{ megaCi} = 1,000,000 \text{ Ci}$	

(d)

Energy units for measuring radiation

Radiation energies are typically measured in units of keV (1000 electron volts) or MeV (million electron volts)

Examples:

C-14 beta 0.157 MeV or 157 keV

Cs-137 gamma 662 keV

Am-241 alpha 5.485 MeV

(e)

Figure R.11 (a–e) Radiation unit configuration.

Radiative capture

[atomic] Capture of a low-energy proton (p) or NEUTRON (n) by the atomic nucleus, transforming the NUCLEUS into a RESIDUAL NUCLEUS in a highly excited state. The capture PARTICLE may not be expelled, leaving the nucleus to emit the excess ENERGY as gamma radiation (γ), while changing the ISOTOPE value. An example is the conversion of magnesium to aluminum through proton capture: $^{26}\text{Mg} + p \rightarrow ^{26}\text{Al} + \gamma$. Eventually, the (unstable) converted state will regress to the “GROUND” state when bombarded by gamma radiation during a process called PHOTODISINTEGRATION: $^{26}\text{Al} + \gamma \rightarrow ^{26}\text{Mg} + p$ (see Figure R.12).

Figure R.12 Example of the process with respect to radiative capture for a neutron.

Radiative power

[biomedical, general] ENERGY transfer from one location to another. Calculated by the number of photons per SECOND ($\dot{n}$) at wavelength λ this yields: $P_{\text{radiative}} = (\dot{n}h/\lambda)c$, where with $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK'S CONSTANT, and $c = 2.99792458 \times 10^8 \text{ m/s}$ the speed of LIGHT. Also known as RADIANT FLUX.

Radiative transfer

[astrophysics/astronomy, biomedical, energy] The transfer of ENERGY through the medium of electromagnetic RADIATION, also known as the radiative transfer equation (see EQUATION OF RADIATIVE TRANSFER).

Radio

[electronics, general] Device for receiving radio waves, which are emitted from radio stations. Sometimes also referring to the functional unit emitting the radio waves, the RADIO STATION (building with record players). Radio is subdivided in AMPLITUDE MODULATION (AM) and frequency modulation (FM). AM RADIO waves imply a perturbation applied to a CARRIER WAVE, where the perturbation encodes a selected portion of the audible frequency range (20 Hz–20 kHz), AM radio does not provide STEREO reception. In FM electromagnetic transmissions, the frequency of the carrier WAVE is changed within a narrow band to provide encoded embedded signals that can be decoded at the radio receiver. AM stations can be subdivided into short waves and long waves; operate in the frequency range 153 kHz to 26.1 MHz. Specifically, AM radio as found on the receiver operates from 535 to 1605 kHz. Long-wave radio SIGNAL as well as most AM signals across the frequency band will reflect off the IONOSPHERE, resulting in a long span of reception, long-wave radio specifically (153–279 kHz) can be received from the opposite side of the world under the appropriate weather conditions. FM radio primarily relies on line-of-sight reception (the tip of the ANTENNA is in theoretical view by the receiving location), this can extend in a flat topography for the geographic location for up to 30 km (primarily as a function of the radiant power supplied by the emitting station), apart from SATELLITE

transmission. FM radio generally operates in the frequency range 88–108 MHz. Due to the intricate process of FM and decoding process at the receiver, two signals can be transmitted simultaneously, offering stereo audio when two separate SPEAKER units are available and attached to the radio entity (see [Figure R.13](#)).

Figure R.13 (a) Analogue radio, showing the various wavebands: short wave (SW), medium wave (MW), long wave (LW), and frequency modulated (FM) and (b) analog radio display tuning panel which includes ultrashort wave band (UKW), primarily used in FM transmission.

Radio frequency (RF)

[biomedical, electronics] EMISSION SPECTRUM with the electromagnetic phenomenon. Radio frequency is in the wavelength range beyond INFRARED and microwave and in the same spectrum as RADIO and television waves, while shorter in wavelength than alternating power supplies/generators. The established spectral range is 3 kHz to 300 GHZ, where the high frequencies generally fall under microwave, it may still qualify as radio frequency. The Federal Communications Commission classifies radio frequency as the range of 9 to 275 kHz. Radio frequency RADIATION can be transmitted through cable more easily than the shorter wavelengths in the MICROWAVE regime, and is used for interstitial heat in biological therapeutic applications to provide elevated temperature-induced CELL death. Radio frequency is also used for navigation purposes as well as wireless communication (see [Figure R.14](#)).

Figure R.14 Radio frequency: radio-controlled remote operating helicopter.

Radio receiver

[general] There is a fundamental difference between analog and digital RADIO signal production and reception. The mechanism of action in analog modulation is continuous frequency modulation. In digital electromagnetic transmission and reception the encoding and decoding will still occur at the principal frequency, but the encoding will involve discrete pulse trains. With current technology the use of digital

mechanisms are more prevalent due to the reduced risks for distortion and NOISE compared to analog SIGNAL processing (*see* RADIO) (*see* [Figure R.15](#)).

Figure R.15 Radio receiver. Edwin Howard Armstrong (1890–1954) and his wife Esther Marion MacInnis on the beach with the “portable” radio designed and built for his wife, on Palm Beach, Florida, in 1923. The radio was Edwin Armstrong’s portable superheterodyne. Earlier “portable radios” are on record.

Radio station

[electronics, general] Building with record players, CD-players (MP3, MP4, etc.), digital storage devices (computer hard drives, memory sticks, etc.), and one or more microphones, that are connected electronically to an encoding device that embeds the audio signals in electromagnetic RADIATION that is conveyed to an ANTENNA that radiates the electromagnetic SIGNAL in all directions; alternatively routed to SATELLITE stations for satellite transmission. The first RADIO operation was in 1906, only AM. The FM radio principle was patented in 1933 by Edwin Howard Armstrong (1890–1954), an electrical engineer from the United States, followed in 1937, the first experimental radio station (W1XOJ) in the United States providing the first frequency modulated radio transmission, followed in 1948 with FM TRANSMISSIONS in Germany under newly implemented waveband plans. In 1958 English radio transmissions were experimentally used for STEREO transmissions. Note that the first two-channel audio system had already been introduced in 1881 by Clément Ader (1841–1925) in Paris (*see* [Figure R.16](#)).

Figure R.16 Example of a radio station in the United States.

Radioactive decay

[atomic, computational, energy, general, nuclear] Radioactive decay will depend on the original state of the ISOTOPE or unstable NUCLEUS. The determining factor is relying on PROTON or NEUTRON deficiency. The kinds of DECAY recognized are the following. ALPHA PARTICLE decay [α], the PARTICLE emitted during decay resembles a helium nucleus consisting of two neutrons and two protons: ${}^A_ZX \rightarrow {}^{A-4}_{Z-2}Y + {}^4_2\text{He}$. The second form is BETA PARTICLE decay [β^-]: ${}^A_ZX \rightarrow {}^A_{Z+1}Y$, where the beta particle is in all characteristics identical to an electron. The other mechanism of decay is represented by beta-plus radiation (also referred to as positron emission) [β^+]: ${}^A_ZX \rightarrow {}^A_{Z-1}Y$. Gamma radiation is another form of radioactive decay due to annihilation, where a positron (beta-plus particle) and an electron (equivalent beta particle) collide and form a pair of gamma photons that are emitted at perfectly opposite directions. Each gamma PHOTON has an ENERGY of 0.511 MeV. ELECTRON CAPTURE is a form of RADIATION where an electron is captured by an unstable nucleus that does not have enough energy to spontaneously decay by positron emission. The convergence of a proton and the captured electron are transformed into a neutron and a NEUTRINO: $p_{\text{proton}} + e^- = n_{\text{neutron}} + \bar{\nu}$. The resulting vacancy in the electron shell will result in X-RAY emission. The CHARACTERISTIC X-RAY radiation associated with the removal of the electron will with great PROBABILITY come from K-shell decay. In the electron capture process gamma radiation may also occur. In certain cases, depending on the energy configuration the release of gamma energy will be captured by an orbital electron, which is internally released, indicated by the mechanism of action of INTERNAL CONVERSION (see Figure R.17).

Figure R.17 Radioactive decay example.

Radioactive decay chain

[nuclear] RADIOACTIVITY was discovered by ANTOINE HENRI BECQUEREL (1852–1908) in 1896, but the phenomenon was named by MARIE SKŁODOWSKA CURIE (1876–1934) around 1903. Chain of discrete isotopes that are formed during the RADIOACTIVE DECAY process. The chain represents the series of events and

product from naturally radioactive of artificially produced RADIOACTIVE ISOTOPE to the final stage over the extended time duration of the cumulative half-life intervals of all the intermediate steps (see Figure R.18).

Figure R.18 Radioactive decay chain.

Radioactive decay constant (λ_{decay})

[atomic, nuclear] Constant indicating the rate of isotope DECAY, representing the proportional reduction in ISOTOPE (N_{isotope}) with respect to the original quantity, or ACTIVITY at initiation of isotope (N_0) over time of activity (t): $dN = -\lambda_{\text{decay}} N dt$, or $N(t) = N_0 e^{-\lambda_{\text{decay}} t}$. The HALF-LIFE (τ_{decay} , also found as $T_{1/2}$) of the isotope follows directly from the time lapse to decay to half the original quantity $N(\tau_{\text{decay}}) = (1/2)N_0$, yielding $\tau_{\text{decay}} = T_{1/2} = \ln 2 / \lambda_{\text{decay}} = 0.693 / \lambda_{\text{decay}}$ (see Figure R.19).

Figure R.19 Graphical interpretation of the radioactive decay constant in the time lapse for disintegration.

Radioactive decay law

[atomic, biomedical, energy, nuclear] *see* RADIOACTIVE DECAY CONSTANT *and* RADIOACTIVE TRANSFORMATION.

Radioactive isotope

[atomic, nuclear] Atom with identical chemical behavior as a known ELEMENT but with a different mass. Isotopes are generally radioactive with an associated half-life. The most well-known radioisotope is carbon-14, the ISOTOPE of carbon-12. Carbon-14 occurs naturally in all carbon-based life forms due to the chemical exchange during the lifetime of the biological entity, for example, consumption of carbohydrates. Carbon-14 is specifically known for determination of the AGE of the “deceased” biological object, based on the RADIOACTIVE DECAY. The half-life of ^{14}C is 5,730 years with electron emission, which limits the use for age determination to approximately 50,000 years; with potential enhancements in the detection technique stretching the span to 100,000 years (e.g., accelerator technique). The ratio of ^{14}C to ^{12}C is a relative constant at 1.3×10^{-12} in a living environment. Other examples of naturally occurring isotopes, with respective HALF-LIFE ($\tau_{1/2}$) and decay process are uranium-238, $\tau_{1/2} = 4.5 \times 10^9$ years, alpha-particle (α_d); tritium-3, $\tau_{1/2} = 12.26$ years, ELECTRON (e^-); cobalt-60, $\tau_{1/2} = 5.24$ years, e^- ; iodine-131, $\tau_{1/2} = 8$ days, e^- ; and radon-222, $\tau_{1/2} = 3.82$ days, α_d . It is also known as RADIOISOTOPE, or ISOTOPE (see Figure R.20).

Figure R.20 Carbon isotopes.

Radioactive transformation

[atomic, nuclear] The random process of nuclear transmutations of ELEMENT, subject to the WEAK FORCE. The transformation process can be expressed as a STOCHASTIC PROCESS describing the overall likelihood of the occurrence of a change in elemental structure over TIME (t) expressed as $N(t) = N_0 e^{-t/\tau_{1/2}}$, with $\tau_{1/2}$ the RADIOACTIVE DECAY half-life, and N_0 the initial quantity of radioactive material; known as the LAW OF RADIOACTIVE TRANSFORMATION. The following transformation processes are available: ELECTRON DECAY, POSITRON DECAY, ALPHA DECAY, gamma decay, orbital ELECTRON CAPTURE, nucleon energy transfer to GROUND STATE, INTERNAL CONVERSION (NUCLEON to electron), next to spontaneous FISSION, double BETA DECAY (specifically related to ^{92}Mo and ^{100}Mo), and cluster decay (*see* RADIOACTIVITY).

Radioactive waste

[atomic, nuclear] Refuse resulting from the commercial use of radioactive isotopes. Radioactive waste is produced by hospitals during cancer therapy, in the production of several consumer goods and the generation of ELECTRICITY by means of nuclear power plants. A byproduct of coal burning factories is slurry (ash) that is also radioactive due to the uranium and thorium content in coal (see [Figure R.21](#)).

Figure R.21 Radioactive waste handling and disposal.

Radioactivity

[atomic, nuclear, quantum] The process whereby certain nuclides undergo spontaneous atomic disintegration in which ENERGY is liberated, generally resulting in the formation of new nuclides. The process is accompanied by the emission of one or more types of RADIATION, such as ALPHA PARTICLES, BETA PARTICLES, and gamma radiation (*also see URANIUM and ISOTOPE*) (see [Figure R.22](#)).

Figure R.22 Some commonly occurring low-level emission radioactive consumer goods.

Radioastronomy

[astrophysics/astronomy, atomic] Branch of astronomy that uses the coherent aspects of electromagnetic RADIATION from galactic bodies for identification and determination of location. Generally, the sensing mechanism involves a RADIO telescope arranged in an INTERFEROMETER setting. Next to several multi-dish ANTENNA stations in discrete locations all over the world, the independent locations are collaborating to form a global-sized interferometer. One of the independent antenna arrays is the very large array on the plains of San Agustin, between the towns of Datil and Magdalena in New Mexico, consisting of 27 antennas, each

with a diameter of 25 m, configured in a Y-setting with arm length of 21 km. The very large array has a spatial RESOLUTION of 0.08 arcsec (see [Figure R.23](#)).

Figure R.23 Examples of radio telescopes searching the universe for radiographic (electromagnetic) information about structural composition of remote galactic objects next to potential radio emissions from artificial sources indicating the existence of extraterrestrial life. In the United States, the search for extraterrestrial life is categorized under SETI: search for extraterrestrial intelligence, in which the United States is executed by groups at, for instance, Harvard University, Cambridge, Massachusetts; the University of California, Berkeley, California, and the SETI Institute in Mountain View, California.

Radiography

[imaging] Transcorporeal imaging technique using X-RAY RADIATION. It is also known as radiographic analysis and radiography imaging (*also see CT-IMAGING and X-RAY IMAGING*) (see [Figure R.24](#)).

Figure R.24 Extra-oral radiographic view showing the placement and outline of the teeth, sometimes to be used for identification purposes. Sometimes also referred to as fluoroscopy, based on the scintillation elements recording the transmitted X-ray radiation and converting it in electromagnetic radiation that can be detected by electronic sensor units. The collected signals as a function of location and time of detection are ordered by computational techniques to render a reconstructed image based on attenuation for line of flight.

Radioisotope

[atomic, biomedical, general, nuclear] *See* ISOTOPE.

Radionuclide

[atomic, biomedical, nuclear] *See* NUCLIDE.

Radiopharmaceutical

[biomedical, chemical] RADIOACTIVE ISOTOPE used for tagging and imaging of physiological and anatomical features and phenomena, primarily applied in positron emission TOMOGRAPHY. One of the most used radiopharmaceuticals is fludeoxyglucose (FDG: $C_6H_{11}^{18}FO_5$) used in gauging the METABOLIC ACTIVITY related to cancer, HEART disease as well as epilepsy due to its equivalence with standard dietary GLUCOSE (see Figure R.25).

Figure R.25 Chemical diagram of radiopharmaceutical: fludeoxyglucose ^{18}F .

Radium ($^{226}_{88}Ra$)

[atomic, general, nuclear] Radioactive ELEMENT discovered by MARIE (MANYA) SKŁODOWSKA CURIE (1867–1934) and her husband PIERRE CURIE (1859–1906) approximately in 1902. Radium, generally found in the GROUND, decays to radon in the ground.

Radius of gyration (R_g)

[atomic, biomedical, fluid dynamics, solid-state] Parameter used to describe the characteristic dimension that apply to a POLYMER chain in polymer PHYSICS, defined as

$$R_g = \sqrt{\left[(1/n) \sum_{i=1}^n (r_i - r)^2 \right]} = \sqrt{\left[(1/2n^2) \sum_{i,j}^n (r_i - r_j)^2 \right]},$$

where r_i signifies the DISTANCE to the “central axis” of the polymer; representing the center of mass as a function of longitudinal location for location i , and r the mean radius to the central axis for the collective assembly of monomers; also with respect to the interspatial distance for the respective monomers (defined in the root mean square for $r_i - r_j$). Alternatively, in fluid-dynamic applications of buoyance the radius of gyration signifies the configuration of a floating object, given by the root mean square distance for a representative number of locations on the surface of the objects and associated parts with respect to the CENTER OF GRAVITY over the length of the object: $R_g = \sqrt{(I/A)}$, where I is the MOMENT OF INERTIA of the object in the direction of roll (predominantly perpendicular to the long axis of the body), and A the surface area of the buoyant object under the LIQUID surface.

Radon ($^{222}_{86}\text{Rn}$)

[atomic, general, nuclear] Radioactive ELEMENT formed by ALPHA DECAY of radium. Radon GAS is often found in the basement of houses due to the way radon is formed in the GROUND. Radon radiates by alpha decay and provides approximately 55% of all background RADIATION (see [Figure R.26](#)).

Figure R.26 The element radon and the theoretical electron configuration.

Rain

[energy, fluid dynamics, general, geophysics] Precipitation in LIQUID form, droplets of condensate water from clouds; the condensate water VAPOR reaches a volume that becomes subject to gravitational attraction, overcoming the BUOYANCY (see [Figure R.27](#)).

Figure R.27 Liquid precipitation.

Rain gauge

[energy, fluid dynamics, general, geophysics] Device used to determine a physical phenomenon in the lower part of EARTH'S ATMOSPHERE directly related to LIQUID precipitation (see [Figure R.28](#)).

Figure R.28 Rain gauge.

Raisin-pudding atom

[general] See **BOHR ATOM MODEL**.

Raman, Chandrasekhara Venkata, Sir (1888–1970)

[energy, optics] Indian scientist and philosopher. Sir Raman received Nobel Prize for Physics with regard to his work on the molecular SCATTERING of LIGHT in 1930. In 1921 Professor Chandrasekhara V. Raman and his students discovered that an incident light beam transmitted through a LIQUID resulted in a spectrum that not only included the original light but also secondary radiation at shifted wavelengths. The original experimental setup passed sunlight through an optical filter to produce a polarized incident light beam that was then transmitted through the sample material. The emerging scattered light beam was then passed through a second optical filter and the resulting spectrum was observed visually. From these initial experiments it was determined that the intensity of the resulting secondary RADIATION was dependent on both the frequency and the POLARIZATION of the light beam incident to the sample (see [Figure R.29](#)).

Figure R.29 (a,b) Sir Chandrasekhara Venkata Raman (1888–1970).

Raman scattering

[nuclear, optics, solid-state] Inelastic SCATTERING of photons, first described in a LIQUID turbid medium by SIR CHANDRASEKHARA VENTAKA RAMAN (1888–1970) and Kariamanickam Srinivasa Krishnan (1898–1961) in liquid in 1921. The effect was confirmed for scattering in crystals by Grigory Samuilovich Landsberg (1890–1957) and Leonid Isaakovich Mandelshtam (1879–1944) in 1928. In contrast to ELASTIC SCATTERING, where the ENERGY is conserved, in Raman scattering portion of the PHOTON energy is transferred to the molecular bindings, thus revealing details about the energy of the atomic–molecular structure based on the emitted INFRARED spectrum. For the constituents of a CHEMICAL COMPOUND with N atoms, there are a total of $3N$ DEGREES OF FREEDOM with respect to rotation, stretch, and bend (scissor action) for the motions of the MOLECULE. For a linear molecule the total number of vibrational modes is $3N-5$, whereas for a complex structure the vibrational modes add up to $3N-6$. This principle is applied to gas CHROMATOGRAPHY for molecular analysis. The spectral profile will be composed of Rayleigh scatter, Stokes and anti-Stokes scatter frequency shifts (cm^{-1} scale), and is referred to as the Raman spectrum. The shifts in spectral peaks are indications of the energy changes with respect to GROUND STATE of the molecule, and define the BINDING ENERGY profile and can be used to identify the chemical structure with the help of look-up tables.

Also known as the Raman effect. Also described as RAMAN SPECTROSCOPY with respect to the physical detection of the transition processes (see [Figure R.30](#)).

Figure R.30 (a,b) Raman scattering and associated Raman spectroscopy. The Raman spectrum is composed of sharp and narrow peaks. The peaks are on either side of the excitation line resulting from laser irradiation (excitation). The peaks are referred to as Stokes and anti-Stokes lines. The graph represents the Stokes and anti-Stokes Raman spectral lines for the chemical compound CCl_4 , under excitation irradiation by a 514.5 nm argon ion laser line. The frequency differences between the excitation radiation and the Raman scattered radiation are called the Raman shift. Raman shifts are reported in units of wavenumber (cm^{-1}) and are defined by the Raman shift: $\Delta = (1/\lambda_0) - (1/\lambda_R)$ [cm^{-1}] resulting from laser irradiation with wavelength λ_0 , with the resulting Raman radiation at wavelength: λ_R .

Raman spectroscopy

[atomic, nuclear, optics] See **RAMAN SCATTERING**. Also known as **RAMAN SPECTRA**.

Ramsay, William Mitchell, Sir (1852–1916)

[general] Scientist from Scotland (Great Britain), known for his discovery of helium on EARTH, specifically in uranium bearing minerals as well as the description of noble gases (inorganic chemistry) starting in approximately 1885. His work and the work of **FREDERICK SODDY** (1877–1956) showed that the helium originated from radium, produced in a **DECAY** process. They however did not describe the atomic structure of helium just yet. Sir Ramsay received the Nobel Prize in Chemistry for his work on noble gases in 1904. Sir Ramsay discovered and defined argon, helium, krypton, neon, and xenon (see [Figure R.31](#)).

Figure R.31 Sir William Mitchell Ramsay (1852–1916).

Random walk

[biomedical, computational] Stochastic principle in discrete PROBABILITY distribution with respect to the SCATTERING of photons in a turbid medium such as tissue. The concept of random walk is most frequently approached through computer simulation mechanisms using a principle called “Monte Carlo” analysis, relying on a probability distribution of the scattering events in this case using THEORY OF LARGE NUMBERS. Compare to FINITE ELEMENT ANALYSIS (see [Figure R.32](#)).

Figure R.32 Representation of the principle of random walk (a) in two-dimensional projection for 5 photons and (b) for three events (e.g., photons, molecules, etc.) in three-dimensional diagram, generated by means of computer simulated ray-tracing.

Rankine

[biomedical, thermodynamics] Unit of measure of ABSOLUTE TEMPERATURE designed by WILLIAM RANKINE (1820–1872). In comparison the Kelvin and degrees Celsius are relative scales.

Rankine, William John Macquorn (1820–1872)

[general, solid-state, thermodynamics] Scottish scientist (physicist/engineer), who made significant contributions to the development of the thermodynamic theoretic base (see [Figure R.33](#)).

Figure R.33 William John Macquorn Rankine (1820–1872). (Courtesy of University of Glasgow, Glasgow; “Memorials of the Old College of Glasgow”—http://encore.lib.gla.ac.uk/iii/encore/record/C__Rb1168827?lang=eng.)

Rankine cycle

[thermodynamics] Process that is fundamentally reversible pertaining to the temperature-specific entropy loop for a system of bulk flow states. The process consists of four segments; the first segment is isobaric heating, followed by an **ISENTROPIC** interval of **EXPANSION** to the two-phase system, the third segment involves the isobaric condensation under constant temperature, with the final stage returning to the original format under isentropic compression under **MECHANICAL ENERGY** resulting from the compression by piston with work rate $\dot{W}_c^{\leftarrow}$. The efficiency (η_{eff}) of the Rankine cycle is a function of the specific enthalpy (h_i) of the

various stages (4) in the process: $\eta_{\text{eff}} = \left[(h_4 - h_5) - (h_1 + h_6) \right] / (h_4 - h_1) = 1 - \left[(h_5 - h_6) / (h_4 - h_1) \right]$, introduced based on the work of WILLIAM RANKINE (1820–1872) (see Figure R.34).

Figure R.34 Graphical representation of the Rankine cycle.

Rankine–Hugoniot equations

[fluid dynamics] Equation describing the physical properties during a SHOCK WAVE propagating with shock WAVE velocity v_s , undergoing volumetric changes (specific volume V_{sp}), and velocity of the mechanism of expansion (e.g., piston, breaking plate, moving surface) v , with $\square_0$ describing the initial state, pertaining to CONSERVATION OF MASS: $(V_{\text{sp},0} - V_{\text{sp}})/V_{\text{sp},0} = (v - v_0)/v_s$; as well as the conservation of momentum under PRESSURE (P) change: $P - P_0 = v_s \left[(v - v_0)/V_{\text{sp},0} \right]$; and the CONSERVATION OF ENERGY, where the EXPANSION provides kinetic ENERGY (KE), combined with the potential energy (U) as total energy (E): $E - E_0 = (V_{\text{sp},0} - V_{\text{sp}})(P + P_0)/2$. The Rankine–Hugoniot equations define the respective final states of the shock compression for the medium with an initial state. The graphic representation of the pressure versus the volume for the shock wave is referred to as the “Hugoniot.” With the use of the Rankine–Hugoniot equations the shock wave can be determined when the initial conditions are known and any two of the other five components in the equation can be measured. The expansion velocity is most commonly measured. Related to the shock wave the following relationships apply. For the expansion the correlation to the MACH NUMBER (M), SPECIFIC HEAT (c_p ; respectively c_v), and respective specific heat ration: $\gamma_s = c_p/c_v$, provides $P/P_0 = \left[2\gamma_s M^2 - (\gamma_s - 1) \right] / (\gamma_s + 1)$. For the specific volume this yields $V_{\text{sp}}/V_{\text{sp},0} = \left[(\gamma_s - 1)M^2 + 2 \right] / \left[(\gamma_s + 1)M^2 \right]$. Whereas the IDEAL GAS LAW provides the TEMPERATURE (T) relation during a shock-wave as $T/T_0 = PV/P_0V_0$.

Raoult, François-Marie (1830–1901)

[chemical, thermodynamics] A chemist from France. François-Marie Raoult defined the MIXING of gases (and this may under strict conditions also apply to solutions) as RAOULT'S LAW. Additional work by Raoult described the lowering of the freezing point (T_{freeze}) as a result of adding a SOLUTE to a LIQUID, proportional to the molecular concentration: $T_{\text{freeze}} = M\mathcal{A}_{\text{temp}}$, where M is the MOLECULAR WEIGHT of the dissolved component and $\mathcal{A}_{\text{temp}}$ the molecular lowering of the FREEZING temperature; sometimes referred to as the general law of the freezing of solutions (see [Figure R.35](#)).

Figure R.35 François-Marie Raoult (1830–1901). (Courtesy of Zeitschrift für Physikalische Chemie, Vol. 27, 1898.)

Raoult's law

[thermodynamics] The partial VAPOR PRESSURE for each of the components in a mixture is equal to the vapor pressure of the individual constituent at that temperature multiplied by the respective MOLE fraction in the mixture. Introduced by FRANÇOIS-MARIE RAOULT (1830–1901) in 1882.

R

Rapid prototyping

[biomedical, general, mechanics] The process of “printing” a three-dimensional design with composite material in a rapid process without the requirements for a mold, such as those used in injection molding, generally based on a Voxel-based construction using incremental steps of micrometers or millimeters; however, single molecular construction is also being developed for medical device and nanoscale intervention. Rapid-prototyping uses computer aided design (CAD-drawings) as the input for the process to “write” the construction in a stereolithographic format. The composite material is selectively positioned in pre-designated locations in three-dimensional space and cured by a process that depends on the material choice, sometime requiring laser LIGHT, sometimes OXIDATION or EVAPORATION by means of outside AIR. Rapid prototyping is used to create either scale models for show-and-tell or full-sized working devices, on small profile, in mass production up to several CENTIMETER in size. The size of rapid-prototyping designs is rapidly increasing to construct devices in meter size and larger. Several different techniques are available, ranging from laser sintering to epoxy molding. The initial introduction of rapid-prototyping was in the late 1980s. Also known as 3D printing, since the process has outgrown the “prototyping” stage. This rapid-prototyping is gently replacing computer NUMERICAL control machining since composite materials are approaching and exceeding METAL strengths (see [Figure R.36](#)).

Figure R.36 Rapid prototyping machine made out of LEGO® bricks, fully functional, connected to a computer and supplied with polymer substrate.

Rarefaction

[general] Reduction in molecular or PARTICLE density, or alternatively for a solid in space this may equate to an EXPANSION of the material, respectively stretch of a spring. Opposite of compression. For gases rarefaction is the opposite to condensation (see [Figure R.37](#)).

Figure R.37 Rarefaction.

Rasmussen, John (1926–)

[nuclear] Chemist from the United States. John Rasmussen provided significant details to the understanding of the nuclear structure from both experimental and on theoretical basis (see [Figure R.38](#)).

Figure R.38 John Rasmussen (1926–).

Rayleigh, Lord, a.k.a. John William Strutt (1842–1919)

[general, optics] Scientist from Great Britain. Lord Rayleigh's work describes the interaction of LIGHT with small particles, providing scattering at wavelengths generally smaller than the PARTICLE size. The Rayleigh scattering explains the spectral profile for the colors of the sky with respect to the position of the SUN and the pollutants and water droplet size in the ATMOSPHERE. The work of Lord Rayleigh was based on the experimental observations from JOHN TYNDALL (1820–1893), resulting is the RAYLEIGH SCATTERING theory in 1871. The Rayleigh scattering theory compares to the MIE SCATTERING from long wavelengths, described by GUSTAV MIE (1868–1957) in 1908 (see [Figure R.39](#)).

Figure R.39 Lord Rayleigh, a.k.a. John William Strutt (1842–1919).

Rayleigh criterion

[acoustics, optics] The angular separation ($\sin \theta \cong \theta$) that allows for independent recognition of two closely spaced objects or LIGHT sources (primary or secondary) as a function of wavelength (λ) as observed through an APERTURE with diameter D defined as $\theta = 1.22(\lambda/D)$, with corrections for edge effect of a circular opening ($\theta = \lambda/D$ for straight edges) (see **ABBE CRITERION** and **AIRY DISK**) (see [Figure R.40](#)).

Figure R.40 Rayleigh criterion.

Rayleigh emission law

[general, optics] Black-body RADIATION as a function of wavelength (λ) or FREQUENCY (ν): $I_{\nu,T}(T, \nu) = (2\pi c/\lambda^4) k_b T = (2\pi \nu^2/c^2) k_b T$, where $\lambda = c/\nu$ is WAVELENGTH, ν the frequency, c the speed of LIGHT, k_b is the BOLTZMANN CONSTANT, T the TEMPERATURE (in Kelvin). Also known as the Rayleigh–Jeans emission Law (see [Figure R.41](#)).

Figure R.41 Rayleigh (Rayleigh–Jeans) emission law.

Rayleigh flow

[fluid dynamics, thermodynamics] Flow condition with respect to adiabatic flow in a tube with constant cross-sectional area under flow velocity approaching or exceeding the MACH NUMBER. The flow under these conditions is subject to the stagnation temperature (T_s) and the Mach number (Ma) changes as described by $dM^2/M^2 = \left[\frac{(1 + \gamma_s Ma^2)}{(1 - Ma^2)} \right] \left(1 + \left[\frac{(\gamma_s - 1)}{2} \right] Ma^2 \right) (dT_0/T_0)$, where $\gamma_s = c_p/c_v$ is the SPECIFIC HEAT ratio; for the specific heat (c_p at constant pressure; respectively c_v at constant volume). The associated change in ENTROPY (S) is $\Delta S = \Delta s/c_p = \ln \left\{ Ma^2 \left[\frac{(\gamma_s + 1)}{(1 + \gamma_s Ma^2)} \right]^{(\gamma_s + 1)/\gamma_s} \right\}$, which is frequently plotted against the dimensionless entropy ($H = b/b^*$, with entropy at static temperature b^*), which yields the RAYLEIGH LINE.

Rayleigh line

[fluid dynamics, thermodynamics] Graphical representation of a flow condition with respect to adiabatic flow in a tube with constant cross-sectional area represented the enthalpy (S , respectively change: ΔS : $\Delta S = \Delta s/c_p = \ln \left\{ Ma^2 \left[\frac{(\gamma_s + 1)}{(1 + \gamma_s Ma^2)} \right]^{(\gamma_s + 1)/\gamma_s} \right\}$; see RAYLEIGH FLOW plotted against the dimensionless entropy ($H = b/b^*$, with entropy at static temperature b^*) (see Figure R.42).

Figure R.42 Rayleigh line.

Rayleigh number ($Ra = L^3 \rho^2 g \alpha_{\text{exp}} \Delta T c_p / \eta \kappa = GrPr$)

[fluid dynamics, thermodynamics] Dimensionless number applying to convective and general HEAT TRANSFER, where L is the characteristic length (e.g., thickness of layer), ρ the density, g GRAVITATIONAL ACCELERATION, α_{exp} THERMAL EXPANSION coefficient, ΔT the temperature gradient across the phenomenon, c_p heat capacity, η the VISCOSITY, κ THERMAL CONDUCTIVITY, and Gr the GRASHOF NUMBER and Pr the PRANDTL NUMBER. The Rayleigh number can be used in BOUNDARY LAYER effects during surface heating and provide the thermal gradient.

Rayleigh scattering

[biomedical, general, nuclear] ELASTIC SCATTERING (compare to RAMAN SCATTERING) of LIGHT of a certain wavelength (λ) under interaction with objects smaller than the wavelength as described by English mathematician John William Strutt, also known as LORD RAYLEIGH (1842–1919) in 1871. The scattering CROSS SECTION ($\sigma_R(\lambda)$) is defined as $\sigma_R(\lambda) = (128\pi^5 \alpha_R^2 / 3\lambda^4) (6 + 3\delta/6 - 7\delta)$, with α describing the function to the index of refraction(n) as $\alpha_R = (n - 1)/2\pi N_0$, where N_0 is the PARTICLE density ("concentration") and δ the DEPOLARIZATION factor. The scattered light will be polarized (as can be observed by applying a POLARIZATION

filter to a CAMERA lens, or polaroid sunglasses) With respect to the angular distribution (θ) of scattered radiance L , at a DISTANCE ℓ from the scatterer this rewrites as $L = L_0 \left(\pi^4 \alpha_R^2 / 3 \lambda^4 \ell^2 \right) (1 + \cos^2 \theta)$. Rayleigh scattering provides an explanation to the sky looking blue, since beyond the ATMOSPHERE there is darkness. At great angular distance from the SUN the blue light is remaining from the solar spectrum, whereas closer to the incident ray of the Sun the entire spectrum scatters and provides a COLOR tending to white near the Sun. White clouds, on the other hand, are the result of MIE SCATTERING (see [Figure R.43](#)).

Figure R.43 Blue sky over Mont Michel in France due to Rayleigh scattering of white light emitted by the Sun.

Rayleigh screening

[biomedical, imaging, optics] Screening method for determination of molecular separation while applying the ULTRACENTRIFUGE principle. In this method TRANSILLUMINATION of the sample vial with SOLUTE sediment generates an INTERFERENCE FRINGE pattern. The separation of the fringes has a direct correlation with the concentration of molecular aggregate, which will correlate to the DISTANCE to the axis of rotation.

Rayleigh–Bénard flow

[fluid dynamics] Convection flow. Discrete convective turbulent flow cells occur in a horizontal layer of a FLUID heated from below. Named based on the contributions by the French physicist Henri Bénard (1874–1939) and LORD RAYLEIGH (1842–1919), defined in 1900.

Rayleigh–Gans theory

[computational, optics] SCATTERING approximation for a scattering medium that has an index of refraction close to unity ($n \approx 1$), which shifts the weight to zero scattering ANGLE. The Rayleigh–Gans scattering is described for the condition $\alpha_R = (n - 1)/2\pi N_0 \cong n^2 - 1/4\pi N_0$, see RAYLEIGH SCATTERING. Also known as RAYLEIGH–GANS SCATTERING.

Rayleigh–Gans–Debye scattering

[computational, optics] Transition SCATTERING regime for Rayleigh and Mie scattering under index of refraction of scattering compound close to one (1). Scattering theory based on the contributions from LORD RAYLEIGH (1842–1919), Richard Martin Gans (1880–1954), and PETER DEBYE (1884–1966) (see **RAYLEIGH–GANS THEORY**).

Rayleigh–Jeans equation

[atomic, nuclear, optics] RADIATION law describing the BLACK-BODY radiant power emitted per unit solid angle within a frequency range ($\Delta\nu$), in the limit $h\nu/kT \ll 1$: $P_{\text{BlackBody/unitSolidAngle}} = \left(2k_bT/\lambda^2\right)\Delta\nu$ where $\lambda = c/\nu$ is WAVELENGTH, ν the frequency, c the speed of LIGHT, k_b is the BOLTZMANN CONSTANT, T the TEMPERATURE (in Kelvin). This law was the result of the combined efforts of LORD RAYLEIGH (1842–1919) published in 1900 and Sir James Hopwood Jeans (1877–1946) published in 1905. The validity of the Rayleigh–Jeans is identified by the Rayleigh–Jeans limit which is defined as $\lambda \gg (hc/k_bT)$ beyond this point PLANCK'S LAW is approximately equal to the Rayleigh–Jeans law (also see **BLACK-BODY EMISSION**, **RAYLEIGH EMISSION LAW**, and **ULTRAVIOLET CATASTROPHE**).

Rayleigh–Sommerfeld diffraction

[acoustics] Diffraction theory approached in plane WAVE, in contrast to the SPHERICAL WAVE Huygens–Fresnel diffraction (near-field), modified by GUSTAV ROBERT KIRCHHOFF (1824–1887) as the Fresnel–Kirchhoff diffraction theory. Modifications by the German (Prussia) physicist and mathematician ARNOLD JOHANNES WILHELM SOMMERFELD (1868–1951) of the work by LORD RAYLEIGH (1842–1919) expressed with respect to the Fresnel–Kirchhoff approximation: $A(\vec{q}) = \int_S \kappa(\vec{r}, \vec{q}) [A(\vec{r})/|\vec{q} - \vec{r}|] e^{-ik|\vec{q} - \vec{r}|} dS$, where dS is a surface ELEMENT, $\vec{q}$ a location on the screen, $\vec{r}$ a location of the surface ELEMENT, $A(\vec{r})$ the real value of the complex field AMPLITUDE in location $\vec{r}$, respectively $\vec{q}$; with the coefficient: $\kappa_{\text{RS}} = \cos\alpha/i\lambda$, where λ the wavelength under angular DISPERSION α for the angular position of the surface element; compared to Kirchhoff's interpretation: $\kappa_{\text{RS}} = (1 - \cos\alpha)/2i\lambda$.

Rayleigh–Taylor instability

[astrophysics/astronomy, computational, energy, fluid dynamics, thermodynamics] As part of thermonuclear instabilities with a solar flame the flare propagation becomes unstable when the density of the fuel (ρ_{fuel}) becomes greater than the density of the ash (ρ_{ash}) as described in $\tau_{\text{decay}}^2 = k_g \Delta\rho / 2\rho_{\text{avg}}$, where τ_{decay} represents the DECAY rate of the combustion, g is the GRAVITATIONAL ACCELERATION on the STAR, $\Delta\rho = \rho_{\text{ash}} - \rho_{\text{fuel}}$ the gradient in density between fuel and ash, and ρ_{avg} the average density of the mixture.

R–C Circuits

[electronics, general] Electronic circuit composed of resistors (R) and capacitors (C).

Reabsorption

[biomedical, chemical] The process of lysis (enzymatic or osmotic process in reference to a cellular condition) and assimilation of a substance which is produced by a biological entity as the end result of the cellular breakdown which has been secreted. In biology this describes a process in the KIDNEY.

Reactance (χ_L)

[electronics, general] Electronic parameter pertaining to inductance: L (e.g., coil): $\chi_L = \omega L$, where $\omega = 2\pi\nu$ the ANGULAR VELOCITY and ν the frequency of the alternating current through the “coil,” that is, INDUCTOR.

Reactor

[nuclear] *See* NUCLEAR REACTOR.

Réaumur, René-Antoine Ferchault de (1683–1757)

[general, thermodynamics] Scientist from France who introduced the Réaumur temperature scale with respect to his research in METEOROLOGY. The Réaumur scale used the FREEZING point of water as the zero degree mark, but in contrast to his later scientific follower ANDERS CELSIUS (1701–1744) with the CELSIUS SCALE, set the second calibration point on the scale for the boiling point of water at 80° , also making his scale in segments of 8, “octogesimal.” The Réaumur temperature gauge had significant initial popularity, but was soon replaced by the Fahrenheit scale (by DANIEL GABRIEL FAHRENHEIT, 1686–1736) in the United Kingdom and the United States and the Celsius scale in the rest of the world and is now only of historic value (see [Figure R.44](#)).

Figure R.44 René Antoine Ferchault de Réaumur (1683–1757). (Courtesy of Galerie des naturalistes de J. Pizzetta, Ed. Hennuyer, 1893.)

Reciprocal space

[computational, condensed matter, imaging] Graphic representation using imaginary coordinates that are configured to represent vector orientation that coincide with the normal to the vector in the real space. Real space identifies the locations of atoms in a structural setting, whereas the reciprocal space represents the MAGNITUDE and direction of momentum of the wavevector for the LATTICE structure. In this setting the special DISTANCE between the imaginary coordinates represents the reciprocal of the real interplanar distance. The reciprocal lattice configuration that provides the outline to display the FOURIER TRANSFORM for the wavefunction within the original lattice structure (prevalent lattice configuration: Bravais). The general mode of operations defines the reciprocal lattice vector as the reciprocal of the real interplanar distance multiplied by 2π , placing it in Fourier space, with units radians per unit length; which yield the units of the WAVE vector ($k = 2\pi/\lambda$) used for spectroscopic analysis (cm^{-1}). The reciprocal lattice defines the slopes

and planes of the crystal planes in a lattice structure. The reciprocal lattice can be made “visible” through illumination of a real lattice by X-RAY imaging. Also referred to as Fourier space or k -SPACE (see Figure R.45).

Figure R.45 Diagram representing the transition between real space and reciprocal space. Objects imaged in real space (left) are transformed to reciprocal space using Fourier transformation (FT). In reciprocal space (right-side) the representation may or may not have intersections with the Ewald sphere. The Ewald sphere defines the monochromatic radiation, illustrated as a two-dimensional project in the right-hand side (circle). The narrow-band (monochromatic) radiation is diffracted by the object in the direction that corresponds to the respective intersection of the Ewald sphere with the representation of the object in reciprocal space. For a planar interface there will be specular reflection. Specular reflection is represented by the intersection at the origin, which in turn corresponds to transmission. When assuming a line grating there will be additional intersections, each respectively corresponding to first-order and second-order diffraction within the object. The middle right diagram represents both orders in reflection, as well as in transmission. When imaging a set of planes, similar to what is, for instance, found in a crystal that is diffracting X-rays, the reciprocal space intersection may in actuality be absent. The definition of the orientation of the Ewald sphere is provided by the Bragg equation, which yields the intersect representing the reflections.

Reciprocity rule

R

[chemical] See **BUNSEN–ROScoe RULE**.

Recoil energy

[nuclear, quantum] Interaction of an energetic PARTICLE (elementary, alpha, etc.) with a NUCLEUS, transferring some or all of its momentum without changing the DEGREES OF FREEDOM of the nontranslational states. A specific recoil effect is induced during the emission of ALPHA DECAY. In contrast to resonant absorption of gamma RADIATION by the nucleus of atoms without loss to recoil described by Rudolf Mössbauer (1929–2011) in 1958, used in spectroscopic analysis pertaining to the nuclear ENERGY configuration. Rudolf Mössbauer along with Robert Hofstadter (1915–1990) received the Nobel Prize in Physics for their electron SCATTERING (and related alpha decay) in the nucleus with the recoil energy defining the nuclear energy configuration in 1961 (*also see* **MÖSSBAUER EFFECT**).

Rectifier

[electronics, general] Device used for conversion of ALTERNATING CURRENT (AC) ENERGY and rotating or three-phase current energy into direct current (DC) energy. This can be done in single-phase or multiphase modes. The mechanism of action can be either single-phase rectification or multiple-phase rectification.

The duty cycle of single-phase rectification is only 50%, whereas multiple phases can approach 100% duty cycle, depending on the number of phases involved and the level and participation of multiphase suppression.

Red

[electromagnetism] COLOR in the longer wavelength range for the visible ELECTROMAGNETIC SPECTRUM, considered to be one of the PRIMARY COLORS, in comparison to blue and green. The red color spectrum is at the extreme end of the visible spectrum, ranging from approximately 600 to 650 nm. On the shorter wavelengths LIGHT is yellow and on the longer wavelength side light is invisible INFRARED.

Red dwarf

[astrophysics/astronomy] Galactic STAR, classification that includes the definition for the approximate size of our SUN but much cooler, less than 4000 K (compared to 5800 K for our Sun). The mass of a red dwarf is less than 40% of the mass of our Sun, down to as little as 7.5% of the mass of our Sun. The emission of the red dwarf places it in the late K-spectral type or M-spectral type. The spectral type system for stars was devised by the Danish astronomer Ejnar Hertzsprung (1911–1967) in 1908, which was complemented by the astronomer from the United States HENRY NORRIS RUSSELL (1877–1957), which led to naming the classification the Hertzsprung–Russell diagrams. Red dwarfs presumably have no active nuclear reactions at the surface, the heat primarily emanates by convection. Due to the minimalistic nuclear reaction, remixing hydrogen and helium, these stars can live extremely long, hundreds of billions of years. In comparison, our Sun has an anticipated lifetime of 11 billion years before it reaches the WHITE DWARF stage, of which approximately 4.5 billion years has passed (no prospects for direct changes to the sun's luminosity and temperature at this point) (see [Figure R.46](#)).

Figure R.46 Red dwarf representation; Stellar evolution of the Sun from yellow dwarf expand into huge red giant (left to right).

Red giant

[astronomy/astrophysics] Galactic star that passes through an evolutionary stage toward its demise (process of millions of years). The red giant evolves from a STAR that is low in mass, less than eight times the mass of our SUN. Due to hydrogen burn-up in the center the diameter of the star will grow to a diameter that is in the order of 100 times the size of our Sun, with associated lower ENERGY content, thus cooler and hence emitting at longer wavelength peak emission, creating the red glow. As it continues its growth process it becomes a red super giant with diameter in the order of 500 times that of our Sun, extending past the location of the earth's orbit. Our Sun is anticipated to eventually grow to a red giant with an anticipated increase in luminosity of 10,000 times the current radiance, while it cools to a temperature of 4,000 K with an approximate core temperature of 10^8 K. In the evolutionary process the red giant may progress to

become a WHITE DWARF once the hydrogen has been consumed with its final stage once the helium has been consumed, forming a black dwarf (see [Figure R.47](#)).

Figure R.47 Red giant representation in the vicinity of a planet.

Redox potential

[biomedical, chemical, energy] QUANTIFICATION of the potential to acquire electrons, forming a reduction process (see REDOX REACTION). The tendency that a chemical species will acquire electrons is measured in volts, the redox potential (see NERNST POTENTIAL).

Redox reaction

[biomedical, chemical, energy] Classification of a grouping of chemical reactions that have the OXIDATION reduction as the basis, transferring electrons between chemical species. The chemical interaction basis is either the reduction of electronic charge, either from negative ION to neutral or from neutral to a positive ion known as oxidation; respectively the gain of electrons is known as reduction generating a negatively charged ion (see [Figure R.48](#)).

Figure R.48 Illustration comparing redox reaction with oxidation.

Redshift

[astrophysics/astronomy, computational] DOPPLER shift in spectral emission lines in the direction of longer wavelength due to the fact that the emission source is moving away from the observer, primarily observed on astronomic scale due to movement of stars. The spectral redshift was described in 1848 by HIPPOLYTE FIZEAU (1819–1896) for the first time. The emission lines are recognized transition lines for specific ELEMENTS, specifically hydrogen, helium, and certain metals. The redshift supports the “BIG BANG THEORY;” outlining the continual EXPANSION of the UNIVERSE (*also see* DOPPLER EFFECT) (see Figure R.49).

Figure R.49 Redshift diagram on top for a emitting source moving away with respect to the location of the observer. Doppler shift resulting from moving source. (Courtesy of Aleš Tošovský, Czech Republic.)

Reduced mass

[general] Mass measured when an object placed on a scale is submerged in water. This equates to the mass of the object in water from the mass of the object in AIR: $m_r = m - m_w$.

Reflectance

[atomic, general, optics] Image formed by reflection (see Figure R.50).

Figure R.50 (a) Object may be closer than they appear in the convex mirror and (b) reflection of a bald eagle in flight reflected by the undisturbed surface of the water, where the eagle broke the surface tension to capture a fish that was observed from the sky accounting for the refraction with respect to the underwater location of the fish as observed from air. (Courtesy of Ray Hennessy, <http://www.rayhennessy.com>.)

Reflecting telescope

[general] TELESCOPE using curved mirrors for rays forming and associated magnification in addition to lenses (see [Figure R.51](#)).

Figure R.51 Reflection telescope design.

Reflection

[atomic, general, nuclear, optics] Redirection of ENERGY wave stream that conforms to PARTICLE characteristics, resembling a ball bouncing of a WALL. The path of the WAVE propagation will form an ANGLE with an interface, where the path equates to the rectilinear propagation of a PROJECTILE. The angle of incidence of LIGHT measured with respect to the normal to the surface equals the angle of reflection. Electromagnetic RADIATION is redirected at a boundary that has different optical density from the adjacent medium, pertaining to the DIELECTRIC properties: permittivity and permeability. ACOUSTIC WAVES reflect from a boundary with different density, as do mechanical waves (i.e., water waves). Also described as specular or diffuse reflectance. Specular reflectance creates a real or virtual IMAGE that generally has the outline of the object reversed in the plane of reflection and remains crisp and clearly visible, whereas diffuse reflectance mixes the reflected rays in random directions due to the interaction from a surface or interface that is not perfectly smooth; hence the outline of the image does no longer match the object. Reflection also applies to waves of electrons, using the DE BROGLIE WAVELENGTH as the wave phenomenon next to the particle characteristics, both applied to electron microscopy imaging (see [Figure R.52](#)).

Figure R.52 Principle of reflection: equal angles with respect to normal to the surface.

Refraction

[acoustics, general, nuclear, optics] Redirection of wave of ENERGY at an interface with a change in direction that has a diminished vector component in the direction of the incident ray; the ray proceeds in the second medium with a direction that is a function of the density and obeys the equivalent of SNELL'S LAW for all forms of energy. In OPTICS the refraction is coupled to the characteristics of the medium identified as the index of refraction; linking the velocity of propagation to the definition of the medium. Refraction also applies to waves of electrons, using the DE BROGLIE WAVELENGTH as the WAVE phenomenon with respect to electron microscopy imaging (see Figure R.53).

Figure R.53 (a) Principle of refraction. (b) Archerfish “spitting” at insect above the waterline, compensating for the refraction, hitting the insect and capturing it for consumption. Apparently the archerfish is able to modulate the jet-phase flow velocity (dispersion, frequency modulation, etc.) to shape the jet providing higher efficiency in disabling the prey. Note that the jet is a wave phenomenon.

Refraction, index of (n)

[general, optics] See INDEX OF REFRACTION.

Refraction, law of

[general] See SNELL'S LAW.

Refrigeration cycle

[thermodynamics] Compression cycle leading to a reduction in temperature. This principle applies to refrigeration: refrigerator and air-conditioning (*also see* RANKINE CYCLE).

Reines, Frederick (1918–1998)

[astrophysics/astronomy, general, nuclear] Physicist from the United States. Discoverer of the NEUTRINO and antineutrino, in collaboration with the American physicist Clyde Lorrain Cowan (1919–1974) in 1956. The equivalent mass of the antineutrino has been derived to be less than $27 \text{ eV}/c^2$, with c the speed of LIGHT in 1986. Additional efforts of Frederick Reines were in the description and the workings of SUPERNOVA stars.

Reines received the Nobel Prize in Physics with Martin Lewis Perl (1927–) in 1995 for the discovery of the TAU LEPTON (see [Figure R.54](#)).

Figure R.54 Frederick Reines (1918–1998).

Relative density

[general] The nondimensional expression for the density of an object expressed as the ratio of the mass-in-air to the difference of the mass-in-air and the mass-under-water: relative density = $\rho/\rho_w = (m/V)/(m_w/V) = m/m_w = m/(m - m_r)$ = specific gravity, which is equivalent to the specific gravity. The quantity is the density while the subscripts respectively represent the mass of displaced FLUID and REDUCED MASS (or APPARENT MASS). The concept was first introduced by AL-BIRUNI (973–1048) in approximately 1025, while he was a philosopher and scientist in the Persian Empire.

Relative humidity (RH)

[thermodynamics] Measure of the ratio of water VAPOR content, measured as partial pressure (P_i), in a volume of a mixture of gases at a specific temperature with respect to the partial pressure of saturated water vapor in equilibrium with a LIQUID water bath, where saturated water vapor defines 100% percent. $RH = (\text{actual vapor density at a certain temperature} / \text{saturated vapor density at the same temperature}) \times 100\% = (P_{H_2O,T} / P_{SatH_2O,T}) \times 100\%$.

Relative permeability

[fluid dynamics, thermodynamics] In a cyclic thermodynamic process, the FLUID saturation will reveal HYSTERESIS with respect to PHASE transitions between the various phases in the mixture, specifically under conditions of a porous medium. The absolute permeability of a porous medium defines the ability to transmit fluids. The effective permeability relates the permeability of a particular phase in the context to other phases present. The relative permeability is the ratio of the effective permeability to the baseline permeability of the porous medium (e.g., rock). Permeability has its relevance in fracturing (fracking), where there is a presence of water, OIL, and other fluid media (including gases) in porous and semiporous rock or rock that will need to be made more permeable.

Relative permittivity

[thermodynamics] The DIELECTRIC permittivity can generally be considered as independent of the external MAGNETIC and electric fields provided the respective magnitudes are low. The permittivity can be described as dependent on both temperature and density, expressed relative to the permittivity of VACUUM as follows: $\epsilon = \epsilon_0 + (\rho/M)[\alpha + (d^2/3kT)]$, where k is the Boltzmann constant, d the ELECTRIC DIPOLE MOMENT of the respective molecules in the volume, ρ the density, M the MOLECULAR WEIGHT, and α the molecular POLARIZATION.

Relaxation time

[biomedical, computational, mechanics, nuclear, solid-state] Time period in which a phenomenon decreases to a value that is a fraction e^{-1} times the initial value. This may relate to, for instance, temperature effects, SPIN (ELECTRON SPIN under excited conditions), MAGNETIC RESONANCE (ref. MRI), electronic circuit current fluctuations (CAPACITOR discharge), mechanical (stress/strain) as well as NUCLEON and electron transitions, however, not limited to these alone.

Renaldini, Carlo {Rinaldini} (1615–1698)

[general] Engineer and nobleman from Italy who was one of the first scientists to suggest the use of the PHASE transitions of water as calibration points for a temperature scale (i.e., THERMOMETER) and provided experimental proof of the concepts in 1654. Note that the originators of several temperature scales, such as ANDERS CELSIUS (1701–1744), DANIEL GABRIEL FAHRENHEIT (1686–1736), RENÉ ANTOINE FERCHAULT DE RÉAUMUR (1683–1757), and WILLIAM THOMSON, 1ST BARON KELVIN (1824–1907) all lived after Renaldini (see [Figure R.55](#)).

Figure R.55 Carlo Renaldini (1615–1698).

Rényi, Alfréd (1921–1970)

[imaging, theoretical, thermodynamics] Mathematician and physicist from Hungary. Alfréd Rényi is known for his contributions to PROBABILITY theory, graph theory, and combinatorics as well as number theory. His contributions to the stochastic nature of thermodynamic process is expressed by the RÉNYI ENTROPY (see Figure R.56).

Figure R.56 Alfréd Rényi (1921–1970). (Courtesy of Hungarian Foreign Ministry, Hungary.)

Rényi entropy

[computational, imaging, theoretical, thermodynamics] Theoretical analysis of the additive effects of independent events. Practically, it is the derivative of the (Gibbs) free energy (G) with respect to the functional parameter for the system, introduced by ALFRÉD RÉNYI (1921–1970). The entropy is defined by this parameter; assume the spatial factor “ q ,” describing the state of an “event,” with respect to the TEMPERATURE (T) of the system, described as $(dG/d(1/q))_T$. Rényi’s approach uses the stochastic influences and improves on the Shannon entropy model, which is a linear approximation on averaging. The entropy approach incorporates an exponential function to describe the PROBABILITY (p) aspect of achieving certain states (j) expressed as the “information” (information potential ($I(p)$)) in under certain conditions for a multidimensional system consisting of a range of independent events: $I(p) = \mathcal{G}^{-1} \{ \sum_{j=1}^N p_j \mathcal{G}(I_j(p)) \}$, where $\mathcal{G}$ provides the format of interaction for independent events, which is $\mathcal{G} = e^{*q}$ for Shannon’s model, and in the model by Rényi this is replaced by $\mathcal{G} = e^{*-2(1-\alpha)q}$, with $I_j(p)$ the information potential estimator for the respective states (j), e^* a coefficient for the system, q the localization factor, α a scaling parameter, and I -norm designated as the NORMALIZATION of the maximum likelihood distribution. The Rényi entropy reduces to $I_\alpha(p) = [1/(1-\alpha)] \log(\sum_{j=1}^N p_j^\alpha)$, defining a family (plural) of information measures (Rényi entropies).

Reproduction factor

[atomic, nuclear] See MULTIPLICATION FACTOR.

Reserve volume (RV)

[biomedical, fluid dynamics] Classification of lung volumes, consisting of INSPIRATORY RESERVE VOLUME and expiratory reserve volume. The vital capacity of the lung is the sum of the inspiratory reserve volume, the expiratory reserve volume, and the TIDAL VOLUME; where the combination inspiratory reserve volume and

tidal volume constitutes the **INSPIRATORY CAPACITY**. The expired reserve volume refers to the lung volume that can be forcefully exhaled what is remaining after normal expiration (see [Figure R.57](#)).

Figure R.57 Diagram of respiration and the two kinds of reserve volume involved.

Residual nucleus

[atomic, nuclear] The residue of a nuclear disintegration from the base atomic structure, where a different kind of **PARTICLE** is emitted resulting from an incident particle interaction, or more than one particle is emitted. The process is referred to as the reaction of transmutation, indicating that the **NUCLEUS** is transmuted into another nuclear species.

Residual volume

[biomedical, fluid dynamics] The lingering quantity of **GAS** remaining in the lungs after exhalation to the maximum effort. Residual volume and other **TIDAL BREATHING** parameters can be measured with a spirometer. The volume of **AIR** occupied in the lung remaining after normal expiration is called the functional residual capacity, which constitutes the expired reserve volume and the residual volume (see **RESPIRATION** and **PHYSIOLOGIC DEAD SPACE**).

Residuals

[computational, fluid dynamics] Method of solving for the Navier–Stokes equation using “weighted residuals.” The weighted residuals are the statistical distributions with regard to the error in the order of termination for the polynomial development of the **SOLUTION** function.

Resistance

[biomedical, electronics, fluid dynamics, mechanics] Reactance to a phenomenon, diminishing the **MAGNITUDE** of a physical parameter that defines the system. In **ELECTRONICS** either the current or the voltage is reduced due to resistance, while flow in general is reduced as a result of resistance, specifically pertaining to

fluid-dynamic conditions. Under mechanical translation, the resistance is embodied by frictional forces or general hindrances such as unevenness in the surface or a wedge between two surfaces. Under biomedical conditions the resistance is also offered through the presence of an **ANTAGONIST** muscle with respect to the intended **MOTION**. In electronics the electrical resistance follows from **OHM's LAW**, relating the voltage drop (V) over a resistance (R) due to a **CURRENT** (I) as $V = IR$.

Resistor

[electronics, general] Physical device in electronic circuit that obeys **OHM's LAW** and provides a voltage drop between the two poles when a current is applied (*see* **RESISTANCE**) (*see* [Figure R.58](#)).

Figure R.58 Electrical resistor in electronic circuit and color code used to identify the ohmic values for conventional resistors.

Resolution

[general] Due to the **DISTANCE** factor between the object under observation and the viewing device resolution is expressed by the angular limit of the separation resolution between two points on an object. The resolution is provided by the **Raleigh criterion**, or alternatively the **ABBE CONDITION** (*also see* **AIRY DISK**).

Resolving power

[general, nuclear] The ability to distinguish between two events or two locations on an object, respectively identify the minimum separation between two objects. Newspaper print in particular takes advantage of

this phenomenon, relying on an observation DISTANCE that will blend the half-tone dots in the printed images into a grayscale, or COLOR, smooth visual interpretation (see [Figure R.59](#)).

Figure R.59 Resolving power.

Resonance

[acoustics, atomic, computational, electromagnetism, fluid dynamics, general, mechanics, quantum]

Three types of resonant systems can be identified: (1) mechanical (e.g., ACOUSTICS), (2) electromagnetic, and (3) electronic. A mechanical system under temporal fluctuating external force will come to resonance when the driving frequency matches the mechanical boundary conditions of the system, either dimensions in multiples of half (e.g., closed box, solid stick, closet with door closed, etc.) or quarter wavelengths (e.g., open box, flute). Alternatively, an electronic system will come to resonance when the applied external alternating electrical potential matches the circuit conditions for the characteristic frequency of the system, for instance, the free-running frequency: $\nu = 1/2\pi\sqrt{LC}$ for an undamped CAPACITOR (C) and INDUCTOR (L) circuit, respectively, adding DAMPING by including a RESISTANCE in the circuit. In electronic circuits, there are three resonant configurations: series, parallel, and two branch. A resonant electromagnetic system refers to a PHOTON, which by definition has an infinite lifetime (*also see* OSCILLATION, MASS-SPRING SYSTEM, FREQUENCY, RESONANT, and Q-FACTOR [quality factor]) (see [Figure R.60](#)).

Figure R.60 Resonance.

Resonance absorption

[atomic] Electromagnetic absorption that matches the wavefunction of an atomic orbit, hence in **RESONANCE** with the electron **ENERGY** for excitation to the next energy level. A particular example of resonance absorption are the Lyman lines of hydrogen in the far **ULTRAVIOLET**.

Resonance frequency

[acoustics, biomedical, imaging] Frequency of oscillatory **ENERGY** field that matches the autonomic frequency of one of the parameters that define a system. In **ACOUSTICS** the frequency of a structure is directly dependent on the dimensions of the device, where at least one of the dimensions will need to match a quarter or a half wavelength multiplied by an integer, depending on whether the ends are loose (free to move independently) or fixed, respectively. In magnetic resonance imaging (MRI and NMR, respectively) the **RADIO** frequency perturbation of the **MAGNETIC FIELD** will need to match a oscillatory frequency of the **NUCLEAR MAGNETIC MOMENT** spin, usually in the radio frequency range. A structure exited at the resonance frequency and continuously stimulated will acquire a significant amount of energy which may eventually result in failure of the structure. Microwave ovens (i.e., magnetron) apply **MICRO-WAVE** electromagnetic **RADIATION** to bring water to its resonant **VIBRATION** relying on **DIPOLE** interaction, hence raising the local temperature and thus heating the food (i.e., water) (*also see* **FREQUENCY, RESONANT**) (see [Figure R.61](#)).

Figure R.61 Bell ringing at its resonance frequencies. Due to the shape of the bell there are a multitude of vibrational characteristic dimensions, which provide the spectrum of the sound of the bell, the "color" of the sound. Vibrating string with frequency determined by the tension and the length of the string as defined by "father" Marin Mersenne (1588–1648), see "**MERSENNE**."

Resonance potential

[atomic] The **ENERGY** required to raise an electron from its **GROUND STATE** to an excited state with certain associated freedom of movement, hence dissociating the **ATOM**. On an atomic level this requires traversing a potential energy **BARRIER**, the resonance potential. This concept was validated by **JAMES FRANCK** (1882–1964) and **HEINRICH HERTZ** (1857–1894) in 1913, who verified the dissociation energy of mercury vapor under 4.9 eV applied energy, the resonance potential for mercury, a single atom **GAS**. Mercury has an **IONIZATION POTENTIAL** of 10.4 eV, however at the resonance potential the electrons are in direct interaction with the **CATHODE** ray electrons in the **VACUUM** tube. The **RESONANCE** of the excited

electrons and the ballistic electrons results in a direct decrease in the current in the vacuum tube (*also see IONIZATION*) (see [Figure R.62](#)).

Figure R.62 Resonance potential, graphical representation of the Feshbach resonances in the $F + H_2 \rightarrow HF + H$ chemical reaction. (Courtesy of Dalian Institute of Chemical Physics, Chinese Academy of Sciences; Group 1102: Laboratory of Reaction Dynamics; Dalian, Liaoning, China.)

Resonance reactions

[nuclear] In the process of nuclear interaction resulting from PROJECTILE particles there are opportunities for population of EXCITED STATES by PARTICLE capture (e.g., NEUTRON or charged particle), where RESONANCE is induced supporting a constant reaction rate resulting from capture at the appropriate ENERGY (see [Figure R.63](#)).

Figure R.63 Resonance reaction: chemical reaction with recursive energy exchanges.

Resonance states

[atomic, condensed matter] Peak in the ENERGY density for subatomic particle interaction with nuclides (e.g., BARYON, upsilons mesons) resulting in an excited state that is a function of the CROSS SECTION of the PARTICLE interaction providing the RESONANCE peak: $\Gamma_r = \hbar/\tau$, where $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK'S CONSTANT and τ is the lifetime of the excited state of the particle or the lifetime of the particle itself. The resonance state is an indication of the energetic width of the excited state, indicating the PROBABILITY of interaction.

Respiration

[biomedical] The process of oxygen intake by means of exchanging AIR by exhaling low SATURATION PRESSURE oxygenated fluids and inhaling high saturation pressure fluids. In the same process the carbon dioxide exchange is from high to low due to CARBOHYDRATE oxidation in the biological medium producing carbon dioxide as a metabolic waste product. The air intake/outflow is generally comprised of the following constituents and relative values with variable water VAPOR PRESSURE depending on RELATIVE HUMIDITY. Intake 20% O₂ – 7% N₂ – 60% CO₂; outflow 16% O₂ – 7% N₂ – 64% CO₂. Respiration efficiency is directly correlated to the exchange in volumes and the total volume of the respiration device (i.e., lung) (see RESIDUAL VOLUME, TOTAL LUNG VOLUME, EXPIRED VOLUME, INHALED VOLUME, and VITAL CAPACITY). The oxygen—carbon dioxide exchange takes place in the Alveoli of the lung under a blood–gas BARRIER (see ALVEOLI, HEMOGLOBIN, and LUNG) (see Figure R.64).

Figure R.64 Human respiration.

Rest energy (E_0)

[general, relativistic] The ENERGY of a system with mass m in a particular state, consisting of momentum and velocity under relativistic conditions has a rest energy $E_0 = mc^2$, where $c = \sqrt{\mu_0 \epsilon_0}^{-1} = (\mu_0 \epsilon_0)^{-1/2} = 2.99792458 \times 10^8 \text{ m/s}$ is the speed of LIGHT in VACUUM.

Rest mass

[atomic, nuclear] Relativistic mass for a system containing a mass m_0 that consists of movement with velocity v with respect to an observer in a reference frame, defined as $m_r = m_0 / \sqrt{1 - (v^2/c^2)}$, where $c = \sqrt{\mu_0 \epsilon_0}^{-1} = (\mu_0 \epsilon_0)^{-1/2} = 2.99792458 \times 10^8$ m/s is the speed of LIGHT in VACUUM.

Resting potential

[biophysics, chemical, electromagnetism, energy] See MEMBRANE POTENTIAL.

Retina

[biomedical, chemical, optics] Cellular layer on the inside WALL of the EYE on the opposite side with respect to the LENS. The retina has two types of CELL for the detection of light: RODS and CONES. The retina of the HUMAN EYE contains approximately 120 to 130 million rods and 6.5 to 7 million cones (the cones are concentrated primarily in the FOVEA of the eye). The rod cells are primarily geared to the detection of radiance, and provide black and white (grayscale) vision. The cones are diversified in three specific sensitive wavelength ranges, respectively RED, green, and blue with a broad sensitive range, largely overlapping. The cones of the eye are sensitive approximately from 330 to 660 nm, which varies with AGE and depending on the applied radiance from the source. The retina has a pigment layer that can reduce the MAGNITUDE of light that will be collected at the rods or cones. The LIGHT incident on the lens of the eye will traverse the VITREOUS HUMOR before reaching the retina. At the retina the pigment layer is encountered first; next the light traverses the choroid respectively (vascular layer), before the light is reflected from the sclera (the white part of the eye), after which the light returns back through the pigmented layer before detection is possible in the rods and cones. The macula provides high-resolution COLOR and black and white vision in a spot of approximately 5.5 mm diameter (depending on the size of the eye), with the central fovea (diameter of approximately 1.5 mm) which contains only cones. The rods are spread out over a large surface and yield dark vision as well as peripheral vision. (also see EYE) (see Figure R.65).

Figure R.65 Retina. Including a representation of the area of the retina where the optic nerve leads off to the rain, with nerve fibers instead of rods and cones leaving a proverbial and true "blind spot." Illustration of the three color vision cone sensitivity yielding ultimate white color by signal analysis integration.

Reverberation

[acoustics, fluid dynamics, general] The compounded cumulative effect of multiple reflections of **SOUND** waves within an enclosure. The characteristics of reverberation created in an enclosed environment are affected by the materials of which the enclosure is constructed as well as the material construction (geometry and materials) of any object and partitions in the enclosure and the size and shape of the enclosure. Materials can both selectively dampen a spectral profile and reflect (see [Figure R.66](#)).

Figure R.66 Reverberation: cymbal, triangle, and drum skin vibrating under percussion by hand.

Reverse osmosis

[biomedical, chemical, general] Water purification process that uses a **SEMIPERMEABLE MEMBRANE** to filter out potentially harmful, and generally unwanted constituents and ingredients from unknown source or unreliable quality water supply. Osmosis itself is the process of influencing the flow of a **SOLUTE**, primarily water, to pass across a (semipermeable) membrane between two different concentration solutions, with an inherent partial pressure gradient, forcing the **SOLVENT** flow to further dilute the higher solute concentration on one side of the membrane. One specific application is the removal of **SALT** from seawater (desalinization) for drinking purposes. Reverse osmosis applies external pressure, thus modifying the chemical potential, which will force the solvent flow to counterbalance the **OSMOTIC PRESSURE** resulting from the solutes. The mechanism of action thus retains the solute on the pressurized side of the membrane and the solvent will pass through (see [Figure R.67](#)).

Figure R.67 Reverse osmosis process, as well as used in desalinization.

Reverse-biased diode

[electronics, general] Semiconductor **DIODE** that is placed in a circuit in conductive direction that is opposite the favored conduction. The general definition of the diode is an electrical device that allows current to move through it in one direction preferred over the opposite direction (*see* **DIODE** and **pn-JUNCTION**; *also see* **ZENER DIODE**).

Reynolds, Osborne (1842–1912)

[biomedical, fluid dynamics, thermodynamics] Scientist from Ireland. Osborne Reynolds is known for his contributions to scaling of flow and the definition of boundary conditions in a flow system. Specific contributions were in the understanding and conditions affecting the onset and persistence of turbulent flow. Additional work by Reynolds was in the **HEAT TRANSFER** between solids and fluids. The work of Osborne Reynolds has provided the Reynolds numbers for flow and for heat transfer and helped in the design of objects to influence the aerodynamic aspects, such as the dimples on the **GOLF BALL**. The dimples in the surface of the golf ball enhances **TURBULENCE**. This turbulence narrows the **WAKE** (concurrently reduces the flow **RESISTANCE**) and will result in an increase of the trajectory **DISTANCE** of the ball by up to 50%. The dimples in the golf ball result in a specific **REYNOLDS NUMBER** for flow, which provides the theoretical conditions for minimal velocity to induce turbulence. On an anecdotal note, Reynolds described the phenomenon of wet sand drying out when one steps in the sand locally. Reynolds recognized that lapping waves bring sand to an optimal packing. The granular packing yields sand grains as close together as they can get. Under the influence of external compaction resulting from the footprint more empty space is created, allowing the water to flow into the sand mass, temporally draining the water from the surface (*see* [Figure R.68](#)).

Figure R.68 Osborne Reynolds (1842–1912) in 1903, painted by John Collier.

Reynolds experiment

[fluid dynamics] Experimental design to illustrate **LAMINAR FLOW**, turbulent flow, and the progression (transitional flow) from laminar to fully turbulent flow.

Reynolds number

[biomedical, fluid dynamics] $Re = (D \times \rho \times v) / (\eta \times g)$, dimensionless number portraying the ratio of the net inertial force to the viscous force, where η is the VISCOSITY, D the core length of the phenomenon (i.e., length of the tube of object, e.g., automobile, train, plain, etc.), ρ the DENSITY (also SPECIFIC WEIGHT) of the FLUID, v the average relative flow velocity, and g is the GRAVITATION due to acceleration.

Reynolds number, magnetic ($Re_m = \mu \sigma v_{fl} L$)

[fluid dynamics, geophysics] Dimensionless number applying to magnetic field–fluid DYNAMICS describing the interaction of MAGNETIC FIELD and FLUID flow (e.g., magma), where μ is the DIELECTRIC permeability, σ the electrical conductivity, L the characteristic length, and v_{fl} the FLUID FLOW VELOCITY. The MAGNETIC REYNOLDS NUMBER can indicate when MAGNETIC convection over the RELAXATION TIME is small with respect to the size of the phenomenon. For large magnetic Reynolds number ($Re_m \gg 1$), the electromagnetic (i.e., the electric current and magnetic field) response can be 180° , or π rad out of PHASE with the flow, resulting in abrupt changes in the local MAGNETIC FIELD with associated ENERGY surges and shock waves.

Reynolds stress

[fluid dynamics] Terms in the Navier–Stokes equation related to FLUID shearing stresses, as expressed by the term $-u_i u_j$ for the velocity components with respect to all the DEGREES OF FREEDOM in $U_j (\partial u_i / \partial x_j) = (\partial P / \partial x_i) - (\partial / \partial x_j) (u_i u_j) + \eta_{kin} \nabla^2 U_i$, where u_i is the perturbation and u_i the mean MAGNITUDE of the i component of the velocity profile in direction x_i , $\nabla^2 = \sum (d^2 / dx_i^2)$ the Laplace operator, η_{kin} the KINEMATIC VISCOSITY, and P the mean pressure.

Rheobase

[biomedical, chemical, electronics] See RHEOBASIC CURRENT.

Rheobasic current

[biomedical, chemical, electronics] The smallest ION exchange measured as current across the biological CELL MEMBRANE that has the capability to induce DEPOLARIZATION and hence activate the cell to perform its function. It is also known as RHEOBASE.

Rheological diagram

[fluid dynamics] Diagram outlining the flow classification of Newtonian versus non-Newtonian, as well as defining PLASTICITY; plotting the shear stress against the rate of deformation for a FLUID (see [Figure R.69](#)).

Figure R.69 Rheological diagram: illustrating the plastic flow (e.g., Bingham medium) under fluid-dynamic conditions response, rather than deforming elastically in response to an applied shear stress.

Rheology

[biomedical, computational, fluid dynamics, geophysics, mechanics, thermodynamics] Flow of inelastic condensed MATTER, also described as Bingham PLASTICS. The viscosity of the FLUID is flow velocity dependent and can be time dependent. Due to the nonlinear and inelastic nature this flow process is usually irreversible, the exception is generally for BLOOD flow, as a colloid SOLUTION flow. Blood flow changes with tube dimension (artery, arteriole, CAPILLARY, venule, VEIN, etc.) aspect ratio to the red blood CELL diameter. The flow of media that are subject to nonlinear behavior of shear stress and strain, also described by the Herschel–Bulkley model. Blood is the most recognized rheological LIQUID, other media include toothpaste, volcanic lava/magma flow, and make-up to name but a few.

Riccati, Jacopo Francesco; Count (1676–1754)

[computational, fluid dynamics] Mathematician from Italy. Count Riccati devised several expressions to perform differential equations with respect to quadratic expressions in an unknown function, the most well-known is the Riccati equation (see Figure R.70).

Figure R.70 Count Jacopo Francesco Riccati (1676–1754).

Riccati equations

[acoustics, computational, fluid dynamics, quantum] Mathematical first-order differential equation designed by COUNT JACOPO FRANCESCO RICCATI (1676–1754). The equation is quadratic in the unknown function that needs to be solved for. The general convoluted expression for the Riccati equation is given as $dy/dx = a^*(x) + b^*(x)y(x) + c^*(x)y^2(x)$, where $a^*(x)$, $b^*(x)$ and $c^*(x)$ are system-defining parameters, with respect to location-specific conditions. The Riccati equation reduces to the Bernoulli equation under certain conditions, and another example applies to the WAVE EQUATION in acoustic propagation in a geometry with curved walls. Other specific applications are found for solving the wave propagation for the SCHRÖDINGER EQUATION, respectively with respect to wave propagation in layered inhomogeneous media.

Richardson, Owen Willans, Sir (1879–1959)

[computational, solid-state] Physicist from Great Britain, known for his work on THERMIONIC EMISSION and the RICHARDSON'S EQUATION. Sir Richardson received the Nobel Prize in Physics for his thermionic emission work in 1928 (see [Figure R.71](#)).

Figure R.71 Sir Owen Willans Richardson (1879–1959) at the 1929 Solvay Conference; Fifth Solvay International Conference on Electrons and Photons under chair Hendrik Lorentz (1853–1928), far right front row.

Richardson–Dushman equation

[thermodynamics] Relationship between the “free electron,” respectively ION thermionic emission with respect to the current density (J_s) through a CONDUCTOR and the work function (ϕ_w) of the emitting material as a function of temperature (T): $J_s = A_{RD} T^2 \exp(-\phi_w/kT)$, where $A_{RD} = 4\pi me k_b^2 / h^3$ the Richardson–Dushman coefficient (an indication of the PROBABILITY for release of charges per unit CROSS SECTION), and $k_b = 1.3806488 \times 10^{-23} \text{ m}^2\text{kg/s}^2\text{K}$ the Boltzmann coefficient, m the electron mass, $e = 1.60217657 \times 10^{-19} \text{ C}$ the electron equivalent charge and $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK'S CONSTANT. Described by SIR OWEN WILLANS RICHARDSON (1879–1959), one particular application is in CATHODE emissions. The THERMIONIC EMISSION as initially described by the British scientist Frederick Guthrie (1833–1886) in 1873, later attributed to the scientist and statesman from the United States THOMAS ALVA EDISON (1847–1931) based on his published work in 1880. It is also known as Richardson equation.

Richardson's equation

[atomic, computational, nuclear] See RICHARDSON–DUSHMAN EQUATION. It is also known as RICHARDSON'S LAW.

Rician noise

[acoustics, biomedical, imaging, quantum] PROBABILITY distribution with respect to random signals generated as a result of nonlinear effects, providing a deviation from standard GAUSSIAN NOISE distribution. The Rician distribution specifically applies under MAGNETIC RESONANCE excitation and detection. Additionally, in ULTRASOUND imaging the random secondary resonance resulting from vibrational excitation is considered Rician noise. Rician noise takes into consideration the frequency distribution as well as the PHASE differences in the collected WAVE patterns with respect to the incident source, including the angular redistribution resulting from scatter. The Rician noise distribution is written as a function of the standard Gaussian distribution as $p_R(I_\ell(\vec{r})) = \left[I_\ell(\vec{r}) / \sigma_{sd} \right] \exp \left[- \left(I_\ell(\vec{r})^2 + A(\vec{r})^2 \right) / 2\sigma_{sd}^2 \right] \times J_0 \left(I_\ell(\vec{r}) A(\vec{r}) / \sigma_{sd}^2 \right)$, where $I_\ell(\vec{r})$ is the location-specific collected (noisy) SIGNAL magnitude, σ_{sd} the standard deviation with respect to the GAUSSIAN DISTRIBUTION, $A(\vec{r})$ the noise-free signal magnitude as a function of location (in approximation: $I_\ell(\vec{r}) = \sqrt{A(\vec{r})^2 + \sigma_{sd}^2}$); where the signal-to-noise ratio is defined as $SNR = A(\vec{r}) / \sigma_{sd}$, and $J_0(I_\ell(\vec{r}) A(\vec{r}) / \sigma_{sd}^2)$ a modified zero-order Bessel function of the first kind (see Figure R.72).

Figure R.72 Rician noise in MRI image outlined in detail focal areas. (Courtesy of Antonio Tristán Vega, submitted at Mathworks.)

Right-hand current rule

[general] Also see **RIGHT-HAND FORCE RULE**, which describes a different aspect. The direction of the **MAGNETIC FIELD** resulting from a current (virtual flow of positively charged particles) is indicated by the direction of the fingers when the hand grabs (encloses) the **POSITIVE CHARGE** flow (i.e., wire with current) and the thumb points in the direction of the current flow (see [Figure R.73](#)).

Figure R.73 Right-hand current rule.

Right-hand force rule

[general] The **FORCE** (F) applied on a current resulting from a moving charge (expressed as the charge q with velocity $\vec{v}$) in a **MAGNETIC FIELD** (B) follows the direction of the “lifted middle finger,” when the charge moves in the direction of the extended thumb and the **MAGNETIC field** point in the direction of the extended index finger, defined by $\vec{F} = q\vec{v} \times \vec{B}$. Also see **RIGHT-HAND CURRENT RULE**, which describes a different aspect (see [Figure R.74](#)).

Figure R.74 Right-hand rule.

Ripple

[fluid dynamics] See **WAVE**.

Ritter, Johann Wilhelm (1776–1810)

[astrophysics/astronomy, general, optics] Discoverer of ULTRAVIOLET RADIATION in 1801 based on the work by the Swedish researcher CARL WILHELM SCHEELE, published in 1777. The work by Scheele describes the discoloration of paper coated with silver chloride when exposed to sunlight. Ritter also described the GALVANIC MECHANISM under the influence of LIGHT and he described the ELECTROLYSIS of water. Observations of current distributions in branched wires predate the publications by GEORG OHM (1789–1854) and GUSTAV KIRCHHOFF (1824–1887) (see [Figure R.75](#)).

Figure R.75 Johann Wilhelm Ritter (1776–1810), as he would have looked in 1804.

Riva-Rocci, Scipione (1863–1937)

[fluid dynamics] Physician from Italy. Inventor of the mercury SPHYGMOMANOMETER in 1896, device used to measure BLOOD PRESSURE (see [Figure R.76](#)).

Figure R.76 Scipione Riva-Rocci (1863–1937). (Courtesy of photographer Hans Christophersen and the Danish National Archive.)

Riva-Rocci cuff

[biomedical, fluid dynamics] Pressure cuff on the device introduced by **SCIPIONE RIVA-ROCCI** (1863–1937) for the **BLOOD PRESSURE** detection in the arm. The cuff is inflated and hence compresses the tissue surrounding the artery in the arm (brachial artery), thus restricting the blood flow. When the pressure is diminished the flow of blood in the artery intermittently, creating a **VIBRATION** of the vascular **WALL** similar to the **RESONANCE** of the an inflated balloon that is squeezed at the opening as **AIR** is escaping. The pressure in the cuff is raised above the known highest pressure recorded for any human heart before gradually reducing the pressure in the cuff over time. As the external pressure drops, instantly the blood will begin intermittent flow under the equilibrium condition where the applied pressure is equal to the **SYSTOLIC PRESSURE** applied by the **HEART**, not accounting from differences in height between the heart and the location of the pressure cuff and any inherent and residual flow **RESISTANCE** between the heart and the location of the pressure cuff, based on Bernoulli's law. Further reduction in pressure will eventually drop below the **DIASTOLIC PRESSURE**, at which point this will cause a cessation of the flow-induced vascular vibrations. In this manner the equivalent systolic and diastolic pressure for the individual is derived with relative accuracy. The device uses the **ACOUSTICS** resulting from the restricted and lack of blood flow using the vascular vibration identified by the Russian scientist **NIKOLAI SERGEYEVICH KOROTKOV** (1874–1920: Николай Сергеевич Коротков), known as the Korotkov sounds (see [Figure R.77](#)).

Figure R.77 Riva-Rocci cuff and Littmann stethoscope.

R

RMS value

[general] Root mean square, averaged value of **MAGNITUDE** of parameter using the weighted average of the square of all data points (n_i), by addition and divided by the number of data points, subsequently the square root is taken to yield the root-mean-square average: $\text{RMS} = \sqrt{\sum_{i=1}^N n_i^2 / N}$.

Roberval, Gilles Personne de (1602–1675)

[computational, general] Mathematician from France. The work of Gilles de Roberval was a prelude to modern mathematics ("infinitesimal calculus"). Additionally, the work of de Roberval supported the Copernican **HELIOCENTRIC** system; the **SUN** as the center of our planetary system, which was not fully accepted. The prior work of **NICOLAUS COPERNICUS** (1473–1543) also provided supporting evidence.

Gilles Personier (Personne) de Roberval was a contemporary of RENÉ DESCARTES (1596–1650), and they supported joint scientific beliefs (see [Figure R.78](#)).

Figure R.78 Gilles Personne de Roberval (1602–1675). Gilles de Roberval was a founding member of the French Academy of Sciences and the portrait was made during the inauguration in 1666; originally painted by Charles le Brun.

Robot

[acoustics, computational, electronics, fluid dynamics, mechanics, optics] Autonomous wired or wirelessly controlled device, respectively (*see* ROBOTICS) (*see* [Figure R.79](#)).

Figure R.79 Example of robots. Robot created by Zoe Crider.

Robotics

[acoustics, computational, electronics, fluid dynamics, mechanics, optics] Technological manifestation of mechanical devices that can operate by either remote control or independently under computer or MICROPROCESSOR (microchip) supported actuation, that is, ROBOT. Robots are devices that result from the integration of multifaceted aspects of a range of diverse technologies and ENGINEERING efforts, including but not limited to

MOTOR control, sensory PERCEPTION, information technology, cause-and-effect response autonomous “learning,” IMAGE acquisition, and data processing. The word “robot” originates from the play R.U.R. (Rossum’s Universal “Robots;” original title: Rossumovi Univerzální Roboti), by the Czechoslovakian writer Karel Čapek (1890–1938) published in 1920. The word robot originates from the Slavic word robota (and similarly also found in neighboring Cyrillic languages), which means “work” or “labor” (see [Figure R.80](#)).

Figure R.80 House robot developed by Honda.

Rock salt

[condensed matter, solid-state] Mineral form of SODIUM CHLORIDE (NaCl , i.e., table SALT) and is also known as halite. The halite crystalline structure is primarily symmetric (see [Figure R.81](#)).

Figure R.81 Rock salt.

Rods

[biomedical, chemical, optics] Anatomical feature in the EYE responsible for the electrochemical conversion of the luminous intensity (i.e., radiance) of electromagnetic RADIATION in the PERCEPTION of shades of gray (see Figure R.82).

Figure R.82 Radiance sensor: rods of the retina in the eye.

Roemer {Rømer, also Römer}, Olaus (Ole) (1644–1710)

[astronomy, general, optics] Astronomer from Denmark. Ole Roemer concluded that the speed of LIGHT was finite and provided experimental proof with rudimentary equipment of this in 1675, the value obtained was $c = 2.0 \times 10^8$ m/s against the currently accepted value $c = 2.99792458 \times 10^8$ m/s. Roemer used the eclipse one of the largest observable moons of JUPITER, Io, based on the known distance between EARTH and Jupiter at that time. The MEASUREMENT of the speed of light was improved by ARMAND FIZEAU (1819–1896) in 1849 (see Figure R.83).

Figure R.83 Olaus Rømer {Ole Roemer} (1644–1710). (Courtesy of Leonardo Moledo, and portrait by Jacob Coning [circa 1647–1724 dated 1700]; Niels Bohr Institute, Denmark.)

Roentgen, Röntgen

[atomic, nuclear] X-RAY unit. The quantity of X-ray RADIATION which produces 1 esu positive or negative ELECTRICITY cm^{-3} or 3.2083×10^9 ion pairs/ cm^3 of AIR at standard temperature and pressure.

Roentgen, W. C.

[atomic, nuclear] See RÖNTGEN, WILHELM CONRAD.

Roentgen rays

[nuclear] See X-RAY.

Rolling friction

[general] RESISTANCE resulting from deformation of the object or the surface under rolling MOTION. The bulging of automobile tires is a common phenomenon of FRICTION, resulting in an increase in fuel consumption for the automobile, in contrast to solid rubber or low-profile tires. It is also known as “rolling resistance” (see [Figure R.84](#)).

Figure R.84 Rolling resistance examples.

Röntgen, Wilhelm Conrad {Roentgen} (1845–1923)

[atomic, biomedical, general, nuclear, solid-state] Physicist from Germany who described the discovery of X-RAY RADIATION. The discoveries by Röntgen made a remarkable and long lasting impact on solid media imaging, in particular medical imaging. Wilhelm Röntgen observed that the electron beam from a CROOKES TUBE generated other emissions when the electrons collided with the GLASS shell. The released particles were subsequently observed as FLUORESCENCE when exciting the barium platinocyanide coating. Röntgen subsequently recognized that the emitted radiation was capable of traversing paper, aluminum, wood, and other materials, and it would also form a chemical reaction with the photographic plates used for IMAGE formation using visible LIGHT. The new “undefined” X-ray was used to make images of the inside of several objects, including his wife’s hand, showing the bone structure outline on the imprint on the PHOTOGRAPHIC PLATE

consisting of silver chloride. Wilhelm Röntgen received the Nobel Prize in Physics for his discovery in 1901 (see [Figure R.85](#)).

Figure R.85 Wilhelm Conrad Röntgen {Roentgen} (1845–1923).

Rotational (divergence-free) vector field

[computational, fluid dynamics] A fundamental component of HELMHOLTZ DECOMPOSITION in vector calculus. In three-dimensional space, the vector field composed of sufficiently smooth, rapidly decaying vectors can be decomposed into the sum of two “orthogonal” components, one consisting of an IRROTATIONAL (CURL-FREE) VECTOR FIELD and the second segment composed of rotational (divergence-free) or solenoidal vector field (see DIVERGENCE-FREE VECTOR FIELD).

Roughness

[fluid dynamics, mechanics] See SURFACE ROUGHNESS.

Roughness, relative

[fluid dynamics, mechanics] See SURFACE ROUGHNESS.

Rouleaux formation

[biomedical, fluid dynamics] Plural for the French word for roll (i.e., roll of coins) *rouleau*, representative of the forming and maintaining of a stacked red BLOOD CELL in CAPILLARY FLOW (see [Figure R.86](#)).

Figure R.86 Rouleaux formation: stack of red blood cells in small vessel flow.

Rumford, Count (1753–1814)

[general] See **BENJAMIN THOMPSON**.

Runge, Carl David Tolmé (1856–1927)

[computational, general] Mathematician from Germany, known for his collaboration with another German mathematician **MARTIN WILHELM KUTTA** (1867–1944), both involved in the development of the **RUNGA–KUTTA METHOD** (see [Figure R.87](#)).

Figure R.87 Carl David Tolmé Runge (1856–1927).

Runge–Kutta method

[computational, theoretical] Numerical method for integrating nonlinear differential equations and hence providing means to solve them. The mechanism of action uses a conveniently chosen point in the coordinate system that allows integration to minimize the impact of lower order error terms. The method was designed by two mathematicians from Germany (Prussian Empire) CARL DAVID TOLMÉ RUNGE (1856–1927) and MARTIN WILHELM KUTTA (1867–1944) around 1900.

Russell, Bertrand Arthur William (1872–1970)

[general] Mathematician from Great Britain (see [Figure R.88](#)).

Figure R.88 Honorable Bertrand Russell (1872–1970) in 1916.

Russell, Henry Norris (1877–1957)

[nuclear] Astronomer from the United States (see [Figure R.89](#)).

Figure R.89 Henry Norris Russell (1877–1957). (Courtesy of The World's work; published by Doubleday Page, Garden City, New York.)

Russell–Saunders coupling

[atomic, computational, nuclear, quantum] In the orbital MECHANICS of the atomic structure the TOTAL ANGULAR MOMENTUM (J) for the electrons is the result of direct interaction between the ELECTRON SPIN angular momentum (S) and the orbital momentum (L) for that electron. The theoretical description of this phenomenon was developed by HENRY NORRIS RUSSELL (1877–1957) and FREDERICK ALBERT SAUNDERS (1875–1963). The angular momenta associated with the orbital MOTION as well as the SPIN motion can be combined in various manners. The integration of all aspects of these orbital and rotational states for atoms defined by a many electron configuration (Bohr model, Rutherford model) and how they contribute to the ENERGY state definition in a many-electron-atoms depends on three types of interactions: (1) spin–spin coupling, (2) orbit–orbit coupling, and (3) spin–orbit coupling. The two principal coupling schemes identified on a computational level are Russell–Saunders (or L–S) coupling and J–J COUPLING. Under Russell–Saunders coupling it is assumed that the following holds true: spin–spin coupling exceeds the influence over orbit–orbit coupling, which in turn trumps spin–orbit coupling. This approximation holds well for the first column in the table of ELEMENTS, where spin–orbit (J) coupling is relatively small and can be neglected. When the atomic number exceeds thirty (30) the j–j coupling takes precedent due to the fact that spin–orbit coupling becomes more influential. The overall electron spin QUANTUM NUMBER S is the sum of all individual SPIN quantum numbers m_s for the respective electrons, providing spin–spin coupling (first mechanism). The total ORBITAL ANGULAR MOMENTUM quantum number L defines the energy state described by the system composed of electrons, represented by the following terms (second mechanism):

TOTAL ORBITAL MOMENTUM						
L	0	1	2	3	4	5
	S	P	D	F	G	H

The third mechanism of spin–orbit coupling is defined by the resultant of the spin and orbital momenta of each electron which gives yields of the total angular momentum quantum number J . The interaction includes the concept of multiplicity, describing the closely spaced energy levels, defined by the term $(2S + 1)$. The Russell–Saunders expression associated with this coupling is $(2S + 1)L$, which can be described, for instance, using a d^1 electron configuration, where $S = +1/2$, $(2S + 1) = 2$, with respectively $L = 2$ and associated GROUND term 2D . The Russell–Saunders description for the remaining three “ION” configurations are represented as:

R

TERMS FOR THE RESPECTIVE $3d^n$ “FREE” ION CONFIGURATIONS				
CONFIGURATION	NUMBER OF ENERGY LEVELS	NUMBER OF QUANTUM STATES	GROUND TERM	WITH RESPECTIVE EXCITED TERMS:
$d^1; d^9$	1	10	2D	–
$d^2; d^8$	5	45	3F	$^3P; ^1G; ^1D; ^1S$
$d^3; d^7$	8	120	4F	$^4P; ^2H; ^2G; ^2F; 2 \times ^2D; ^2P$
$d^4; d^6$	16	210	5D	$^3H; ^3G; 2 \times ^3F; ^3D; 2 \times ^3P; ^1I; 2 \times ^1G; ^1F; 2 \times ^1D; 2 \times ^1S$
d^5	16	252	6S	$^4G; ^4F; ^4D; ^4P; ^2I; ^2H; 2 \times ^2G; 2 \times ^2F; 3 \times ^2D; ^2P; ^2S$

From this it can be seen that there is congruence between energy levels: d^n gives the same configuration term as d^{10-n} . The ground terms for the electron configurations are derived from Hund's rules: (1) ground term configuration will have maximum value for “multiplicity” and (2) when more than one term with maximum “multiplicity” is available, the ground term will be assigned the largest value for L . Outline of the interpretation of Hund's rule is as follows:

d^n	2	1	0	-1	-2	L	S	GROUND TERM
d^1	↑					2	1/2	2D
d^2	↑	↑				3	1	3F
d^3	↑	↑	↑			3	3/2	4F
d^4	↑	↑	↑	↑		2	2	5D
d^5	↑	↑	↑	↑	↑	0	5/2	6S
d^6	↑↓	↑	↑	↑	↑	2	2	5D
d^7	↑↓	↑↓	↑	↑	↑	3	3/2	4F
d^8	↑↓	↑↓	↑↓	↑	↑	3	1	3F
d^9	↑↓	↑↓	↑↓	↑↓	↑	2	1/2	2D

In order to derive S the values associated with the unpaired electrons need to be summarized using a value of $\frac{1}{2}$ for each. In order to derive L the labels in the respective columns are used to calculate the L value associated with that particular CELL in the table. Subsequently, summarize all respective cells. For instance, for the d^7 configuration the following applies. The +2 box has 2 electrons, yielding for that cell $L = +2 \times 2 = +4$; while the +1 box occupies 2 electrons, with respectively $L = +1 \times 2 = +2$, henceforth the 0 box has 1 electron: $L = 0$, the -1 box is 1 electron with $L = -1$, and finally the -2 box with 1 electron yields $L = -2 \times 1 = -2$, respectively $L = +4 + 2 + 0 - 1 - 1 = 3$. Note under the configuration of 5 electrons with 1 electron in each cell $L = 0$. The latter entails that the L -value for a d^1 configuration has the same configuration as for a d^6 . Alternatively, substitution of electrons with “holes” provides a platform to equate alternative electron configurations, such as conforming a d^1 configuration to a d^9 condition, where the d^1 case has one (1) electron and the d^9 case has a hole (i.e., absence of electron). From the L–S table it can be derived that there are 4D ground terms configurations (d^1, d^4, d^6, d^9). Similarly the F ground term has four configurations: (d^2, d^3, d^7, d^8), while the d^5 configuration provides for an S ground term (*also see L–S COUPLING*) (see Figure R.90).

Figure R.90 Diagram representing Russell–Saunders coupling.

Rutherford, Ernest (1871–1937)

[general, nuclear, solid-state, thermodynamics] Scientist from New Zealand, apprentice of JOSEPH JOHN THOMSON (1856–1940); 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson. Recipient of the Nobel Prize in Chemistry in 1908. During his research in BECQUEREL RADIATION (the phenomenological description of radioactivity as discovered by HENRI BECQUEREL, 1852–1908, in 1896) he discovered the ALPHA PARTICLE (α) and defined the BETA PARTICLE (β). Rutherford is generally recognized as the leader in experimental nuclear PHYSICS. The PROTON was identified/postulated by WILHELM WIEN (1864–1928) in 1898, and named by Ernest Rutherford in 1920. The major contributions of Ernest Rutherford are the description of the nuclear HALF-LIFE and the conversion from one ELEMENT to another during NUCLEAR DECAY (see [Figure R.91](#)).

Rutherford cross section

[atomic, nuclear] Respective scattering CROSS SECTION (finite size $d\sigma_s$) into a SOLID ANGLE ($d\Omega$) for the interaction with a PROJECTILE charged PARTICLE with a NUCLEUS with “size” (charge distribution related, the atomic number $[Z]$ multiplied with the proton charge $[e]$: Ze) with respect to an incident charge particle with atomic number Z_1 and velocity v_0 : $d\sigma_s/d\Omega = (Z_1 Z_2 e^2 / 8\pi\epsilon_0 m_\alpha v_0^2)^2 \csc^4(\theta/2)$, with the electron charge: $e = 1.60217657 \times 10^{-19} \text{C}$, the permittivity of free space: $\epsilon_0 = 8.85419 \times 10^{-12} \text{C}^2/\text{Nm}^2$, m_α the mass of the incident particle, the ALPHA PARTICLE, at deflection angle θ .

Rutherford scattering

[atomic, quantum] Based on the PARTICLE scattering distribution of Ernest Rutherford’s (1871–1937) bombarding of a gold foil with ALPHA PARTICLES, described as the ANGLE between the incident velocity of an alpha particle and the respective scattered velocity. The SCATTERING probability distribution as a function of the size of the NUCLEUS under target (i.e., the total charge; determined from the atomic number [“proton number”]: Z) for a charged PROJECTILE traveling with incident velocity v_0 , and mass m_α is presented in an angular (scattering angle: θ) representation as $P(\theta) = n(\theta)/n_0 = [Z_\alpha^2 Z^2 e^4 / 4(4\pi\epsilon_0)^2 m_\alpha^2 v_0^4] [1/\sin^4(\theta/2)]$, with the unit “electron” charge (identical for the PROTON, but opposite sign): $e = 1.60217657 \times 10^{-19} \text{C}$, the permittivity of free space: $\epsilon_0 = 8.85419 \times 10^{-12} \text{C}^2/\text{Nm}^2$, m_α the mass of the alpha particle (or in general the incident particle, with number of negative charges: Z_α), and v_r the recoil velocity of the nucleus. For the preverbal gold foil with thickness d_f and n_g gold atoms per unit volume, this translates into the angular probability ($N(\theta)$) for the collection of the number of scattered alpha particles ($N(\theta)$) at a return angle (θ), from a DISTANCE to the target nucleus (r), with respect to the incident beam of N_i alpha particles, each with kinetic ENERGY ($\text{KE}_\alpha = (1/2)m_\alpha v_0^2$) as $N(\theta) = (N_i n_g d_f Z^2 k_C^2 e^4 / 4r^2 \text{KE}_\alpha^2) [1/\sin^4(\theta/2)]$, with the Coulomb’s constant: $k_C = 1/4\pi\epsilon_0$, where: $\epsilon_0 = 8.85419 \times 10^{-12} \text{C}^2/\text{Nm}^2$ the permittivity of free space. The scattering concept provide a means to derive the size of the nucleus based on the “closest approximation distance” (d_0) for the incident charge with respect to the nucleus. At the closest approach the kinetic energy will be totally converted in potential energy for a brief moment, where the potential energy is the Coulomb energy: $U_p = (1/4\pi\epsilon_0)(Z_\alpha Z e^2 / d_0)$, which yields: $d_0 = (1/4\pi\epsilon_0)(Z_\alpha Z e^2 / mv_0^2)$. The closest distance of approach revealed deviations from a pure proton nucleus, and in 1920 the NEUTRON was introduced hypothetically by Rutherford, which was verified in 1932 and generally accepted in 1935 (see Figure R.92).

Figure R.92 Diagram representing the early concept of Rutherford scattering from the early 1900s.

Rutherford's atom

[general, nuclear, solid-state, thermodynamics] The ATOM consists of two main components: the NUCLEUS and orbiting "PLANET" electrons. This model was developed in parallel with the BOHR ATOMIC MODEL (see [Figure R.93](#)).

Figure R.93 Rutherford's "planetary" atom model.

Rydberg, Johannes Robert (1854–1919)

[atomic, nuclear] Physicist from Sweden. Johannes Rydberg provided elementary details about atomic structure and ENERGY configuration. Rydberg specifically introduced a constant that labeled the energy transitions used by various experimentalists, the RYDBERG CONSTANT. The Rydberg constant is used in the RYDBERG SERIES, and the BALMER SERIES, Humphreys series, LYMAN SERIES, PASCHEN SERIES, and PFUND SERIES (see [Figure R.94](#)).

Figure R.94 Johannes Robert Rydberg (1854–1919).

Rydberg constant

[atomic, general, nuclear, solid-state, thermodynamics] Fundamental constant describing the relationship between WAVELENGTH and ATOMIC NUMBER of an ATOM in the ELECTRON ENERGY TRANSITIONS occurring at the inner level of the BOHR ATOMIC MODEL, generating CHARACTERISTIC X-RAY RADIATION: $R_{\text{Ry}} = 1.097373 \times 10^7 \text{ m}^{-1}$. The value was derived by the Swedish scientist JOHANNES ROBERT RYDBERG (1854–1919) around 1890.

Rydberg series

[atom] Atomic ELECTRON DECAY introduced in 1888 by JOHANNES ROBERT RYDBERG (1854–1919) in general denomination, but primarily geared to hydrogen as

$$\frac{1}{\lambda} \Big|_{\text{vacuum}} = R_{\text{Ry}} \left[\left(\frac{1}{n_1^2} \right) - \left(\frac{1}{n_2^2} \right) \right] \xRightarrow{\text{generalized}} R_{\text{Ry}} Z^2 \left[\left(\frac{1}{n_1^2} \right) - \left(\frac{1}{n_2^2} \right) \right],$$

describing the decay RADIATION with wavelength λ emitted by the ENERGY lapse for an electron traversing from orbit n_2 to orbit n_1 ($n_1 < n_2$), with higher “BINDING” ENERGY, with RYDBERG CONSTANT $R_{\text{Ry}} = 2\pi^2 k_B^2 e^4 m_e Z^2 / b^3 c = 1.097373 \times 10^7 \text{ m}^{-1}$ $Z = 1$ for (Boltzmann coefficient $k_B = 1.3806488 \times 10^{-23} \text{ m}^2 \text{ kg/s}^2 \text{ K}$, electron charge: $e = 1.60217657 \times 10^{-19} \text{ C}$, electron mass: m_e , PLANCK’s CONSTANT: $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$, and c the speed of LIGHT), and Z the charge of the hydrogen-like ATOM (see Figure R.95).

Figure R.95 Rydberg series for lithium. (Courtesy of DJ Indica.)

Rydberg state

[atomic, general, solid-state] Excited electron state in an ATOM or MOLECULE that provides an isolated energetic condition for that electron, resembling the state of an electron in a HYDROGEN ATOM. The electron acting as if it were a free electron has DECAY stages that have an ENERGY transfer resembling the RYDBERG SERIES.

Rytov, Sergei M. [РЫТОВ, Сергей Михайлович] (1908–1996)

[acoustics, computational, mechanics] Mathematician from the United Soviet Republic (USSR; now Russia). Sergei Rytov was best known for his PERTURBATION THEORY and WAVE propagation description with respect to nonuniform media (see [Figure R.96](#)).

Figure R.96 Sergei M. Rytov (1908–1996). (Courtesy of Kotelnikov Institute of Radio Engineering and Electronics, Russian Academy of Sciences, Moscow, Russian Federation.)

Rytov approximation

[acoustics, computational] Ultrasonic TOMOGRAPHY algorithm using a perturbation of the PHASE of the WAVE in the WAVE EQUATION. Introduced by SERGEI RYTOV (1908–1996). This is of importance based on the assumption that wave transport will suffer DISPERSION due to inhomogeneities, specifically what is providing information about the acoustic parameters of the media in transit for the pressure wave ($P(\vec{r}, \nu)$), as a function of location $\vec{r}$ and frequency ν . In the wave equation the phase ($\phi(\vec{r}, \nu)$) of the pressure wave field is defined as $\phi(\vec{r}, \nu) \equiv \log_{10} P(\vec{r}, \nu)$. When an acoustic source $w(\vec{r}'', \nu)$ (acoustic perturbation with respect to location in second-order derivative) is applied the dispersion is captured as the reciprocal speed of propagation: $\vec{s}(\vec{r}, \nu) = 1/\vec{v}(\vec{r}, \nu)$. The acoustic propagation adheres to the wave equation: $[1/\vec{v}(\vec{r}, \nu)^2](\partial^2/\partial t^2)P(\vec{r}, \nu) - \nabla^2 P(\vec{r}, \nu) = w(\vec{r}, \nu)$, $w(\vec{r}, \nu)$ defining the VELOCITY POTENTIAL and DIVERGENCE. The unperturbed situation is described by $[1/\vec{v}(\vec{r}, \nu)^2](\partial^2/\partial t^2)P_0(\vec{r}, \nu) - \nabla^2 P_0(\vec{r}, \nu) = 0$. The wave equation has standard Green's functions as solutions: $G(\vec{r}, \vec{r}'', \nu)$; respectively $G(\vec{r}, \vec{r}', \nu)$ and $G(\vec{r}', \vec{r}'', \nu)$, in locations $\vec{r}$; $\vec{r}'$; $\vec{r}''$. The phase perturbation ($\partial\phi(\vec{r}, \nu)$) is now defined as $\partial\phi(\vec{r}, \nu)/\partial\vec{s}(\vec{r}', \nu) = \iiint 8\pi^2 \nu^2 \vec{s}(\vec{r}, \nu) G(\vec{r}, \vec{r}', \nu) G(\vec{r}', \vec{r}'', \nu) w(\vec{r}'', \nu) d^3\vec{r}'' / \iiint G(\vec{r}, \vec{r}''', \nu) w(\vec{r}''', \nu) d^3\vec{r}'''$. This yields for the pressure wave: $P(\vec{r}, \nu) = [1/\vec{v}(\vec{r}, \nu)^2](\partial^2/\partial t^2) \iiint \eta_c P_0(\vec{r}', \nu) G_0(\vec{r}', \vec{r}'', \nu) d^3\vec{r}''$, with η_c the “susceptibility” of the medium (“COMPLIANCE”) and $G_0(\vec{r}', \vec{r}'', \nu) = G_0(\vec{r}' - \vec{r}'', \nu)$ the Greens function SOLUTION to the unperturbed situation, in first-order approximation. In contrast the Born approximation uses perturbation of the AMPLITUDE.

S

S

[general] **DISTANCE** vector used in description of displacement $[\vec{s}]$. The absolute value is the **SCALAR** value of displacement, while the imaginary part describes the direction (see [Figure S.1](#)).

Figure S.1 s-vector.

S, M, and L responses of the human eye

[biomedical, general, optics] Layman's description of the **COLOR** vision by three sets of **CONES**: Short (-wavelength), *Medium* (-wavelength) and *Long* (-wavelength) representing the blue, green and **RED** cones (*also see VISION and see RETINA*).

Saberian number (Sa =)

[fluid dynamics] Dimensionless number signifying the **LIQUID** fraction applying to two-phased flow. The Saberian number is an indication of the "ease" with which a drop can be formed. Also applies to **SIGNAL** processing in neural networks.

Sabine equation

[acoustics, biomedical] Theoretical description of the time scale (reverberation time: RT) to allow a **SOUND** reverberating in a closed environment (volume V) to reduce by 60 dB while reflecting of walls with attenuation $\mu_{s,a}$, defined as $RT = k_s (V / \mu_{s,a})$, where k_s is the temperature dependence for the **WAVE** interaction. The temperature coefficient has been established to be $k_s = 0.161$ for a room temperature of 22°C.

Saccade

[biomedical, electronics, theoretical] Short deliberate movement across the field of view outlined by the azimuthal and the polar ANGLE in a spherical coordinate system. The saccade MOTION is regulated by the brain but is not necessarily something that is controlled by the desire of the subject. The duration of these EYE movement generally ranges from 100 to 300 ms and ranges over several degrees of rotation. The movement is both voluntary and involuntary, in contrast to the solely involuntary MICROSACCADE. The saccade can be a response to an incident in the peripheral VISION that makes the brain aware of a change in the status-quo that deserves attention, which can be considered a defense mechanism but also falls under the deliberate focusing of attention during a quick survey of one's perimeter. The main reason for saccade motion is avoiding "burn-in," where a group of RODS and CONES may get saturated from continued exposure and as a result will adjust their sensitivity down (sometime to the point of not detecting LIGHT anymore). In case SATURATION of the RETINA is induced the rods and cones become insensitive to exposure and form a risk of not being able to detect threats or challenges. Under strict concentration one can force the eyes to stay targeted without performing saccade motion (*also see MICRO-SACCADE*) (see [Figure S.2](#)).

Figure S.2 Saccade motion of the eye. One way of observing this saccade motion yourself is with the use of an older model LED display calculator (Note: LCD screens do not blink and the visual aspect is hence not obvious). Looking straight forward (not following the calculator itself) move the calculator with at least one single display light-up in a straight up and down motion and the blinking lights will trace-out a curvy path up-down.

Saha, Meghnad (1893–1956)

[electronics, nuclear, thermodynamics] Indian astrophysicist. Saha's work describes the chemical and electronic balance in compounds as well as stellar structures including galactic dust. The ENERGY balance is defined by the Saha equation (see Figure S.3).

Figure S.3 Meghnad Saha (1893–1956).

Saha ionization equation

[astrophysics, electronics, nuclear, thermodynamics] Also Saha ionization equation, or Saha-Langmuir equation, developed by the Indian physicist MEGHNAD SAHA (1893–1956) in 1920. The Saha-equation describes the ratio of free charges to the number of electrons bound in atomic form, the IONIZATION fraction: $[\rho_e(x)\rho_i(x)]/\rho_a(x) = (1/nh^3)(2\pi m_e kT)^{2/3} e^{-[I/(kT)]}$, with $\rho_*(x)$ the ELECTRIC CHARGE density for the electrons ($* = e$), atoms ($* = a$) and ions ($* = i$) respectively and $I = (Z/n^2)(-13.6eV)$ the IONIZATION ENERGY, n the electron level in the BOHR ATOMIC MODEL, $k = 1.3806503 \times 10^{-23} \text{ m}^2 \text{ kgs}^{-2} \text{ K}^{-1}$ the Boltzmann constant, T temperature in Kelvin, m_e electron mass, and $h = 6.626068 \times 10^{-34} \text{ m}^2 \text{ kgs}^{-1}$ PLANCK'S CONSTANT.

Sahl, Ibn (Arabic: سهل ابن) (Abu Sa'd al-'Ala'ibn Sahl) (940–1000)

[mathematics, optics] Physicist and mathematician from Iraq, at the time known as Persia. The work of Ibn Sahl describes the LAW OF REFRACTION in a similar manner as attributed to WILLEBRORD SNEL (SNELLIUS) VAN ROYEN (1591–1626) (see [Figure S.4](#)).

Figure S.4 Artist impression of what Abu Sa'd al-'Ala' ibn Sahl (940–1000) may have looked like.

Saint-Elmo's fire

[atomic, energy] CORONA or charge streamer from a narrow pointy object (needle-like) such as the mast of a ship. It has also been observed on planes and in particular on helicopters, during the war in Afghanistan and was named Kopp–Echells effect by the photographer in honor of two soldiers who lost their lives there (see [Figure S.5](#)).

Figure S.5 Saint-Elmo's fire on top of a roof. (Courtesy of Joe Thomissen.)

Salt

[chemical, general] Chemical binding between a METAL and a halogen occurring in crystalline form as a solid and dissolves as ions in water. The most well-known salt is sodium chloride, or kitchen salt: NaCl.

SAM

[acoustics, biomedical] Imaging device based on the probing by focused MECHANICAL WAVE patterns. The propagation of SOUND through solids is a function of the local elastic properties, specifically the acoustic impedance which is a function of the wavelength of the density wave and the temperature next to the medium itself. The pressure wave or stress-wave propagation is indicated by the AMPLITUDE of the pressure at a point in the path of the WAVE. The migration of the stress wave is confined by the mechanical attributes of the media, that is, localized COMPLIANCE ($C = \partial V / \partial P$) or Young's modulus (E_{mech}) as a function of location. The time factor describing the propagation is called stress confinement or stress RELAXATION TIME, $\tau_s = \delta / V_a$, where V_a is the speed of sound in tissue. The acoustic transmission through the tissue layers is governed by the acoustic impedance, Z , a quantity defined as a product of density, ρ (tissue, temperature) and sound velocity, $v(v) = \sqrt{E_{\text{mech}} / \rho}$, yielding $Z = \rho v$ for the acoustic impedance. The acoustic impedance has a dispersive relation in inhomogeneous tissue, providing one of the elementary tools for diagnostic sensing. The RESOLVING POWER is directly proportional to the half wavelength of the probing sound wave. The sound is reflected from boundaries and dispersed and scattered to be analyzed by means of path reconstruction by means of time of flight measurements from array type sensor configurations (see SCANNING ACOUSTIC MICROSCOPE) (see Figure S.6).

Figure S.6 Intensity profile image obtained by scanning acoustic microscope. (Courtesy of Ronald D. Kriz.)

Sampled delay focusing

[acoustics, computational] Ultrasonic BEAM-FORMING technique used with PHASED ARRAY pressure source which enables the emission of the SOUND WAVE to be confined within a narrow SOLID ANGLE (see PHASED-ARRAY).

Sampling

[acoustics, computational, electromagnetism, optics] The process of collecting data points. The sample data collection may be continuous or event-triggered. The limiting factor for discrete, periodic events (both spatial and temporal) is the minimum sampling rate, which is defined by the Nyquist sampling rate, or NYQUIST-SHANNON SAMPLING THEOREM. The minimum sampling rate used for a periodic event was defined

by HARRY NYQUIST (HARRY THEODOR NYQVIST; 1889–1976) and CLAUDE SHANNON (1916–2001) to be twice that of the minimum limit on the occurrence of an event within an observation composed of several events. The Nyquist sampling rate will provide two data-points for the definition of the location (i.e., spatial) or duration (resp. temporal) of a single event.

Sampling depth

[acoustics, computational, electromagnetism, optics] The depth from which SIGNAL is collected that has a signal to NOISE (background) ratio that provides useful information for accurate signal processing, meaning the phenomenon that is probed can be identified with scientific and clinical diagnostic limits of acceptance. Depending on the probing source configuration the sampling depth can range from micrometers to meters.

Sarcomere

[biomedical, chemical, mechanics] Elementary contraction unit in skeletal and HEART muscle. A MUSCLE fiber (e.g., SKELETAL MUSCLE) is a thin elongated cylinder with rounded ends and may extend the full length of the muscle. Beneath its sarcolemma (CELL MEMBRANE), the cytoplasm or sarcoplasm of the fiber contains many small, oval nuclei and MITOCHONDRIA. Within the sarcoplasm are numerous threadlike myofibrils that lie parallel to one another. They play an important role in muscle contractions. The myofibrils contain two kinds of protein filaments, thick ones composed of the protein MYOSIN and thin ones composed of the protein ACTIN. The arrangement of these filaments in repeated units are called sarcomeres, which produce the characteristic alternating LIGHT and dark striations of muscles. Light areas are the I-bands and the darker areas are A-bands. Z-lines are where adjacent sarcomeres come together and thin myofilaments of adjacent sarcomeres overlap slightly. Thus, a sarcomere can be defined as the area between Z-lines. Myosin filaments are located primarily within the dark portions of the sarcomeres, while actin filaments occur in the light areas (*see* MUSCLE) (*see* Figure S.7).

Figure S.7 Light microscopy magnified image of sarcomere in muscle.

Satellite

[astrophysics/astronomy, general] Word for artificial object launched from EARTH in orbit or at least in PROJECTILE motion horizontal to the earth's surface. The word "satellite" was introduced by JOHANNES KEPLER (1571–1630). Kepler's initial description of satellite MOTION were based on a model of a flat Earth, yielding a

parabolic trajectory. With current knowledge and verified ORBITS this is showing that all motions in space are primarily ellipsoids. The first EARTH SATELLITE defined as an electronic medium relaying signals from space to the Earth or from one location on Earth to another location beyond the horizon, was the Newton. Probably the most well-known satellite is the Russian (then USSR) space communication device Sputnik. Other applications are in observation (spy satellite, and METEOROLOGY). Satellites generally have no means of correction and are presumably placed in a geo-stationary or GEOSYNCHRONOUS ORBIT. However, due to gravitational pull and interaction with space debris the satellite may eventually return to Earth (see [Figure S.8](#)).

Figure S.8 Satellite: (a) Sputnik and (b) detail of general satellite in orbit around Earth.

Saturable nuclear force

[general, nuclear] One NUCLEON particle can only influence a limited number of closely neighboring particles, primarily based on the fact that the nucleon is totally surrounded by other nucleons, except for the nucleons at the “surface” of the NUCLEUS of the ATOM. This phenomenon is part of the short-range NUCLEAR FORCE.

Saturated state

[thermodynamics] A condition where the conditions would under normal conditions result in condensation (GAS) or AGGREGATION (dissolved SOLUTE) but due to the absence of condensation points refrains from changing state. For instance low temperature steam derived from cooling SUPERHEATED STEAM. The saturated state can be formulated by the EQUATION OF STATE for the equilibrium.

Saturated vapor pressure

[general] Situation where the GAS pressure of a medium is greater than the pressure in the LIQUID form of the medium at the boiling point. This condition may be achieved in a closed container. VAPOR PRESSURE increases with temperature, until at equilibrium the liquid comes to a boil. The liquid-GAS PHASE diagram as a function of volume of the container and the pressure at various temperatures is expressed in the Van der Waals diagram, supported under the Van der Waals equation (see PHASE DIAGRAM).

Saturation

[biomedical, chemical, mechanics, optics, thermodynamics] Critical range or point above which there is no linear increase of the parameter, identifying a maximum in the distribution function. In SOLUTION once saturation is reached the solutes start to crystallize and dissociate from the SOLUTE. When a force is in saturation there will be no increase in velocity. Under magnetization when saturation is reached there is no further increase in the MAGNETIC FIELD of the magnetic material. Soil acting as a sponge can only contain a

certain amount of LIQUID, where saturation sets in, above this point additional liquid will drain from the sponge, resulting in flooding. In visual PERCEPTION saturation of COLOR will indicate the “richness” of the perceived spectral profile of a source, which may be due to either illumination or pigment quantity content. A saturated GAS will precipitate a condensate, most well-known is fog and associated RAIN. In an IONIZATION chamber the production of ions can be saturated once the applied voltage captures all the produced ions without inducing additional ionization. In semiconductor operations an NPN TRANSISTOR can become saturated when the collector voltage is set at a level that is lower than the base voltage, hence making the collector change to emitter and the function of the TRANSISTOR is saturated. In a gas discharge the type of discharge will be regulated by the applied current, switching from GLOW-DISCHARGE to ARC DISCHARGE when a threshold is exceeded. In thermodynamic terms for instance water VAPOR at a certain temperature can be out of equilibrium with water, creating super-heated steam, or yielding condensation. Additional saturation in chemistry pertains to the maximum of chemical bonds created, or the maximum number of molecular products (see Figure S.9).

Figure S.9 (a–b) Saturation.

(Continued)

Figure 5.9 (Continued) (c-d) Saturation.

Saturation curve

[biomedical, mechanics, meteorology, thermodynamics] The SATURATION vapor curve describes the equilibrium between LIQUID and VAPOR in the T-S diagram, where T represents the temperature and S the entropy of the system. Alternatively the Michaelis-Menten saturation curve describes the chemical interaction in an enzymatic reaction, illustrating the plateau reached in the chemical reaction rate after a certain chemical quantity has been converted, resembling the charge curve of a CAPACITOR with an exponential/logarithmic temporal response. In biology the Oxygen binding to hemoglobin has a saturation leveling-off as a function of the partial pressure of the SOLUTE oxygen transferred in the alveoli of the lung into the blood-stream. The oxygen saturation is indicated by the Hüfner's constant ($\xi_{\text{Hüfner}} = 1.34$). BLOOD has a theoretical maximum capacity of binding oxygen of $= 1.39$ mL/gr. Additionally STRAIN-GAUGES have a response time that saturates when plotting the deformation (i.e., DISTANCE or arc) versus time. In geothermal applications

the formation of fog follows the RELATIVE HUMIDITY and the local temperature with respect to the rate in which fog is formed. In ELECTRONICS the response of an electronic circuit is plateauing as a function of frequency in alternating current drives such as RADIO frequency, radio, or television where the output at a certain point does no longer increase linearly with the driver input. A related principle applies to the charge accumulation on a capacitor as a function of time. An entirely different saturation is found in hydrocarbon AGGREGATION in the EARTH'S CRUST subsurface terrain. Hydrocarbon gasses and liquids are confined in four modes in particular: (1) GAS or OIL in volume storage, (2) oil or gas droplets in isolated form (e.g., suspended in gasses or on a surface, for instance through SURFACE TENSION), (3) hydrocarbon as solute in various liquids, and (4) suspended in kerogenous (porous) rocks. Specifically the dissolved and aggregated form of hydrocarbon content has a saturation curve per unit medium (see Figure S.10).

Figure S.10 Saturation curve diagram.

Saturation dome

[thermodynamics] Dome shaped relationship for the liquid-vapor equilibrium in a pressure–volume diagram (P–V diagram) with respect to temperature (see Figure S.11).

Figure S.11 Graphical representation of a saturation dome.

Saturation pressure

[thermodynamics] The optimal equilibrium pressure between LIQUID and saturated VAPOR in a confined environment (e.g., sealed container). The saturation pressure is a function of temperature, and volume as well as quantity of liquid (*see* PHASE DIAGRAM).

Saturn

[astrophysics/astronomy, general, mechanics] Sixth planet orbiting the SUN in our SOLAR SYSTEM, and second largest. The PLANET Saturn is the only planet with a seemingly infinite number of particles orbiting, compared the single MOON orbiting the third planet EARTH. Saturn has additionally in excess of 30 moons orbiting. The debris is held in orbit by gravitational pull. The galactic dust appears to form several confined rings of material grouping together. The rings of Saturn perform a WAVE MOTION similar to a tidal action which is one of the mechanisms that keeps the rings from coalescing. Note that most planets, moons, and comets form elliptic ORBITS for the reduction of stored angular momentum and rotational kinetic ENERGY to balance against the potential energy of the gravitational attraction in addition to minimal moment-of-inertia. Saturn revolves around the Sun in 29.42 earth-years, whereas its own revolution is 10.2 earth-hours. Due to the enormous angular velocity the planet is compressed the most out of all in the solar system with ellipsoidal ratio, oblateness: $R_{\text{oblate}} = (r_e - r_p)/r_e = 0.098$, where r_e is the equatorial radius and r_p the polar radius with equatorial diameter 120,540 km, whereas for Earth $R_{\text{oblate}} = 0.003353$. The mass of Saturn is $m_{\text{Saturn}} = 5.69 \times 10^{26}$ kg with a low density of $\rho_{\text{Saturn}} = 0.70 \text{ kg/m}^3$ (*see* Figure S.12).

Figure S.12 Planet Saturn.

Saunders, Frederick Albert (1875–1963)

[computational, nuclear] Optical scientist and physicist from Canada, focused on SPECTROSCOPY. The work of Fredrick Saunders and HENRY NORRIS RUSSELL (1877–1957) describes the spectroscopic results from a specific atomic configuration that has more than one VALENCE electrons in the outer most shell (as described by the BOHR ATOMIC MODEL) that produce the spectral lines resulting from absorption and emission. The phenomenon is called RUSSELL-SAUNDERS COUPLING spectroscopy. Due to the plural electron configuration there are two momenta involved, the orbital (identified by the parameter L) and angular rotational SPIN (identified by the parameter S), hence also called L – S COUPLING.

Sauveur, Joseph (1653–1716)

[acoustics, computational, general, mechanics] computational physicist and mathematician from France. Even though he was deaf, his interest in the VIBRATION aspect of SOUND waves lead him to recognize that the RESONANCE FREQUENCY (ν) of a vibrating object primarily depended on the mass per unit length (m_l) next to the spring constant (k_{mech}) or ELASTICITY in deformation: $\nu = 1/2\pi \int_0^l \sqrt{(k/m_l)} dl$. His pioneering efforts in ACOUSTICS are known for the introduction of the concepts of FUNDAMENTAL FREQUENCY, harmonics, and node (see [Figure S.13](#)).

Figure S.13 Joseph Sauveur (1653–1716).

Savart, Félix (1791–1841)

[acoustics, electromagnetism, energy, general, mechanics] Physicist, medical doctor and engineer from France. He contributed to the understanding of ACOUSTICS as well as the behavior of magnetic fields and their interaction with paramagnetic materials. Together with JEAN BAPTISTE BIOT (1774–1862) they described the behavior of magnetic objects in a changing magnetic field, more precisely the MAGNETIC FIELD (B) distribution in space ($\vec{r}$) generated by a steady-state current ($\vec{I}$) flowing through a CONDUCTOR is known as the BIOT-SAVART LAW: $B = \mu_0 / 4\pi \int (\vec{I} \times \vec{r} / |\vec{r}|^3) dI$ for an integral over the length (l) of a conductor, where μ_0 is the DIELECTRIC permeability of VACUUM. Beyond the validity of the boundary conditions of the Biot–Savart approximation the JEFIMENKO'S EQUATIONS are the tools of the trade (see [Figure S.14](#)).

Figure S.14 Félix Savart (1791–1841).

Savery, Thomas (1650–1715)

[general, mechanics] “Captain Savery.” Inventor of a steam driven water pump ENGINE in 1698, the principle was based on the concept of the PRESSURE COOKER presented by DENIS PAPIN (1647–1712) from 1679, also called a Digester. The PUMP was designed to use VACUUM technique to pump water out of coal mines, however unsuccessful due to the limitations in height that could be overcome by the steam-vapor driven suction. Condensation of the water VAPOR at the raised outlet created a low level vacuum that pulled liquids upwards for discharge. Savery later teamed up with THOMAS NEWCOMEN (1664–1729), in collaboration with JOHN CALLEY (1644–1725), to develop the atmospheric reciprocating steam engine in approximately 1710. Other inventions by Savery include a mechanism to measure DISTANCE traveled for ships, also called an odometer for ships (see [Figure S.15](#)).

Figure S.15 Thomas Savery (1650–1715).

SAW

[acoustics] See SURFACE ACOUSTIC WAVE.

Scaffold

[biomedical, mechanics] In regenerative MEDICINE scaffolds are used to “grow” organs on, as internal permanent or biodegradable matrices. By carefully selecting the chemical structure of the materials that make up the fabric of the scaffold, CELL will adhere to the scaffold, forming a three-dimensional biological structure that conforms to the geometry of the scaffold as well as the genetic predisposition that can be implanted as a messenger to result in the formation of a single biological feature that can be used for transplant surgery. The natural scaffolds in biology are collagen and epithelial cells. Since the building blocks (i.e., cellular fundamentals from stem-cell sources) are from the person for whom the novel biological feature grown on the scaffold is intended for there will be minimal risks for rejection as a foreign body. Another particular application of biological scaffolds is in vascular grafts and prosthetics. The scaffold can be designed to disintegrate or remain intact, depending on the intended function and mechanical

requirements. In mechanical ENGINEERING a scaffold is also a mechanical construction that in this case allows for access to a structural formation, such as a building or an artwork that reaches above the reach of the people working on it (see [Figure S.16](#)).

Figure S.16 Scaffold: (a) organ scaffold used in regenerative medicine to grow an arrangement of various tissues in a specified configuration and (b) metal building scaffold.

Scalar

[computational, general] Magnitude without direction, quantity. The alternate use would be a vector, which has both MAGNITUDE and direction.

Scanning acoustic microscope (SAM)

[acoustics, biomedical, mechanics] Imaging device based on the probing by focused MECHANICAL WAVE patterns. The propagation of SOUND through solids is a function of the local elastic properties, specifically the acoustic impedance which is a function of the wavelength of the density wave and the temperature next to the medium itself. The pressure wave or stress-wave propagation is indicated by the AMPLITUDE of the pressure at a point in the path of the WAVE. The migration of the stress wave is confined by the mechanical attributes of the media, that is, localized COMPLIANCE ($C = \partial V / \partial P$) or Young's modulus (E_{mech}) as a function of location. The time factor describing the propagation is called stress confinement or stress relaxation time, $\tau_s = \delta / V_a$, where V_a is the speed of sound in tissue. The acoustic transmission through the tissue layers is governed by the acoustic impedance, Z , a quantity defined as a product of density, ρ (tissue, temperature) and sound velocity, $v(v) = \sqrt{E_{\text{mech}} / \rho}$, yielding $Z = \rho v$ for the acoustic impedance. The acoustic impedance has a dispersive relation in inhomogeneous tissue as well as composite materials, providing one of the elementary tools for diagnostic sensing. The RESOLVING POWER is directly proportional to the half wavelength of the probing sound wave. The sound is reflected from boundaries and dispersed and scattered to be analyzed by means of path reconstruction by means of time of flight measurements from array type sensor configurations. The incident acoustic wave used in mechanical acoustic microscopy can be generated by piezoelectric devices and requires focusing techniques to enhance the RESOLUTION, since the resolution will be restricted by the width of the acoustic beam. The mechanically produced

acoustic wave will need to be coupled into the imaging medium by means of a medium that provides acoustic impedance matching. The use of water is routine, however liquid helium can significantly enhance the LATERAL RESOLUTION by an order of MAGNITUDE. The acoustic SIGNAL retrieval is primarily performed by piezoelectric sensing arrays. The use of large APERTURE acoustic lenses for signal retrieval can provide radial resolution enhancement through INTERFERENCE inside the “LENS.” The reconstruction process is based on inverse SCATTERING theory and time-resolved detection used for phase analysis. A Scanning Laser Acoustic Microscope (SLAM) uses a pulsed laser to generate the acoustic pulses (photoacoustic effect) resulting from localized EXPANSION due to the absorption of LIGHT, and the laser is scanned across the medium under interrogation for a three-dimensional reconstruction of the mechanical properties. As in ULTRASONIC IMAGING the operating FREQUENCY SPECTRUM is in the MHz to GHz range. Based on the scanning laser acoustic microscope another modality was added with special emphasis on the PHASE detection of the acoustic wave resulting in the Scanning tomographic acoustic microscope (STAM); also found as Scanning Acoustic Tomography (SAT). Due to the random phase of the acousto-optical pulse the constraints for the tomographic imaging are in the theoretical analysis and the use of multiple arrays of sensors to perform scattered wave reconstruction, based on both time-of-flight and phase-sensitive detection. Acoustic microscopy can be used for nondestructive testing, revealing the REFLECTION from MICROSCOPIC cracks and stress and strain anomalies (*also see PHOTOACOUSTIC IMAGING*) (see Figure S.17).

Figure S.17 Scanning acoustic microscope design and implementation.

Scatchard, George (1892–1973)

[biomedical, chemical] Scientist and chemist from the United States. Scatchard made significant contributions in physical chemistry of solutions. He focused on the theoretical explanation of steady-state solutions in equilibrium and nonsteady-state solutions, ranging from simplest mixtures of nonpolar molecules to

systems containing polar molecules of various degree as well as ions, and he also included MACROMOLECULES, specifically the unexplored area of proteins (see Figure S.18).

Figure S.18 George Scatchard (1892–1973). (Courtesy of Chemical Heritage Foundation, Philadelphia, PA.)

Scatchard equation

[biomedical, chemical] Formulation of the LIGAND affinity to the distribution of various proteins. $r_{l_b}/c_l = nK_a - rK_a$, where r_{l_b} is the ratio of the concentration of bound ligand to the number of available binding sites, c_l the free ligand concentration, $K_a = [A_b - A_g]/([A_b][A_g])$, where $1/K_a$ is the slope and is the affinity constant, with $[A_b]$ the concentration of antibody binding-sites, $[A_g]$ the antigen concentration (monovalent), $[A_b - A_g]$ the concentration of antigen bound to anti-body, and n is the number of binding sites per protein MOLECULE. Introduced by GEORGE SCATCHARD (1892–1973). This expression is equivalent to the one of the three linear transformations of the MICHAELIS-MENTEN EQUATION.

Scatchard plot

[biomedical, chemical] Plot of specific binding bound ligands versus the ratio of specific binding (bound ligands) with respect to the concentration of free ligands; that is, “bound in correlation to free.” Introduced by GEORGE SCATCHARD (1892–1973) (also see MICHAELIS–MENTEN KINETICS [MICHAELIS–MENTEN EQUATION]) (see Figure S.19).

Figure S.19 Scatchard plot. (Courtesy of Stanford Medicine. http://mips.stanford.edu/courses/pharmacokinetics/Nonlin_comp/Rec_Lig_plex/2.html.)

Scatchard–Rosenthal plot

[biomedical] See **SCATCHARD PLOT**.

Scattering

[acoustics, astrophysics/astronomy, general, nuclear, optics] Redirection of the trajectory of **ENERGY** either lossless or lossy. The scattering mechanism is primarily based on diffuse discontinuities and nonuniformities in a medium of transport, which can be subatomic in size. The **MAGNITUDE** of interaction can be very locally diverse, rendering the observation an average over the selected size of the volume of interaction. The energy can be the representation of a **PARTICLE** moving with velocity v , or electromagnetic or acoustic energy. **COMPTON SCATTERING** describes the particle scattering during interaction with the **NUCLEUS**, where optical scattering involves the remittance of photons after resonant coupling with atomic and molecular constituents of a medium, such as tissue. The “**EQUATION OF RADIATIVE TRANSFER**” or “**Radiative Transfer Equation**” describes the **PROBABILITY** of redirection within a **SOLID ANGLE** for either galactic dust or biological media. Scattered **ACOUSTIC WAVES** are usually plagued by **DISPERSION** resulting from stress and strain in the medium, partially due to the acoustic density distortions themselves. The scattering phenomenon has a probability distribution which ties directly to a mean-free path-length. The mean-free path-length is an indication of the **DISTANCE** over which there are no anticipated interactions of both scattering or absorption. Optical scattering has been classified under two main formats: **RAYLEIGH SCATTERING** and Mie scattering, where the Rayleigh scattering pertains to small particle interaction and Mie scattering is more **MACROSCOPIC** (see [Figure S.20](#)).

Figure S.20 (a) The scattering concept exemplified and (b) pinball machine analogy how a photon is scattered by atoms in a turbid medium. (Note: A hole in the surface would represent absorption.)

Scattering cross section, Rayleigh

[general, optics] In case electromagnetic waves interact with particles that are smaller than the wavelength, the **LIGHT** is not necessarily absorbed, it will most likely be scattered. The **ELASTIC SCATTERING** of electromagnetic **RADIATION** on particles smaller than the wavelength is described by the work of the English mathematician **JOHN WILLIAM STRUTT LORD RAYLEIGH** (1842–1919). Lord Rayleigh made an effort to explain the appearance of the blue sky and red sunset in his work published in 1871. His approximations were based on the assumption that electromagnetic waves interacted with items smaller than the wavelength, the atomic dimensions of the gasses in the upper **ATMOSPHERE**.

Scattering length, singlet

[nuclear] In the NUCLEON scattering process the interaction of the ENERGY stream with the discontinuity or perturbation can be viewed for ELEMENTARY PARTICLES such as proton—proton two-body interaction is defined by the strength of the interaction, or the likelihood of the event to take place and at what energy transfer, defined by the scattering length. During the interaction of particles with simple SPIN configuration the SCATTERING process is strictly defined in a uniform energy approach. For atoms colliding with relative momentum $p = k\hbar$, the scattering length (a_{scat}) is related to the s -WAVE PHASE shift δ_0 defined as $a_{\text{scat}} = -\lim_{k \rightarrow 0} (\tan(\delta_0/k))$, where $k = 2\pi/\lambda$ is the wavenumber, λ the wavelength (deBroglie wavelength), and $\hbar = h/2\pi$; $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ PLANCK'S CONSTANT.

Scattering length, triplet

[nuclear] In the NUCLEON scattering process the interaction of the ENERGY stream with the discontinuity or perturbation can be viewed as nucleon—nucleon interaction that may take place with certain PROBABILITY, defined by the scattering length. During the interaction of nucleons with complex spin configuration the SCATTERING process needs to be defined with respect to the spins involved and the SPIN conversion probabilities. A nucleon with a spin TRIPLET STATE will have the probability for exchanging angular momentum in various formats and the energy configuration can be arranged in spin triplet channels. Each channel will be bound by a critical momentum for interaction. For resonant interaction this interaction length can be several hundred Bohr radii, yielding a high probability with significant exchange of energy, as a direct function of the interaction potential.

Scattering phase function

[astrophysics/astronomy, computational, optics] $p(\vec{s}, \vec{s}')$, is defined by the ANGLE (θ) between the direction of the rays incident on a sphere of medium ($\vec{s}$) with small but finite dimensions and the exiting, redirected rays with vector designation $\vec{s}'$: $\theta = \vec{s} \cdot \vec{s}'$. The PHASE function $p(\nu, \nu')$, is a function of the SCATTERING angle θ only, and can be expanded in a series of Legendre functions to the order n (which in fact represents the order of scattering events), where the following substitution has been made: $\nu = \cos \theta$; $p(\nu, \nu') = 4\pi \sum_0^\infty [1/(2n+1)] w_n p_n(\nu) p_n(\nu')$, where w_n is the scattering albedo, $w_0 = \mu_s/(\mu_a + \mu_s)$ the albedo of single scattering, with μ_s the scattering coefficient of the medium and μ_a the absorption coefficient (see Figure S.22).

Figure S.22 Scattering phase function. Scattering phase function of different ice crystals in comparison to water droplets at wavelength of 700 nm and a particle dimension of 95 μm . (Courtesy of André Ehrlich, University of Leipzig, Leipzig, Germany.)

Scattering phase function, Henyey-Greenstein

[astrophysics/astronomy, biomedical, computational, optics] The Henyey–Greenstein scattering phase function has been shown to be a good approximation of the true PHASE function of biological tissue and is given by $P_{\text{HG}} = (1/4\pi)[(1 - g^2)/(1 - 2g\mu^* + g^2)^{3/2}]$, where g is the mean cosine of the scattering ANGLE (anisotropy factor: $\langle \cos \theta \rangle$) and $\mu^* = \vec{s} \cdot \vec{s}' = \cos \theta$. A plot of the scattering phase function P_{HG} on a polar diagram represents the angular distribution of the scattering angle for an infinite medium and an infinite number of photons.

Schawlow, Arthur Leonard (1921–1999)

[optics, solid-state] Physicist from the United States. Arthur Schawlow was instrumental in the development of the predecessor to the LASER, the MASER (Microwave Amplification by Stimulated Emission of Radiation) introduced in 1954 in collaboration with CHARLES HARD TOWNES (1915–), for which they both received the Nobel Prize in Physics in 1964 (see [Figure S.23](#)).

Figure S.23 (a,b) Arthur Leonard Schawlow (1921–1999), photograph by Kenneth Sherwin and Frans Alkemade. (Courtesy of Stanford University, Stanford, CA.)

Scheele, Carl Wilhelm (1742–1786)

[chemical, optics] Researcher from Sweden, chemist and pharmacologist. The work by Scheele published in 1777, describes the discoloration of paper coated with silver chloride when exposed to sun-light. Forefather of PHOTOGRAPHY. Scheele was also credited for the discovery of oxygen (joint discovery) and documented barium, manganese, molybdenum and tungsten next to several other chemical compounds. His discovery

of chlorine, derived from pyrolusite, lead to a systematic disinfection of water. The use of chlorine, next to bleaching (discovered also by Scheele) offered a SOLUTION to the eradication of the spread of several disease through drinking water (see [Figure S.24](#)).

Figure S.24 Carl Wilhelm Scheele (1742–1786).

Scherrer, Paul (1890–1969)

[atomic, nuclear] Swiss physicist working in diffraction in the beginning of the twentieth century. Scherrer's work included the mathematical description of the correlation between the PARTICLE configuration (i.e., shape), captured by the shape factor (K_{shape}), spacing of the scattering matrix ($\tau_{\text{crystalline}}$) and the angular distribution of the scatter of X-RAY radiation (θ) or Bragg ANGLE. The correlation is captured by Scherrer as a function of wavelength: $\tau_{\text{crystalline}} = K\lambda/\beta \cos \theta$, where β is the line-broadening of the probing ray at full-width half-maximum (FWHM). Particularly in X-ray diffraction used in crystallography the SHAPE FACTOR plays a crucial role and is usually smaller than 0.9. The boundary conditions for the Scherrer equation are nanometer range ($<100 \text{ nm}$). The experimental verification was defined in the DEBYE-SCHERRER METHOD, which has led to naming the diffraction distribution the DEBYE–SCHERRER EQUATION on occasion (see [Figure S.25](#)).

Figure S.25 (a,b) Paul Scherrer (1890–1969). (a—Courtesy of ETH-Bibliothek Zurich, Switzerland; Bildarchiv: Com_XS129–02; b—Courtesy of Paul Scherrer Institute, Villigen, Switzerland.)

Schiff, Leonard Isaac (1915–1971)

[nuclear] Researcher from Germany involved with the photo-nuclear aspects of X-RAY imaging and specifically BREMSSTRAHLUNG. More specifically Schiff described the spectrum of X-ray diffraction PHOTON scattering (see [Figure S.26](#)).

Figure S.26 Leonard Isaac Schiff (1915–1971).

Schlieren imaging

[fluid dynamics, imaging] Described by AUGUST TOEPLER (1836–1912) in 1894. Method based on the DISPERSION of LIGHT resulting from density gradient and discontinuities. On transillumination of a medium optical density differences can be revealed based on BIREFRINGENCE that are indicative of temperature effects or composition by means of special filtering. The feature recognition aspects are based on the Cauchy theorem. The IMAGE formation is based on the angular deflection of a light ray when passing through a region characterized by boundaries between regions of different refractive index, as defined by Schell's law. The localized strain in the medium resulting from temperature effects or from deformation resulting from an applied torque can in this manner be revealed by Schlieren imaging and can be used for quality control and testing for integrity (see [Figure S.27](#)).

Figure S.27 (a) Schlieren imaging represented by the diffraction of light in the thermal convective flow above a heated object. (Courtesy of Andrew Davidhazy.) (b) Reflection "intensity" Schlieren for paraffin solution agitated by vibration.

Schlieren imaging for concentration

[biomedical, imaging, optics] Screening method for determination of molecular separation while applying the ULTRACENTRIFUGE principle. The general concept of LIGHT distortion resulting from density and associated index-of-refraction differences creates a diffraction pattern that illustrates the gradient in concentration of SOLUTE as a function of DISTANCE to the axis of rotation. The most obvious example of this is seen when adding sugar to water in a transparent beaker, showing the diffraction patterns (i.e., DISPERSION) in the SOLUTION as the solute migrates (see [Figure S.28](#)).

Figure S.28 Schlieren imaging for concentration, illustrating the dispersion in an inhomogeneous sugar solution.

Schmidt, Ernst Heinrich Wilhelm (1892–1975)

[fluid dynamics, general, thermodynamics] Engineer and physicist from Germany. Ernst Schmidt is best known for his contributions to the THERMODYNAMICS of flow as well as flow velocity profiling (see [Figure S.29](#)).

Figure S.29 Ernst Heinrich Wilhelm Schmidt (1892–1975). (Courtesy of Johanneum Lüneburg Informations system, Lüneburg, Germany.)

Schmidt number, ($Sc = \eta/\rho D_{AB}$)

[fluid dynamics] Dimensionless number defining the ratio of the momentum DIFFUSION to the molecular diffusion, where η is the viscosity, ρ the density and D_{AB} the diffusion coefficient for the constituents A and B . The number is named after the person who introduced the concept ERNST HEINRICH WILHELM SCHMIDT (1892–1975). The Schmidt number plays a role in identifying the EQUILIBRIUM STATE for OSMOTIC PRESSURE based on the transport of chemical species from the flow of BLOOD to the vascular (i.e., arterial/venous) WALL. For blood the Schmidt number is in the order $Sc \sim 10^5$.

Schottky, Walter Hermann (1886–1976)

[electronics, solid-state] German scientist who made several pivotal discoveries in solid-state ELECTRONICS and crystal structure. Schottky is also known for the invention of the screen-grid VACUUM tube. The screen-grid vacuum tube as introduced in 1915, is used to suppress the CATHODE ray emission flow of secondary electrons that are ejected from the ANODE on impact of the primary electrons and are hence a source of noise. Screen-grid vacuum tubes have a superior high frequency performance, with high gain. Walter Schottky is best known for the description of the solid-state ENERGY configuration that provided the tools for the development of the DIODE semiconductor. Of other theoretical description of the energy of a point-charge (with charge q) with respect to a flat metal surface: $E_{\text{charge}} = -q^2/16\pi\epsilon_{\text{EM}0}r$, where r represents the DISTANCE from the surface, and the permittivity of free space: $\epsilon_{\text{EM}0} = \epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{Nm}^2$ (see Figure S.30).

Figure S.30 Walter Hermann Schottky (1886–1976) in 1953. (Courtesy of Archiv der Max-Planck-Gesellschaft, Berlin-Dahlem, Germany.)

Schottky barrier

[electronics, solid-state] Metal-semiconductor ENERGY BARRIER for electron transport in a PN -JUNCTION configuration, often metal-silicon. The concept was introduced by WALTER HERMANN SCHOTTKY (1886–1976). The Schottky barrier may provide rectifying properties, converting alternating current in direct current, lending itself for the development of diodes. The Schottky barrier is defined based on the free-space SURFACE ENERGY when solving for a one-dimensional SCHRÖDINGER EQUATION for a single charged PARTICLE. The Schottky barrier representing the energy threshold that a charge needs to overcome to “conduct” through the barrier is defined as $E_{\text{Schottky}}(r) = b_{\text{Barrier}} - eEr - (q^2/4\pi\epsilon_r\epsilon_0r)$,

where $e = 1.60217657 \times 10^{-19}$ C is the electron charge (positive value), $E = V/d = F/q$ the applied electric field resulting from the externally applied POTENTIAL (V) spanning a DISTANCE d , b_{Barrier} the electric barrier height for the junction, often taken to be the work-function of the material (ϕ_{work}), the absolute permittivity of free space: $\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{Nm}^2$ and the RELATIVE PERMITTIVITY with respect to the material ϵ_r . The Schottky barrier fits in the Schrödinger equation as an operator as $(d^2/dr^2)\psi(r) = (2m/\hbar)E_{\text{Schottky}}(r)\psi(r)$, with m the particle mass, $\hbar = h/2\pi = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ PLANCK'S CONSTANT, and $\psi(r)$ the wave-function. The forward voltage for the Schottky barrier is in the range of 0.15–0.45 V (in comparison to the normal p-n silicon DIODE of 0.6–1.7 V). Schottky barriers have a very fast response time. The metals used in the junction are for instance tungsten, chromium, molybdenum and platinum.

Schottky diode

[electronics, solid-state] DIODE based on the junction between a METAL and a semiconductor, thus creating an asymmetric ENERGY configuration. In comparison, the first PN-JUNCTION was created in 1939 as a forerunner to semiconductor ELECTRONICS.

Schottky effect

[electronics, solid-state] The application of an external electric field to a METAL in VACUUM will increase the current density of the electrons being released from the metallic surface when administering heat. Raising the temperature of metals can result in the emission of electrons, THERMIONIC EMISSION. Even though the vacuum forms an INSULATOR, the ENERGY BARRIER for electron release can still be approximated by the SCHOTTKY BARRIER.

Schrieffer, Howard Lawrence (1948–)

[computational, general] Scientist from the United States with a special philosophy on force and ENERGY, called the GRAND UNIFIED THEORY, building on the work of Howard Mason Georgi III (1947–) and SHELDON LEE GLASHOW (1932–) published in 1974 (see [Figure S.31](#)).

Figure S.31 Howard Lawrence Schrieffer (1948–).

Schriefer Unified Theory

[computational, general] Also referred to as a Grand Unified Theories. Unification of all theories, introduced by HOWARD LAWRENCE SCHRIEFER (1948–). In principle, the unified theories provides the basis for the formation of planets, satellites, next to continents on earths. The UNIFIED THEORY describes the operation of pulsars and how they are formed. It also provides a common GROUND for WAVE and PARTICLE theory. Furthermore, the GRAND UNIFIED THEORY postulates that time and temperature are inappropriate characteristics to be used in scientific descriptions due to their convoluted properties, as are their antecedents. It also provides a unique description for gravitational interaction. The Grand Unified Theories are for all means and purposes consistent with the Lorentz Law, AMPÈRE'S LAW and electromagnetic gauge invariance. The concept of unified theory is based on the unification of several electromagnetic theories by JAMES CLERK MAXWELL (1831–1879). The concept is based on the fact that the strong, weak and ELECTROMAGNETIC THEORY of nuclear forces do not share the inverse square law that applies to GRAVITATION and the strict formulation of conservation of charges. The “unified” process makes an attempt to bridge the differences between electromagnetic theory and gravitational theory. The unified theories incorporate a broader range of symmetries, extending beyond the coordinate invariance principles of ALBERT EINSTEIN (1879–1955), incorporating the electromagnetic gauge invariance. In the unified theory the concept of “symmetry” loses significance after developing the gauge- and gravitational forces in a series beyond the second iteration, symmetry is lost/broken. The unified theory introduced by Schriefer (see GRAND UNIFIED THEORIES).

Schrödinger, Erwin Rudolf Josef Alexander (1887–1961)

[atomic, computational, energy, general, mechanics, nuclear, quantum] Physicist from Austria who, inspired by the principle of the DE BROGLIE WAVE, introduced the relativistic concept (determined by PROBABILITY rather than cause-and-effect) of wave-mechanics; the SCHRÖDINGER EQUATION OF MOTION, or SCHRÖDINGER WAVE EQUATION (see Figure S.32).

Figure 5.32 (Continued) Erwin Rudolf Josef Alexander Schrödinger (1887–1961) at the various Solvay conferences: (b) 1933 and (c) Erwin Schrödinger in 1933.

Schrödinger equation

[thermodynamics] See **SCHRÖDINGER EQUATION OF MOTION**.

Schrödinger equation of motion

[computational, nuclear, thermodynamics] Experiments performed in the early twentieth century gave rise to the notion that all particles in MOTION exhibit wavelike characteristics. The most formidable evidence came from the electron orbit model described by PRINCE LOUIS DE BROGLIE (1892–1987), requiring a standing WAVE to satisfy the filling of the various ORBITS. A PARTICLE moving in one dimension: x – direction, with mass: m , and with inherent kinetic ENERGY E and under a resident potential energy V , the SCHRÖDINGER WAVE EQUATION is defined as $(\partial^2 \Psi / \partial^2 x) + (8\pi^2 m / b^2)(E - V)\Psi = 0$, where $b = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$ PLANCK'S CONSTANT, and Ψ is the wave-function for the particle in motion describing the PROBABILITY distribution for have a specific configuration at a specific location. The SCHRÖDINGER EQUATION defines the kinetic energy combined with the potential (also known as the Hamiltonian: H operator) of the wave function Ψ , which encompasses all the dynamic statistics about a system. The function Ψ is a SCALAR function with complex values: $(E - V)\Psi = H\Psi = -(i\hbar/2\pi)(\partial\Psi/\partial t) = (-\hbar^2/8m)\nabla^2\Psi + V(0, x)\Psi$, where the Laplace operator represents the location derivative in second order: $\nabla^2 = (\partial^2/\partial x^2) + (\partial^2/\partial y^2) + (\partial^2/\partial z^2) = (\partial^2/\partial \theta^2) + (\partial^2/\partial r^2) + (\partial^2/\partial \phi^2)$. For the time-independent Schrödinger case, energy is derived using the operator $-i\hbar\partial/2\pi\partial t$, with the kinetic energy defined by the square of the momentum operator: $i\hbar\nabla^2/8m$. Using the boundary condition for the potential at $t = 0$: $V(0, x)$ and applying all the suitable boundary conditions, solving the Schrödinger differential equation generates a wave function Ψ which comprises all the characteristics and properties of the system. Alternatively, the Schrödinger equation can be expressed using the momentum of the particle, defined by $\hat{P}\Psi(r, t) = -(i\hbar/2\pi)\nabla^2\Psi(r, t)$, where the energy is linked to the momentum as $E = \hat{P}^2/2m$; where $\hat{P}$ defines the Momentum operator; $\hat{P} = m\vec{v}$, for a mass traveling with velocity $\vec{v}$. There is a remarkable similarity with the energetic format of the Hamiltonian equation, describing the total energy ($KE + U = E$, the sum of kinetic [$KE = (1/2)mv^2 = p^2/2m$] and potential [U] energy) as $(1/2m)p^2 + U = E$ described by WILLIAM HAMILTON (1805–1865). This concept was adapted by ERWIN

SCHRÖDINGER (1887–1961) into a differential equation; the wave equation. The EQUATIONS OF MOTION in Hamiltonian space are $\dot{p}_j = -(\partial H / \partial q_j)$ and $\dot{q}_j = +(\partial H / \partial p_j)$, with $H(p, q) = \sqrt{(m^2 + p^2)}$ the Hamiltonian function of energy for a particle. Also known as the Schrödinger Equation (see Figure S.33).

Figure S.33 Schrödinger motion.

Schrödinger Wave Equation

[computational, general, nuclear, thermodynamics] Mathematical description of the PROBABILITY of a phenomenon being at a certain place in a certain timeframe, expressed as $(1/2m)(i\hbar)^2 \{ (d^2\Psi/dx^2) + (d^2\Psi/dy^2) + (d^2\Psi/dz^2) \} + U\Psi = -E\Psi$, with E is the total ENERGY of the phenomenon, (x, y, z) three-dimensional CARTESIAN COORDINATES, Ψ the WAVE function of the phenomenon, U is the potential energy, m the mass of the object, $\hbar = h/2\pi$, where $h = 4.13567 \times 10^{-15}$ eVs the Planck constant, or referred to by MAX KARL ERNST LUDWIG PLANCK (1858–1947) as “the QUANTUM of action.”

Schrödinger's cat

[atomic, computational, energy, general, mechanics, nuclear, quantum] Paradox describing the fact that in quantum PHYSICS and WAVE MECHANICS all events are described in PROBABILITY of state. An event is not certain unless it is observed. The PARABOLA with the cat was introduced by ERWIN SCHRÖDINGER (1887–1961) in 1935. The interpretation of the Copenhagen description of QUANTUM MECHANICS left many questions in the interpretation of how reality and probability are not compatible in quantum physics. The cat anecdote describes how one event may control the outcome of another event without a definite cause and effect. The cat is supposedly locked in a box that contains a mechanism controlled by a nuclear disintegration. The mechanism is initiated by the DECAY of a RADIOACTIVE ISOTOPE such as uranium that will result in the registration by a GEIGER COUNTER which in turn engages a hammer that shatters a GLASS jar containing the poisonous hydrocyanic ACID. In case the uranium decays the cat will be dead after inspection of the cage when 1 h has lapsed, in case the ISOTOPE did not decay the cat will be alive. In QUANTUM mechanical terms the cat is bot

alive and dead at the same time, whereas in classical terms the cat will be either alive or dead based on a more predictable cause–effect relationship, such as being confined with a mouse for 1 h (see [Figure S.34](#)).

Figure S.34 Concept of probability explained by Schrödinger's cat; which decay event will make the hammer strike the glass jar which will release the poisonous gas, there will be a probability associated with this occurrence.

Schuster, Arthur, Sir (1851–1934)

[astrophysics/astronomy, computational, optics] German physicist who provided critical steps in the development of a computational mechanism to describe the diffuse propagation of LIGHT through turbid media. Schuster worked on X-RAY imaging and OPTICS as well as SPECTROSCOPY. The works of KARL SCHWARZSCHILD (1873–1916) and SUBRAHMANYAN CHANDRASEKHAR (1910–1995) were inspired by his efforts on the mathematical description of the propagation of light through an attenuating and scattering medium. The culmination of Dr. Schuster's work on optics is found in the EQUATION OF RADIATIVE TRANSFER, pertaining to both astronomy and BIOMEDICAL OPTICS. Schuster also provided elementary contributions to the discovery of the electron. In this work he provided a mechanism to derive the ratio of charge to mass for CATHODE RAYS, discriminating protons from electrons, later formalized by ERNEST RUTHERFORD (1871–1937) (see [Figure S.35](#)).

Figure S.35 Sir Arthur Schuster (1851–1934) in 1912, by William Orpen.

Schwarzschild, Karl (1873–1916)

[astronomy, biomedical, computational, general, optics] Astrophysicist and mathematician from the Prussian Empire (Germany). Karl Schwarzschild worked parallel with SIR FRANZ ARTHUR FRIEDRICH SCHUSTER (1851–1934) on the theoretical description of RADIATIVE TRANSFER with respect to the RADIATION emitted from stars traversing a UNIVERSE filled with dust, gasses and planets, published in 1905 and 1906, respectively. Karl Schwarzschild used photographic recordings for QUANTIFICATION of the brightness of stars and deriving the optical path for reaching EARTH. The HEAT TRANSFER and emission of radiation from stars and the interaction with cosmic material forms the basis of BIOMEDICAL OPTICS in the EQUATION OF RADIATIVE TRANSFER, also found as Radiative Transfer Equation (*also see* BIOMEDICAL OPTICS) (see [Figure S.36](#)).

Figure S.36 Karl Schwarzschild (1873–1916).

Scuba gear

[biomedical, fluid dynamics] Apparatus used for deep-sea diving that will provide an oxygen supply under controlled circumstances. The equipment concept was described by the French author Jules Verne (1828–1905) in “Vingt Mille Lieues sous les mers,” 1870 (*Twenty Thousand Leagues Under the Sea*). The Jules Verne concept was based on the explorations by earlier engineers and inventors such as the British engineer, John Smeaton, who invented the AIR pump in 1771. Another self-sustaining breathing device was constructed in 1825 by the English inventor William James using a copper helmet attached to a vessel (belt) filled with compressed air. Another Englishman, Henry Fleuss, conceived a recirculation device infusing pure Oxygen into the respiratory system in 1876, which made him fall victim to the fact that pure Oxygen deregulates the human breathing mechanism. The inhalation of the pure oxygen killed him as a result of the biofeedback deregulation. The human RESPIRATION is regulated by chemical sensors that respond to dissolved Carbon Dioxide; the reaction of WATER (H_2O) with CO_2 forms H_2CO_3 (carbonic ACID), which has an inherent acidity. The lack of CO_2 makes the autonomic nervous system shut down the desire to inhale fresh air. In 1873 an entirely new approach resulted from the work of Benoît Rouquayrol and Auguste Denayrouze resulting in a rigid diving suit with a regular air supply. The concept was made of METAL and weighed approximately 100 kg. Further improvements resulted from the efforts by engineer and sensationalist Harry Houdini in the year 1921 (born Ehrich Weiss 1874–1926 in Budapest, Hungary). The first metallic caissons used for underwater exploration were cumbersome and did not allow free movement. These constructions used an air-hose that lead to the surface of the water requiring manual labor to PUMP fresh air to the diver. In 1943 the French naval officer Jacques-Yves Cousteau (1910–1997) and his fellow inventor and engineer Émile Gagnan (1900–1979) made a breakthrough contribution to the work of several predecessors and contemporaries in the introduction of the compressed air breathing devices for

extended underwater exploration: the “Aqualung.” Jacques Cousteau is mostly known for his oceanographic explorations, documentaries and nature conservation efforts pertaining to the marine flora and fauna (see Figure S.37).

Figure S.37 (a) Diver in scuba gear and (b) Jacques-Yves Cousteau (1910–1997). (Courtesy of the Cousteau Society, Paris, France.)

Second

[general] Measurement of time; Definition: SI: based on the earth’s revolution in 24 h, originally introduced as the fraction of the average length of a day as $1/60 * 1/60 * 1/24 * \text{mean duration of a day averaged over a year}$. The current definition of the second is the duration of 9,192,631,770 oscillations of the Cesium-133 ATOM between the lowest two ENERGY states, accurate to 1 in 10^{13} . This standard is referred to as the “ATOMIC CLOCK,” introduced in 1967 (see Figure S.38).

Figure S.38 The second on an analog time keeping piece.

Second law

[thermodynamics] See SECOND LAW OF THERMODYNAMICS.

Second law, Kelvin–Planck’s statement

[thermodynamics] “It is unachievable to build a fully functional ENGINE that is solely based on the extraction of heat from a reservoir at a single temperature while converting all the acquired heat perfectly into MECHANICAL ENERGY.” Introduced by LORD KELVIN (1824–1907).

Second law of Faraday

[Atomic, general, nuclear, quantum, thermodynamics] “The total mass of SOLUTE liberated from a SOLUTION is proportional to the total quantity of charge traversing through a circuit that has the solution as the integral part of the sole current loop” (see FARADAY, SECOND LAW OF).

Second law of thermodynamics

[general] “It is unachievable to build a fully functional ENGINE that is solely based on the extraction of heat from a reservoir at a single temperature while converting all the acquired heat perfectly into MECHANICAL ENERGY.” The change in ENTROPY (S) of all systems involved in a process will always be positive: $\Delta S \geq 0$, noting that for an ideal (theoretical case) reversible process the entropy will remain unchanged (see THERMODYNAMICS, SECOND LAW OF).

Second law of thermodynamics, Carathéodory’s statement of the

[computational, thermodynamics] Axiomatic expression by the Greek mathematician CONSTANTINE CARATHÉODORY (1873–1950) with respect to the subsystems with equal or less parameters and equal or less data-points/coordinates expressed in 1910 pertaining to the SECOND LAW OF THERMODYNAMICS, centered around PFAFFIAN differential equations eliminating the need for imaginary engines to compensate for deviations resulting from the improbability of the “perpetuum mobile,” based on geometric formulation. The basis of the Carathéodory’s theorem is the fact that “In the proximity of any EQUILIBRIUM STATE of a system (composed of any number of thermodynamic coordinates, and valid in any geometric configurations), there will be states that cannot be achieved through reversible adiabatic processes.”

Second law of thermodynamics, Clausius formulation

[general, thermodynamics] Expression of the lack of 100% efficiency in ENERGY conversion, similar to the SECOND LAW, KELVIN–PLANCK’S STATEMENT. RUDOLF JULIUS EMANUEL CLAUSIUS (1822–1888) formulated that a refrigeration system cannot transfer heat from the cold to the hot reservoir without the use of an external source and hence requires external energy.

Second order differential equations

[computational] Differential equations that include derivatives up to the second order, generally either time or location specific.

S

Second order phase transition

[computational, thermodynamics] At the critical point, where the critical temperature and critical pressure are reached, the PHASE TRANSITION between LIQUID and VAPOR anomalous behavior is observed in the thermodynamic parameters such as SPECIFIC HEAT and compressibility due to the fact that the density of the liquid and vapor phase at the raised temperature and pressure has reached equilibrium, they are

identical. At the critical point the correlation length associated with the physical phenomena has exceeded the standard length (e.g., intermolecular DISTANCE) for the normal phase transition (see Figure S.39).

Figure S.39 (a,b) Diagram outlining the configuration of a second-order phase transition.

Second-generation of matter

[atom, high-energy, nuclear, solid-state] ELEMENTARY PARTICLES discovered in a certain order, as outlined under Quarks. Quarks (CHARM, strangeness); Leptons (MUON, μ -neutrino).

Sediment equilibrium

[biomedical, chemical, mechanics] Mechanism of action used to determine molecular weight of the SOLUTE under ULTRACENTRIFUGE treatment. At the point of equilibrium between DIFFUSION and sedimentation the concentration $[C]$ will depend on the DISTANCE (r) to the axis of rotation: $[C_r]$ as a function of ANGULAR VELOCITY ω . The MOLECULAR WEIGHT (M) distribution under ABSOLUTE TEMPERATURE (T) and rotational angular velocity: ω , with the assigned partial specific volume of the solute $\bar{V}$ expressed as $M(r) = RT \ln([C_r]/[C_n]) / [(1 - \rho \bar{V}) \omega^2 (r_2^2 - r_1^2)]$, where R is the UNIVERSAL GAS CONSTANT, and ρ is the SOLVENT density based on the dissolved constituent. Under conditions of very large molecular weight (i.e., MACROMOLECULES) the sedimentation time duration will reach equilibrium after an extensive period of slow rotational centrifuge revolution, and can take in excess of 24 h in certain cases.

Sediment equilibrium in a density gradient

[biomedical, chemical, mechanics] Mechanism of action used to determine molecular weight of a binary solutions under ULTRACENTRIFUGE treatment. Solutions where the SOLUTE with low MOLECULAR WEIGHT (M) has a close to equivalent weight to the SOLVENT it will tend to segregate as a function of DISTANCE to the rotational axis (r), which can be quantified when equilibrium is established. Due to the equivalence the solute will be buoyant and segregation will depend on the density gradient in the medium: $d\rho/dr$, where ρ is the solvent density based on the dissolved constituent, with a band-width per concentration that is identified by the one-dimensional standard deviation σ . The molecular weight (M) distribution under ABSOLUTE TEMPERATURE (T) and rotational ANGULAR VELOCITY: ω , with the assigned partial specific volume of the solute $\bar{V}$ expressed as $M = RT / [\bar{V} \omega^2 (d\rho/dr) \sigma^2 r]$, where R is the UNIVERSAL GAS CONSTANT.

Sedimentation velocity

[biomedical, chemical, mechanics] Used in the process describing the rate of change expressed by the sedimentation coefficient: $\zeta = (dr/dt)/\omega^2 r$, with ρ the SOLVENT density based on the dissolved constituent, the DISTANCE to the axis of rotation r and rotational ANGULAR VELOCITY ω , and dr/dt the SOLUTE sedimentation velocity. This mechanism of action is used to determine molecular weight of the solute under ULTRA-CENTRIFUGE treatment. The MOLECULAR WEIGHT M of the solute follows from $M = RT\zeta/(1 - \bar{V}\rho)$, where R is the UNIVERSAL GAS CONSTANT, ρ is the solvent density and D is the DIFFUSION coefficient.

Seebeck, Thomas Johann (1770–1831)

[energy, thermodynamics] Scientist from the Prussian Empire/Estonia (Russia?). Thomas Seebeck discovered in 1821 that a compass needle would be deflected by a closed loop formed by two different metals joined in two places, with a temperature difference between the junctions. Additional work by Thomas Seebeck is in the precursor to the discovery of PHOTOGRAPHY. Seebeck described the change in appearance of silver-chloride under the influence of LIGHT in 1810 (see LOUIS-JACQUES-MANDÉ DAGUERRE [1771–1851]) (see Figure S.40).

Figure S.40 Thomas Johann Seebeck (1770–1831). (Courtesy of Hans Wahl, Anton Kippenberg: Goethe und seine Welt, Insel-Verlag, Leipzig 1932 S.204.)

S

Seebeck effect

[electromagnetism, thermodynamics] The conversion of temperature differences directly into ELECTRICITY. The voltage (electromotive force: EMF: V_{EMF}) produced between two junctions is proportional to the temperature difference between those two point: $V_{\text{EMF}} = S_{\text{Seebeck}} (T_{\text{high}} - T_{\text{low}})$, where the coefficient S_{Seebeck} represents the influence between the two media in contact on the voltage difference, which relates to the PELTIER COEFFICIENT (Π_i) as $TS_{\text{Seebeck}} = \Pi_i$. The EMF produces a current which can be registered by a GALVANOMETER. This effect was described in 1826 by THOMAS SEEBECK (1770–1831) (also see PELTIER EFFECT).

Segrè, Emilio Gino (1905–1989)

[nuclear] Physicist from Italy. Segrè received the Nobel Prize in Physics in 1959 for his contributions and discoveries in PARTICLE physics, including the discovery of the ELEMENTS technetium and astatine, as well as his work on the antiproton (subatomic antiparticle) with Owen Chamberlain (1920–2006) and Clyde Wiegand (1915–1996) in 1955 (see Figure S.41).

Figure S.41 Emilio Gino Segrè (1905–1989).

Seismic

[acoustics, general, geophysics, mechanics] Physical phenomena associated with shallow earthquakes causing surface faulting (i.e., instability or mode of **VIBRATION**) or the damped oscillatory **GROUND** movements with destructive effects resulting from a major **EARTHQUAKE**. Seismic models rely on finite **ELEMENT** reconstructive structural and stratigraphic representation. Here stratigraphy pertains to the study of the composition, relative ages with associated historical value, as well as the distribution of layers of sedimentary rock (i.e., strata), combined with the interpretation of strata to uncover the Earth's geological history (see [Figure S.42](#)).

Figure S.42 Graphical representation of the seismic concept.

Seismic acoustic imaging

[acoustics] Large-scale imaging of predominantly geological and aquatic features by means of artificially induced seismic ACTIVITY, for example, explosions or impact collisions (either using a heavy weight or compressed AIR). The induced pressure wave resulting from the impulse source, acts as an imaging source. Using the obtained FREQUENCY SPECTRUM assumptions can be made about the elastic modulus distribution of the volume under interrogation, which can be used to define the WAVE-EQUATION responses and hence use time-of-flight of echoes for imaging purposes, including compensations for SCATTERING resulting from inhomogeneities and discontinuities. This type of imaging is used in the localization of water sources or OIL pockets (e.g., SEISMIC prospecting) (see [Figure S.43](#)).

Figure S.43 Seismic imaging diagram, based on S-wave and P-wave; Cross section of Earth with different seismic paths with reflection and refraction on the layers. Mechanism using two or more locations where seismic activity is recorded to triangulate the source of the seismic activity, which could be man-made such as underground nuclear explosions.

Seismic wave

[acoustics, general, geophysics, mechanics] Deformation WAVE resulting from natural forces such as volcanic eruptions, METEOR impacts, tsunamis, earthquakes, next to man-made impulse forces such as explosions. Underground nuclear tests are easily identified at great DISTANCE based on seismic wave propagation, specifically using triangulation from several detection bases (see [Figure S.44](#)).

Figure S.44 Diagram of Seismic wave propagation.

Seismic wave, dissipative effects

[acoustics, geophysics, mechanics] The propagation of seismic waves resulting from earthquakes and other natural (e.g., volcanic eruptions) and man-made phenomena (e.g., explosions, fracking) is a perturbation that is subject to a broad frequency spectrum, and additionally the attenuation parameters with respect to the damped waves are a function of the frequency and local geological material configuration (e.g., visco-elastic behavior). The attenuation is generally described by an elastic—ENERGY dissipation factor defined by the concept “ q ,” where $q = \Delta E / 2\pi E_{\max}$, where $E_{\max}$ represents the maximum energy contained in the SEISMIC event and ΔE is the loss of INTERNAL ENERGY during one cycle of the mechanical/acoustic perturbation. The full range of frequencies associated with mechanical oscillations of the EARTH’S CRUST can be described by extending from 0.0005 Hz (period greater than 2000 s, ~35 min) to approximately 100 Hz (period 0.01 s). The other identifier related to the seismic dissipative effects is the QUALITY FACTOR: $Q \equiv 1/q$. The attenuation as a function of FREQUENCY ($\nu = \omega/2\pi$; ω the ANGULAR FREQUENCY) can generally approximated by a POWER LAW, providing the equivalence: $q \propto \omega^{-\alpha_{\text{acc}}}$, where generally $\alpha_{\text{acc}} < 0.5$ is the model factor for the phenomenon. This indicates that higher mechanical displacement frequencies will DECAY faster than low frequency patterns. The anelastic and elastic properties of the earth’s crust are a function of the local geological formations and configurations. Geological pattern may be rock formations, clay and water; all of which may be function of depth. These differences in related and associated Young’s Moduli will result in dispersive effects. The frequency dependency is further complicated by the fact that the seismic waves can be composed of spheroidal modes (large scale) expressed in propagating SURFACE WAVES, or normal mode standing waves. When these modes reach discontinuities at an ANGLE the WAVE will refract, similar to optical electromagnetic waves. The FREQUENCY SPECTRUM of the attenuation can be represented in “frequency modes,” or “angular (frequency) modes” (angular modes is the preferred term). The attenuation as a function of angular mode can be written with local radial shear and bulk moduli: $\mu_{\text{shear},0}$ respectively $K_{\text{bulk},0}$; next to the radial attenuation for shear, respectively bulk: $q_{\mu,\text{shear},0}$ respectively $q_{K,\text{bulk},0}$: $q = \int_0^R (\kappa_0 q_{K,\text{bulk},0} K_{\kappa} + \mu_{\text{shear},0} q_{\mu,\text{shear},0} K_{\mu_{\text{shear}}}) dr$, where R is the earth’s radius and K_{κ} respectively $K_{\mu_{\text{shear}}}$ are the bulk and shear kernels, the mathematical vector ELEMENTS that provide an indication of discontinuity or deviation from a “smooth” pattern. For long period seismic waves, greater than 300 s, the model factor decreases and eventually becomes negative. The DISPERSION between waves with different frequencies can be captured by the wave propagation velocity (ν_{ω_i}) in the form: $\nu_{\omega_2} / \nu_{\omega_1} = 1 + (q/\pi) \ln(\omega_2/\omega_1)$ in case the model factor is zero ($\alpha_{\text{acc}} = 0$), which describes phenomena occurring in the lower mantle. For the upper mantle the model factor is generally nonzero and the dispersion becomes: $\nu_{\omega_2} / \nu_{\omega_1} = 1 + [q(\omega_1)/2] \cot(\alpha_{\text{acc}}\pi/2) [1 - (\omega_2/\omega_1)^{\alpha_{\text{acc}}}]$.

Seismology

[energy, fluid dynamics, general, geophysics, mechanics] Field of PHYSICS dealing with physical phenomena in the solid part of the PLANET considered to be behaving as a LIQUID. The process of earthquakes and WAVE propagation (e.g., SEISMIC WAVES) falls under seismology. Additionally the sonic probing of the planets crust is also part of seismology, in this case small explosions generate a sonic (i.e., acoustic) wave that can be used to IMAGE the structural composition of the solid surface layer of the planet in a manner similar to ULTRASONIC IMAGING in biology and MEDICINE. The formation and propagation of TSUNAMI waves in water beds also falls under seismology.

Seismometer

[acoustics, general, geophysics, mechanics] Device used to register oscillations in the EARTH'S CRUST. Specific applications are in earthquakes, using the Richter scale as an indicator of MAGNITUDE on a logarithmic basis (see [Figure S.45](#)).

Figure S.45 (a,b) Seismometer.

Selectin

[biomedical, chemical] Molecular chains that provide the ADHESION of the surface of the membrane of leukocytes (their host environment) and endothelial cells that have been activated for construction in vascular assembly and healing. The main binding attraction of the selectin (glycol-) protein is to carbohydrates. Selectins form a specific class in biology providing cell-to-cell interaction. This interaction can be divided in four types of receptors: CADHERINS, selectins, INTEGRINS and IMMUNOGLOBULIN SUPERFAMILY (*see* CADHERINS).

Selection rule and

[atomic, computational, nuclear, quantum] (*see also* angular momentum conservation, parity conservation) Quantum-mechanical rules setting the stage for ENERGY balance pertaining to CONSERVATION OF ANGULAR MOMENTUM and conservation of PARITY in electron orbital configuration. The selection rules form the guide-book to electron transitions, as well as the PROBABILITY of each potential transition. The notation and rules are slightly different between atomic transitions and those for molecular excitation and DECAY. Two phenomena stand out in the electron transition: the PASCHEN BACK EFFECT and the ZEEMAN EFFECT. The Zeeman effect is generally determined by the selection rules, with specific selection rules applied to the NORMAL ZEEMAN EFFECT and the ANOMALOUS ZEEMAN EFFECT. Most orbital transitions are forbidden by selection rules. The standing order of selection rules are as follows. The value of the magnetic moment QUANTUM NUMBER ℓ changes in unity: $\Delta\ell = \pm 1$ and the MAGNETIC moment remains unchanged or changes by unity: $\Delta m = 0, \pm 1$. For the normal Zeeman effect: $\Delta L = 0, \pm 1$, however there is no ALLOWED TRANSITION that involves $L = 0$ to $L = 0$; $\Delta M_L = 0, \pm 1$; $\Delta S = 0$; and $\Delta M_S = 0$, where L represents the angular momentum of the ORBITAL ANGULAR MOMENTUM of the electron, S represents the ELECTRON SPIN (which cannot change, since that would mean a reversal of rotation direction), J represents the TOTAL ANGULAR MOMENTUM quantum number (a transition that involves $J = 0$ to $J = 0$ is also not allowed), respectively M_L the magnetic moment and M_S the SPIN moment, and in reference n is the primary quantum number. Some of the rules find their origin in the RUSSELL–SAUNDERS APPROXIMATION OF ELECTRON COUPLING.

Selectively permeable

[biomedical] The restrictive transport of molecules and particles through the membrane of CELL based on charge polarity and/or shape and size (more specifically pertaining to MOLECULAR WEIGHT or macroscopically to the chemical “nanoparticle”).

Self-avoiding walk

[computational] In computational methods the SOLUTION is derived for a process involving each point in the process only once, meaning that the path in n -dimensional space never intersects in the steps in the mathematical algorithm. This process resembles a very tightly organized maze or LATTICE. The process is used in simulation techniques, more prevalent in for-instance Monte-Carlo simulations and Java programming. Expressed in matrix format this would entail a one-sided matrix, specifically if the matrix would be symmetric. For an $n \times m$ matrix the computational process can migrate from one diagonal to the other diagonal. When numerically moving in the positive direction there will be a total of $(n + m/n, m)$ different potential paths available (see Figure S.46).

Figure S.46 Diagram illustrating the concept of Self-avoiding walk.

Self-consistent field

[atomic, computational] Method used to calculate the three-dimensional potential distribution for an electron cloud also referred to as the Hartree–Fock method.

Self-energy, coulomb

[nuclear] In the computation of the Coulomb ENERGY (E_{Coulomb}) with respect to the electron potentials ($V(\vec{r})$) of an electron (e) distribution with charge density ($\rho(\vec{r})$) over space ($\vec{r}$) the total Coulomb energy representing the total energy between the protons of the NUCLEUS is given by $E_{\text{Coulomb}} = (1/2)e \int_0^\infty \rho(\vec{r}) V(\vec{r}) 4\pi r^2 dr = 1/8\pi \int_0^\infty (\epsilon(\vec{r}))^2 4\pi r^2 dr$, where $\epsilon(\vec{r})$ is the local electric field. The SOLUTION is proportional to r^4 inside the nucleus and r^{-2} outside. The self-energy is the Coulomb energy of a single isolated PROTON with its WAVE-function spread-out over the entire volume of the nucleus.

Self-excited vibration

[computational, dynamics, fluid dynamics, general, mechanics] In contrast to forced vibrations the driving mechanism comes from within the system, maintaining the MOTION with INTERNAL ENERGY. The OSCILLATION frequency is thus not linked to a driving oscillation frequency. The phenomenon is described by the EQUATION OF MOTION ($m(d^2x/dt^2) + c(dx/dt) + kx = 0$, where m is the mass of the oscillating object, x the displacement, k the spring constant, $d^2x/dt^2 = a$ the acceleration, and $c = \text{const}$ representing the

predictable pattern of temporal changes in boundary conditions, including density, for instance COMPLIANCE) as a homogeneous SOLUTION that however is unstable. Examples of self-excited vibration are the hysteretic whirl, and pulsatile longitudinal loading. Another example is found in the FLUID motion of an enclosed rotor or rotor-axis.

Self-induced electromotive force

[general] The response in induced electro-motive-force voltage resulting from a change in a CURRENT (I) in a circuit that has a coil as a component as defined by LENZ'S LAW. The induced rate of change in the MAGNETIC FIELD resulting from the change in current inflicts its own emf. The self-induced EMF will be opposite the naturally occurring EMF resulting from external sources: $\varepsilon_{\text{EMF}} = -L_{\text{ind}}(dI/dt)$, where L_{ind} is the coefficient of self-inductance, a proportionality factor.

Self-inductance (L_{ind})

[electromagnetism, general] Proportionality that indicates the readiness of the MAGNETIC FLUX (Φ_m) to follow the change in current (I): $N_{\text{coil}}\Phi_m = L_{\text{ind}}I$, where N_{coil} represents the loops of the coil.

Semiconductors

[atomic, general, nuclear] Material made of ELEMENTS with specific ELECTRON configuration, for instance crystalline structures consisting of, but not limited to Galena, Silicon, Gallium or Germanium. An ATOM has the electrons arranged according to the BOHR ATOMIC MODEL with electrons in specific allowed ENERGY LEVELS or ORBIT SHELLS. In comparison with either INSULATOR or CONDUCTOR the electron configuration falls between these two. In an insulator the CONDUCTION BAND containing FREE ELECTRONS is unpopulated and separated by a forbidden gap from the VALENCE BAND, whereas in conductor configuration the valence band is overlapping the conduction band, hence populating the conduction mechanism of action with free electrons. In electron device fabrication the concept of DOPING refers to the introduction of foreign atoms into the LATTICE structure or random atomic structure of the semiconductor decreasing the gap between the conduction band and the valence band, hence lowering the ENERGY requirements to initiate conduction. Two kinds of doping can be used: *N-TYPE* referring to the introduction of an atom with an excess odd number of valence electrons (for instance, arsenic with five valence electrons) which can be transferred to the conduction band of the semiconductor atoms. The other doping is *P-TYPE*, referring to a deficiency in electrons (i.e., hole) in the valence band, such as three valence electrons in GALLIUM, which will retrieve loosely bound electrons for instance from the semiconductor Silicon. Both *n*-type and *p*-type doped semiconductors create an adjustable conductor, which can be turned into a conductor by an externally applied electric field. In electronic device design *p*-type and *n*-type materials are matched in various combinations: *pn*-JUNCTION, and sandwich structures: pnp, and npn and the like. In the energetic configuration the *p* and *n* structure are separated by a DEPLETION LAYER that forms a transition between the energy levels in the respective media. These combinations can create a DIODE or TRANSISTOR respectively and more complex INTEGRATED CIRCUITS.

Semipermeable membrane

[biomedical, chemical, thermodynamics] Membrane that will permit selective transportation of ions and molecules based on charge and size respectively or combined (see [Figure S.47](#)).

Figure S.47 Semipermeable membrane.

Separation boundary layer

[fluid dynamics] In fluid flow the LAMINAR FLOW may be disturbed by surface features with respect to the flow lumen that cause TURBULENCE that can be confined to a layer that is attached to the surface starting at the “point of separation” at the WALL. The flow outside the separation layer will maintain the original laminar profile and can be initiated at an abrupt change in radius or localized attachments, such as rust or plaque (biological vascular atherosclerosis).

Separation of variables

[computational, nuclear] Mathematical method for solving convoluted expressions, that use more than one dependent variable by separating the dependent variables out as independent variables. In spherical coordinates this yields: $\Psi(r, \theta, \phi) = R(r)\Theta(\theta)\Phi(\phi)$, giving three functions that can be solved independently, in this case with respect to radius (r), azimuth ANGLE (θ) and ZENITH ANGLE (ϕ).

Sextant

[computational, general, geophysics] Instrument used by sailors in the late seventeenth and most of the eighteenth century for navigation at sea. The sextant can determine the ANGLE between two points in a distant field, such as celestial objects and when the location of one of the objects is known as a function of time, the other object can provide the mechanism for determining the orientation as well as latitude and longitude of the location from which the MEASUREMENT is made. The device uses two mirrors that can be used to merge (superposition) the images of two objects by adjusting the angle of the second MIRROR, yielding the angle of the second object (e.g., the SUN) with respect to the first (i.e., the horizon).

The accuracy of the sextant is 10 s, where a degree is subdivided in 60 minutes and a minute in angle is subdivided in 60 s (see [Figure S.48](#)).

Figure S.48 Sextant.

Shadowgraph method

[acoustics, fluid dynamics, optics] Imaging method that uses the optical BIREFRINGENCE in a medium to indicate temporal and spatial gradients and discontinuities. The imaging mechanism relies primarily on transmission of LIGHT, and is used to highlight TURBULENCE and Mach-lines in fluid-flow with respect to steady-state or moving objects. Acoustic WAVE propagation can this way by illustrated due to the density gradient for the trough and crest regions (*also see* SCHLIEREN IMAGING) (see [Figure S.49](#)).

Figure S.49 Shadowgraph from a flying bullet, using the birefringence of the Mach-line edge of the wave-front.

Shaft horsepower

[fluid dynamics] The power produced by the shaft of a PUMP, or PROPELLER after the transferal by a gear system from the ENGINE classified by engine horsepower (the power output of the engine itself). Even though horsepower is not a standard unit it is still used in general descriptive specification, such as for a car, boat or compressor. The conversion from HORSEPOWER (*hp*) to the SI unit Watt is: $1 \text{ hp} = 0.745699872 \text{ kW}$. Also referenced as break-horsepower.

Shallow-water tides

[fluid dynamics] Tidal movement in shallow seas and estuaries. The movement of water in shallow seas is hardly affected by the gravitational influences from the SUN and MOON as in the deep water TIDAL MOTION described by PIERRE-SIMON DE LAPLACE (1749–1827) in 1775 when he developed the dynamic theory of tides, in follow-up on the work by DANIEL BERNOULLI (1700–1782) in 1740. In shallow seas and estuaries the tides are a fluid-dynamic response to the deep-water tides based on restrictive flow due to a gradient in water level at the inflow and outflow point(s) with respect to deep sea tidal motion. Tides are WAVE that conform to special formulations of the WAVE-EQUATION, where the solar influence is strictly periodic (semidiurnal; twice daily), however the Moon will provide a modulation effect. Water is considered shallow when the depth is less than one twenty-fifth of the perceived tidal wavelength. Normal SURFACE WAVES can be represented by a PARTICLE at the surface moving in a circular pattern, however for shallow alter this motion becomes elliptical (see [Figure S.50](#)).

Figure S.50 Shallow water tides in Cornwall England, Polperro harbour.

Shannon, Claude Elwood (1916–2001)

[computational, electronics, imaging, theoretical] Mathematician and electronic engineer from the United States. Claude Shannon is best known for his SAMPLING theorem, also known as the Shannon–Nyquist

theorem, or plain Nyquist theorem. Claude Shannon may be considered as one of the initial explorers into the concept of information theory. Shannon was also a cryptographer (*also see* **HARRY NYQUIST** [1889–1976]) (see [Figure S.51](#)).

Figure S.51 Claude Elwood Shannon (1916–2001). (Courtesy of Bell Labs, Murray Hill, NJ, USA.)

Shannon entropy (H_S)

[imaging, theoretical] Measure of randomness and uncertainty in a parameter (χ) observed in a state-space coordinate system (Ω), expressed as $H_S(\chi) = -\int_{\Omega} p(\chi) \log p(\chi) d\chi$, where $p(\chi)$ defines the PROBABILITY density function of the variable χ . The Shannon entropy is used in IMAGE processing, specifically with respect to image registration. Also referred to as DIFFERENTIAL ENTROPY.

Shannon sampling law

[computational, thermodynamics] See **NYQUIST–SHANNON SAMPLING THEOREM**.

Shannon sampling theorem

[computational, thermodynamics] See **NYQUIST–SHANNON SAMPLING THEOREM**.

Shape factor

[atomic, imaging, nuclear] Descriptive form without specific defining magnitudes that relate to a specific functional purpose. Frequently represented by DIMENSIONLESS NUMBERS. In SIGNAL processing the shape-factor of a band-pass filter provides a spectral format, while in X-RAY crystallography the shape factor describes the correlation between the X-ray diffraction pattern and the crystallite structures; in fluid-dynamics this defines the BOUNDARY LAYER geography. In IMAGE analysis the shape factor determines the “compactness” of a shape. One example is the ratio of the area of a random shape to the comparative area of a circle which has the same perimeter, since the circle is the most compact shape, known as the isoperimetric quotient.

Shape memory alloys (SMAs)

[biomedical, mechanics] Memory material that will return to a preset shape (“memory”) when exposed to a predetermined temperature. The most used alloys is Nickel–titanium, known as NITINOL (known for the origin in 1961 Nickel Titanium Naval Ordnance Laboratory), additional alloys with shape retention are

copper–aluminum–nickel, copper–zinc–aluminum, and a variety of iron–manganese–silicon alloys. The memory effect can be explained by a crystal structure on an atomic level with an associated low equilibrium ENERGY which is accessed through a set of PHASE changes, known respectively as martensite and austenite, where the austenite phase is the “memory shape phase” of the configured alloy (see Figure S.52).

Figure S.52 Diagram of placement of Nitinol stent in blood-vessel.

Shark

[biomedical, general] Group of aquatic animals (i.e., fish) characterized by a cartilaginous skeleton, that in general has a highly evolved sensory system that relies on electrosense functionality; defined as electroreception, the ability to sense electric and MAGNETIC fields. Sharks also possess a pectoral fin that is not fused to the head, which increases its maneuverability. The electrosense is also found in birds to provide navigation. The shark uses the electrosense to detect prey based on cellular DEPOLARIZATION and muscular contraction. The sensing organ is modified epithelial tissue that forms specific sensory ELEMENTS call the Ampullae of Lorenzini. Certain well-known sharks are great white shark, tiger shark, mako shark, nurse shark, whale shark, and the hammerhead shark (see Figure S.53).

Figure S.53 Diagram of sensing organs of certain sharks used for detection of electromagnetic waves, both earth's magnetic field (static) and muscular contraction (dynamic; believed to reach up to 2 km distance in detection range).

Sharp series

[atomic, nuclear] Fine structure of spectral lines within the DOUBLET ATOMIC EMISSION lines of alkali metals representing transitions between the n^*s and the $2p$ electron configurations. This is placed in reference against the principal lines resulting from the n^*p to $2s$ electron configurations transitions, the diffuse lines of the transitions: $n^*d \rightarrow 2p$, and the fundamental lines of the $n^*f \rightarrow 3d$ transitions.

Shear flow

[fluid dynamics] For non-Newtonian liquids the stress appears as if it has a memory of prior conditions and the shear-stress is not a linear function of the flow gradient, however, depending on the LIQUID, become a function of the gradient as well as their derivatives; expressed in viscosity as $\eta(\dot{\mu}_s) = \eta(\dot{\mu})/\mu_s$, where $\mu_s = dx/dy$ is the shear strain and the rate of shear is $\dot{\mu}_s = [d(dx/dy)]/dt = D_{xy}$, also recognized as the velocity gradient.

Shear force

[biomedical, mechanics] Tangential component of a contact force, or the lateral force inside a deforming medium. Force that change the shape of an object without changing its volume. Shear stress is the ration of the shear force to the area involved, whereas shear strain is the ratio of deformation as the displacement of one level layer with respect to the DISTANCE to the fixed surface (see Figure S.54).

Figure S.54 Shear force: diagram of shear forces.

Shear Modulus (G_∞)

[acoustics, biomedical, computational, general, mechanics] Modulus of rigidity or stiffness. One of three parameters that are used to describe the stiffness and COMPLIANCE of a medium. The other two parameters are the YOUNG'S MODULUS and the BULK MODULUS. The shear modulus is defined as $G_\infty = \sigma_{xy}/\gamma_{xy} = (F/A)/(\Delta x/\ell)$, where $\sigma_{xy} = F/A$ is the shear stress, F the acting force parallel to the face of the object that is being deformed with surface area A , and the linear deformation of the position of the face with respect to the reference frame is Δx , which is applied over the height of the deformed object ℓ yields the shear strain: $\mu_{xy} = \Delta x/\ell = \tan \theta$, where θ represents the deformation ANGLE of the edge of the face plate with respect to the base (origin) of the object at rest. The Bulk modulus represents the response of a medium to an applied uniform pressure, whereas the Young's modulus defines the compliance in response to linear STRAIN (e.g., extension).

Shear Péclet number

[fluid dynamics, mechanics] See PÉCLET NUMBER, MASS TRANSFER.

Shear strain (μ_s)

[biomedical, fluid dynamics, general, mechanics] The ratio of lateral displacement (x) to the height with respect to the fixed surface (h): $\mu_s = x/h$ (see Figure S.55).

Figure S.55 Shear strain.

Shear stress (σ_s)

[acoustics, biomedical, fluid dynamics, general, mechanics] Ratio of SHEAR FORCE (F) to the surface area (A) that the force is applied to: $\sigma_s = F/A$. In ACOUSTICS the shear stress signifies the relative MAGNITUDE of the mean acoustic impedance across each respective layer or shear-surface (see Figure S.56).

Figure S.56 Shear stress.

Shear-thickening fluid

[biomedical, fluid dynamics] Non-Newtonian fluid for which the VISCOSITY (η) increases with the flow velocity gradient $D = \dot{\gamma} = [d(dx/dy)]/dt \equiv (dv_x/dx) + (dv_y/dy)$, in turn the viscosity (η) is defined to behave according to: $\eta = K_{\text{mat}} \dot{\gamma}^{n-1}$, K_{mat} a material constant (see DILATANT FLUID and NON-NEWTONIAN FLUID) (see Figure S.57).

Figure S.57 Shear-thickening fluid. Silly-Putty® dripping through a hole in a Plexiglas® plate. Other applications are found in novel body-armor designs.

Shear-thinning fluid

[biomedical, fluid dynamics] Non-Newtonian fluid for which the VISCOSITY (η) decreases with the flow velocity gradient D (also see SHEAR-THICKENING FLUID; see PSEUDOPLASTIC FLUID and PSEUDOPLAST) (see Figure S.58).

Figure S.58 Shear-thinning fluid.

Shedding frequency (ν_v)

[computational, fluid dynamics, mechanics, thermodynamics] Frequency of detachment of flow from a bluff or rounded surface such as under KÁRMÁN EDDY CURRENT VORTEX STREET development and maintenance. (see VORTEX SHEDDING FREQUENCY).

Shell model

[atomic, nuclear, solid-state, thermodynamics] The BOHR ATOMIC MODEL is constructed in shells, which are named in outgoing order as follows: K, L, M, N, O, P, and Q, corresponding with the PRINCIPAL QUANTUM NUMBER n , which is a positive integer and starts at $n = 1$ associated with the K-shell. The principal quantum number was the only QUANTUM NUMBER defined by NIELS HENRIK DAVID BOHR (1885–1962) in 1913 in his original atomic model. The electrons in the inner shell, the K-shell are tightly bound to the NUCLEUS and the most difficult to be excited, let alone extracted. The K-shell has only one SUBSHELL: 1s and can hold two electron only, with respective opposite SPIN. The orbital or azimuthal quantum number (second quantum number) of the K-shell is $\ell = 0$. The L shell consists of two subshells: 2s and 2p, providing for a total of two electrons in the 2s and six electrons in the 2p. The quantum number of the L-shell is $\ell = 1$. The M-shell has three subshells: 3s, 3p, and 3d, with the potential for harboring a total of 18 electrons (see BOHR ATOMIC MODEL) (see [Figure S.59](#)).

Figure S.59 Shell model.

Shepp-Logan phantom

[acoustics, biomedical, computational, general, imaging] Model of the human head introduced by Lawrence (Larry) Alan Shepp (1936–2013) and Benjamin Franklin Logan (1927–) in 1974 based on the geometric and Fourier decomposition of the general anatomical outline of the volumetric configuration of the generalized human head. The model has specific applications in validation of tomographic IMAGE reconstruction algorithms, specifically acting as attest-image for algorithm calibration in image

reconstruction with respect to TOMOGRAPHY (see POSITRON EMISSION TOMOGRAPHY [PET], COMPUTED TOMOGRAPHY [X-RAY CTR], and MAGNETIC RESONANCE IMAGING [MRI]) (see Figure S.60).

Figure S.60 Shepp-Logan phantom, three-dimensional rendering of the Shepp-Logan phantom used for image reconstruction algorithm testing shown in the image domain.

Sherwood number ($Sh = h_m L / D_{AB}$)

[biomedical, fluid dynamics] Dimensionless number identifying the concentration gradient at a surface, where h_m is the DIFFUSION rate, L the characteristic dimension, and D_{AB} the diffusion coefficient for the constituents A and B . The Sherwood number is the ratio of the mass DIFFUSIVITY with respect to the molecular diffusivity. In BLOOD flow the Sherwood number describes the PROBABILITY of SOLVENT desorption through the vascular WALL, where h_m now describes the wall permeability. The Sherwood number has various specialized definitions pertaining to specific geometries.

Shock absorber

[general, mechanics] Device that converts MECHANICAL ENERGY in other forms of energy, using fluid-flow or FRICTION mechanisms. The most well-known application of shock absorbers is on the axles of automobiles and motorcycles, compensating for unevenness in the road-surface and increasing the

traction stability by maintaining proper surface contact between the road surface and the tire surface (see Figure S.61).

Figure S.61 Shock absorber: (a,b) diagram of operation and examples of use.

Shock wave

[fluid dynamics, general] Abrupt change in pressure, generating a pulse propagation through a FLUID or a solid medium. One specific example is in EARTHQUAKE shock propagation. Other examples include the breaking of the sound BARRIER when flying and exceeding the Mach velocity, or bursting of a balloon. The shock-wave has an impulse due to the incremental change (see Figure S.62).

Figure S.62 Shock-wave.

Shunt

[biomedical, electromagnetism, fluid dynamics, general] By-pass mechanism that has the ability to mitigate risks and constraints that are present in the main line of a flow pattern. The flow can consist of fluids, charges, magma or gasses. On specific example of a biomedical fluid-dynamic shut is the bridging between a VEIN and an artery in the arm of a person with kidney problems to accommodate the high flow requirements for the KIDNEY dialysis equipment that is connected externally to the body (see [Figure S.63](#)).

Figure S.63 Kidney dialysis shunt in arm of patient.

SI units

[general] See SYSTÈME INTERNATIONAL (D'UNITÉS).

Sievert (Sv)

[biomedical, electronics, nuclear] Unit used in RADIATION exposure to indicate the biological effect, not specifically the MAGNITUDE of radiation. The SI unit for the combined quantity and mechanism of delivery (alpha, beta or gamma rays) of ionizing radiation that will produce the same biological effect in comparison to one rad of X-RAY radiation exposure. The scale compares to the unit gray used in X-ray exposure.

Sievert, Rolf Maximilian (1896–1966)

[biomedical, electronics, nuclear] Radiologist from Sweden. Sievert's work focused on the biological effects of RADIATION, introducing the biological equivalence, later assigned the unit Sievert. Sievert also introduced a standard for measuring ABSORBED DOSE of radiation, described by the "Kerma rate"; the kinetic ENERGY absorbed per unit mass. The AIR Kerma rate ($\dot{K}_{\text{air},P}$) is associated with nonionizing radiation (IONIZATION is secondary effect) in air, associated with photons, neutrons, and fast neutrons, expressed as $\dot{K}_{\text{air},P} = A_{\text{cc}} \Gamma_{\text{AKR}} \int_{\theta_1}^{\theta_2} (e^{-\mu_{\text{en}} d / \cos \theta} / P^*) d\theta$, where A_{cc} the "activity" of the source (rate of emission), Γ_{AKR} the Air-Kerma rate constant (this is linked to the exposure rate constant of the radiation), μ_{en} is the radiation attenuation coefficient, d is the source material thickness, $P^* = Lb'$, with L the length of the source, b' the DISTANCE from source to target, θ the angular field-of-view. A similar approach applies for water. This is important in brachytherapy, a form of RADIATION THERAPY where the radiation source is implanted in close

proximity to the volume that requires treatment; radiation seed implants as used for instance in prostate therapy (see [Figure S.64](#)).

Figure S.64 Rolf Maximilian Sievert (1896–1966), (a) in 1958. (Courtesy of Kungl. biblioteket, National Library of Sweden, Picture collection, KoB, Fc) and (b) photograph by Hans Weinberger.

Sigma particle

[atomic, nuclear] BARYON particle. Particle in the family of HADRON subatomic elementary constituents. Unstable hyperon with ELECTRIC CHARGE +2, +1, −1, or zero and strangeness −1.

Signal

[acoustics, biomedical, electronics, general, mechanics, optics, quantum] Stream (temporal) or distribution (spatial) of data. Signals can be described in one or more dimensions. A one-dimensional SIGNAL is an orderly sequence of numbers that describes the modulations and trends of a parameter. The successive acquisition of a physical quantity over time is the typical signal found in science and ENGINEERING. The temporal order of the numbers in a signal is a direct function of the order of events (i.e., measurements) in “time.” The characterization of a signal is defined by the order in which the data points are collected as well as the MAGNITUDE (amplitude) of the recorded numbers. Signal processing provides the tools to analyze the signal in order to extract important knowledge that may not be directly visible to the HUMAN EYE. One-dimensional signals are not necessarily ordered in time alone, the data-points may be location specific derived from a sensor array. The aspect of “time” forms the primary basis to describe the axis that identifies order. The temperature of a METAL rod as a function of location along the length is not directly a function of time, however the location-specific temperature may still be time dependent. In biomedical data acquisition the recording of the electrical activities of the DEPOLARIZATION of the HEART muscle is referred to as the ELECTROCARDIOGRAM (ECG), which is the main diagnostic signal in assessment of the cardiovascular system and general health, hence it is part of the “vital signs.” Multidimensional signals are the extensions or convolution of the one-dimensional signals. An IMAGE is a two-dimensional array of data. In a grey-scale image, the signal magnitude for a specified set of coordinates (x, y) identifies the level of brightness of the image at those coordinates, expressed by the response function $g(x, y)$. Signals identify the mechanism to obtain critical information about the origins of a phenomenon, based on the method of acquisition and the applied computational processing algorithm(s). Three types of signal can be recognized: analog, discrete, and digital. Analog signals are continuous both in time and amplitude, discrete signals are intermittent burst of continuous amplitude, the digital signal relies on encoding for the information, and both time

and amplitude are discrete. Neural impulses are a specific example of digital signals, whereas in most other scientific applications an analog-to-digital (AD) conversion is required (see Figure S.65).

Figure S.65 Signal.

Signal-to-noise ratio (S/N or SNR)

[acoustics, biomedical, electronics, general, mechanics, optics, quantum] Quality measure for the reliability and accuracy of a SIGNAL with respect to other measured data-points that are not directly related to the MAGNITUDE of a phenomenon (i.e., NOISE; also referred to as background, or background-noise). The signal-to-noise ratio is generally defined as the power (generally defined proportional to the AMPLITUDE squared) of the signal (P_{signal}) divided by the power of the noise (P_{noise}): $\text{SNR} = P_{\text{signal}}/P_{\text{noise}}$, for an alternating signal with mean amplitude zero the signal-to-noise ratio can be expressed as a function of the variance for the respective “signals”: $\text{SNR} = \sigma_{\text{signal}}^2/\sigma_{\text{noise}}^2$. In IMAGE processing a threshold for accuracy based on signal-to-noise is defined by the Rose criterion, stating $\text{SNR} \geq 5$ for well-defined feature analysis at 50% or better to distinguish the object from “background,” introduced in 1973 by the American physicist Albert Rose (1910–1990). The ratio is usually expressed in DECIBEL (dB): $\text{SNR}_{\text{dB}} = 10 \log_{10}(P_{\text{signal}}/P_{\text{noise}})$. Noise can be thermal (e.g., electronic influence produced by charge agitation) or result from the ambient conditions, such as equipment switching or in ACOUSTICS the voices of bystanders. Noise is a random feature that can provide a large magnitude data point produced by the equipment used to collect the features representing specific physical consequences (see Figure S.66).

Figure S.66 Signal-to-noise ratio: example of sinusoidal signal with imbedded noise, and noise alone.

Silastic™

[biomedical, chemical, mechanics] Highly configurable, inert silicone rubber, specifically used in prosthetic devices. Introduced by Dow Corning®.

Silicon (Si)

[chemical, solid-state] ELEMENT $^{28}_{14}\text{Si}$, metalloid, discovered in 1823. Electron configuration: $1s^2 2s^2 2p^6 3s^2 3p^2$; with electrons in the consecutive shells: 2, 8, 4. Silicon is the world's second most prevalent element, by mass (after oxygen), however virtually never found in pure form. The most common form is in silicate minerals, some forming the basis for what is known as sand. Silicon forms a major constituent in the popular chemical composite Silicone, as well its wide use in semiconductor design (see SILICONE RUBBER, SEMICONDUCTOR, and *pn*-JUNCTION) (see Figure S.67).

Figure S.67 Silicon wafer of semiconductor fabrication.

Silicon nitride

[biomedical, chemical] White chemically inert compound consisting of the ELEMENTS silicon and nitrogen (Si_3N_4), and may be classified as a ceramic. Silicon-nitride is a solid with a high-melting-point of $\sim 1900^\circ\text{C}$. Silicon-nitride has excellent shock RESISTANCE and high durability and is used in many applications that have impact or VIBRATION risks, such as the automotive industry (e.g., cylinder lining, bearings) and medical devices as an alternative to TITANIUM and PEEK (polyether ether ketone), and is used for instance in orthopedic applications such as spinal FUSION devices.

Silicone rubber

[biomedical, chemical, mechanics] Mixed inorganic–organic ELASTOMER composed of a silicon-POLYMER, consisting of the ELEMENTS silicon (Si), CARBON (C), hydrogen (H), and oxygen (O), based on a silicon-oxygen backbone. Silicone has the following generic chemical formula $[\text{R}_2\text{SiO}]_n$, where R represents an organic group, for instance: ethyl, methyl, or phenyl. Silicone has found many applications, ranging from house-hold sealers to medical applications, specifically breast augmentation inserts. The high temperature range makes the material very attractive, operational from -100°C to $+300^\circ\text{C}$. Silicone has very durable properties, including resilient chemical, mechanical and THERMODYNAMICS properties under a wide range of conditions and exposure to external influences. Silicone was first produced by Dow Corning® in 1943, and was invented around the turn of the century, beginning of the twentieth century by the British chemist Frederick Kipping (1863–1949) who also coined the term silicone. The concept was rapidly picked up by General Electric (GE), now under the company name “Momentive Performance Materials,” as well as “Wacker Chemie” and “Shin-Etsu Chemical” in the late 1940s and early 1950s. Only a select group of manufacturers produces Silicone. As a lubricant the most well-known form is polydimethylsiloxane

(PDMS), in OIL consistency. Recent advance introduced silicon in a self-healing elastomer format (see Figure S.68).

Figure S.68 Silicone rubber and example of use: gel.

Simple harmonic motion

[general] A MOTION is harmonic when the FORCE (F) on the object in motion is directly negatively proportional to the body's displacement (s), for instance under the influence of a spring-force or under GRAVITATION force (i.e., simple PENDULUM). The SPRING FORCE for a MASS-SPRING SYSTEM is defined by $F = -ks = ma$, where k is the spring constant and a the acceleration of the mass m . The displacement of the object around the point of equilibrium ($s = 0$) needs to be small enough to satisfy $F(s) = \left[\frac{dF(s)}{ds} \right]_{s=0} s$. The motion needs to satisfy the following equation: $(d^2s/dt^2) + (k/m)s = 0$. The motion by the body varies sinusoidally with time and can generally be described by sine and cosine functions or in complex notation including the range of motion called AMPLITUDE (A), the FREQUENCY ($\nu = \omega/2\pi$) (or angular frequency: $\omega_0 = \sqrt{k/m}$, also called the NATURAL ANGULAR FREQUENCY), period ($T = 2\pi/\omega$) and PHASE ($\omega t + \phi$; with phase constant: $\phi = \tan^{-1}(\omega s(t)/v(t))$, with) of the location, all as a function of time; that is, $s(t) = A \sin(\omega t + \phi)$. For the simple pendulum with length: ℓ , the harmonic deviation is in the ANGLE: θ the harmonic oscillation satisfies: $(d^2\theta/dt^2) + (g/\ell)\sin\theta = 0$, which for small deviations reduces to: $(d^2\theta/dt^2) + (g/\ell)\theta = 0$. Harmonic oscillators appear in many locations, on an atomic level it accounts for the temperature effects, while RESONANCE plays a major role in musical instruments, whereas most phenomena are damped oscillations. An OSCILLATION under constant reinforcement (i.e., applied mechanism of force) will result in resonance (*also see* MASS-SPRING SYSTEM) (see Figure S.69).

Figure S.69 Illustrations of simple harmonic motion with wave pattern.

Simpson's rule

[computational] Method used in NUMERICAL integration, providing exact solutions up to polynomials of the third power. Simpson's rule is most elegantly implemented by integration of a third-order Lagrange interpolating polynomial fit ($f(x)$) to the base function of the integral, taken at three points, performing the equivalent linear interpolation at three equally spaced points, separated by a DISTANCE ℓ :

$$\int_{x_0}^{x_1} f(x) dx = \int_{x_0}^{x_0+2\ell} f(x) dx = \frac{1}{3} \ell (f_0 + 4f_1 + f_2) + \frac{1}{6} \int_{x_0}^{x_1} (x_0 - x')^2 (x_1 - x') f^{(3)}(x') dx' \\ + \frac{1}{6} \int_{x_0}^{x_1} (x_2 - x')^2 (x_1 - x') f^{(3)}(x') dx' = \frac{1}{3} \ell (f_0 + 4f_1 + f_2) - R_{\text{rest}}$$

where f_n represents the function at the respective interpolation points: $f_n = f(x_n)$, and $R_{\text{rest}} = (n\ell^5/90)f^{(4)}(x^*)$ the error term using the fourth order derivative.

Simulated annealing

[computational] Mathematical approach in PROBABILITY used for solving problematic SOLUTION techniques involving combinatory methods. It may be improbable to find an optimal solution, however a reasonably good solution may be derived under simulated annealing probability optimization. One particular example is the process of mimicking misplaced atoms in a METAL undergoing heating followed by a slow cooling process, often termed the "traveling salesman" problem. The salesman must optimize (minimize) the mileage traveled for work based on the itinerary spread over randomly located locations in multiple cities, this is done by pairwise trading the order of visits, finding a local minimum, without ever reaching a global minimum. Certain trades in the order in which places are "visited" may have no impact on the direct outcome, but may lead to reductions further down the path.

Simultaneity

[nuclear, relativistic] Under relativistic concepts two events that happen at the same time (e.g., two simultaneous observations) may not be perceived as simultaneous for two different observers due to two different concepts of time for the respective observers.

Single photon emission computed tomography (SPECT)

[biomedical, imaging] Imaging modality that acquires information with respect to the concentration of radio-nuclides that have been previously introduced into the patient's body. SPECT has its origin in the early 1960s, when the idea of emission traverse section TOMOGRAPHY was introduced by the physician DAVID EDMUND KUHLE (1929–) and the engineer ROY Q. EDWARDS (mid twentieth century–) prior to the introduction of the imaging mechanisms of positron emission tomography (PET), X-RAY computed tomography, or magnetic resonance imaging (MRI). SPECT imaging is inferior to PET because of attainable RESOLUTION and sensitivity. Different radionuclides are used for SPECT imaging that emit a single PHOTON (usually with ENERGY of about 140 keV), rather than positron emission (resulting in two high energy 511 keV photons) as in PET. Because only a single photon is emitted from the radionuclides used for SPECT, a special LENS known as a collimator is used to acquire the IMAGE data from multiple views around the body. The use of a collimator results in a tremendous decrease in detection efficiency as compared to PET. For positron emission tomography, location and collimation is inherently achieved by the fact that the pair of detected photons (gamma rays) can be traced back to their origin since they travel along the same line, in opposite direction, after being produced. In PET, in excess of 500 detectors are used to detect a PET ISOTOPE at any one time whereas in SPECT, there the imaging relies on only one or three collimators. Although the SPECT imaging resolution is not nearly as high as that of PET, the availability of specific SPECT radiopharmaceuticals, and the economic aspects of SPECT as well as the practical implications of the instrumentation make this mode of emission tomography particularly attractive for clinical studies of the brain. The cost of SPECT imaging is about one third that of PET.

Single photon photoelectric effect

[general] The photoelectric effect is the result of photons liberating electrons from the VALENCE BAND of a METAL. The MINIMUM ENERGY requirement for the generation of a PHOTOELECTRON is called the work-function and is a function of the material: $E_{\text{work}} = h\nu_0 = \phi_w$, where $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ is PLANCK'S CONSTANT, ν_0 the threshold frequency of electromagnetic RADIATION. A single photon can generally liberate only one electron (conversion into kinetic energy), where sometime multiple photons of low energy can combined release an electron. Since the photoeffect can be considered to be a single photon effect the total number of photons is generally immaterial to the energy of the ejected electron.

Single-slit diffraction

[general, optics] Experimental design first executed by JOSEPH VON FRAUNHOFER (1787–1826) around 1814. The far-field INTERFERENCE pattern resulting at a distant screen can be interpreted as having an infinite number of individual sources spread out over the width of the opening of the slit, creating individual Huygens wavelets (see HUYGENS PRINCIPLE). The locations of the minima (dark space) resulting from cancellation interference are spaced from the central maximum directly under the center of the slit described as $b \sin \theta = m\lambda$, where b is the width of the slit, θ the ANGLE with the central axis, m an integer, and λ the respective wavelength within the source LIGHT. The intensity measured electronically is defined as $I = I_0 (\sin \beta_{\text{Fr}} / \beta_{\text{Fr}})^2$, where $\beta_{\text{Fr}} = \pi b \sin \theta / \lambda$; note that the intensity of electromagnetic RADIATION does not exist, since there are two components to the WAVE; the MAGNITUDE of EM radiation is provided as radiance or fluence, depending on the geometry of impact. Compare to FRESNEL DIFFRACTION in the near-field (see Figure S.70).

Figure S.70 Graphical representation of the formation of the Single-slit diffraction pattern.

Singlet scattering length

[nuclear] During the RADIATIVE CAPTURE of an incident NEUTRON by a PROTON a characteristic length can be identified as the s-wave elastic triplet scattering probability (singlet): $a_{f(s)} = -f_{t(s)}(0)$, where $f_{t(s)}$ is the singlet scattering AMPLITUDE; $\hat{f}(k) = f_t(k)\hat{Q}_t + f_s(k)\hat{Q}_s$, with $\hat{Q}_t = (3\hat{I} + \hat{\sigma}^{(n)}\hat{\sigma}^{(p)})/4$, $\hat{Q}_s = (3\hat{I} - \hat{\sigma}^{(n)}\hat{\sigma}^{(p)})/4$, $\hat{\sigma}^{(n)}$, and $\hat{\sigma}^{(p)}$ the Pauli SPIN operators for the neutron and proton respectively, $\hat{I}$ the fourth row unit matrix; and k the wavenumber with $p = \hbar k$ the neutron momentum defined in the center-of-mass for the neutron-proton system, $\hbar = h/2\pi$, $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ is PLANCK'S CONSTANT.

Singlet state

[atomic, nuclear] Any pair of particles with spin-1/2 can form total spin 1 in three different states, which is called a triplet, alternatively they combine to form a state of spin 0, the singlet state. The singlet state represents a TOTAL ANGULAR MOMENTUM of zero for a group of particles or represents a vanishing PARTICLE. The component can switch between triplet and singlet state multiple times during an extensive period and may prefer the singlet state. Oxygen however is preferably in TRIPLET STATE, however a singlet state can be configured, which is poisonous to many biological systems, specifically used in cancer therapy. Singlets occur both in atomic and nuclear configurations. In hydrogen two electrons are antiparallel in the ground-state forming a singlet, however the protons are in triplet state, creating an ENERGY configuration that is degenerate (see Figure S.71).

Figure S.71 Diagram of singlet atomic state of excitation and energy transfer states. The singlet state is highly reactive and in photodynamic therapy, singlet oxygen is the reactive oxygen that initiates the break-down of the cellular nucleus by oxidation and decay, resulting in cell-death.

Singularity

[computational] Location in space where a mathematical function (and hence the described phenomenon) cannot exist. In calculations these points will need to be avoided. For instance the expression $1/r$ will let the function go to infinity at the origin (see Figure S.72).

Figure S.72 Example of singularity: worm-hole diagram, galactic space discontinuity.

Sink and source

[fluid dynamics] Modeling concept in fluid-dynamics describing the flow pattern definition with respect to a theoretical source. In case the source is negative this becomes a sink. The velocity profile expressed in spherical coordinates is $v_r = \Lambda/2\pi r$ and $v_\theta = 0$, where r is the radius to the center of the phenomenon, and Λ the source strength, specifies the rate of volume flow going outward with respect to the source; when negative the flow is inward. The corresponding flow potential is $\phi(r, \theta, \phi) = (\Lambda/2\pi) \ln r$, and the **STREAM FUNCTION** is defined as $\psi(r, \theta, \phi) = (\Lambda/2\pi)\theta = (\Lambda/2\pi) \arctan(y/x)$.

Skeggs, Leonard T. Jr. (1918–)

[biomedical, chemical] Chemist from the United States. Skeggs received recognition for his discovery of two angiotensin peptides in relation to hypertension (high blood-pressure, predominantly with respect to a **SYSTOLIC PRESSURE** over 140 mm Hg, but a **DIASTOLIC PRESSURE** exceeding 90 is gaining more importance) through the angiotensin converting enzyme. Additional work of Skeggs resulted in significant improvements in **KIDNEY** dialysis procedures (see [Figure S.73](#)).

Figure S.73 Leonard T. Skeggs, Jr. (1918–).

Skeletal muscle

[biomedical, mechanics] In tissues there are three prominent types of muscles, skeletal muscle, cardiac muscle and smooth muscle. Skeletal muscle is attached to the bone structure of vertebrate animals and provides a mechanism to apply force and torque and yield movement and displacement (see **MUSCLE**).

Skin

[biomedical, chemical, general] Part of **ANATOMY**, organ for many classes of animals, primarily applies to vertebrates. Most known for the human skin. The skin is a multilayered structure with several attributes, such as imbedded sensors for touch, temperature, pressure as well as vascular integration to provide nourishment to sustain the biological functions. Parts of skin are semipermeable membranes that allow sweat

to pass through but also provide a mechanism for chemical interaction (e.g., allergens) and specifically drug delivery. Skin can have a specific COLOR resulting from dye MOLECULE concentrations called carotene and melanin, in collaboration with hormonal influences, such as androgens. For humans the skin is the second largest organ next to the lung in surface area. Skin has three layers: the outermost layer epidermis; directly beneath the epidermis is the dermis, containing connective tissue, hair follicles, and sweat glands; the deeper hypodermis primarily consists of fat and connective tissue. The epidermis forms a waterproof BARRIER and form the skin-tone. The skin has certain electrical, physiological, and chemical properties that are used for diagnostic interventions as well as derived applications. Some of the nonspecific applications are in the lie-detector test, and more recently in bioelectric power supply for in situ monitoring devices (see Figure S.74).

Figure S.74 Skin, human skin diagram of anatomical structure.

Slater determinant

[atomic, chemical, mechanics] An expression that describes the wavefunction (as SOLUTION to Schrödinger's equation) of an anti-symmetric system consisting of *more than two* fermionic configurations (e.g., electrons) that consequently satisfies the PAULI EXCLUSION PRINCIPLE. The anti-symmetry and Pauli exclusion are rolled together in the fact that the system changing sign when exchange of fermions takes place. The principle was introduced by John C. Slater (1900–1975) in the 1930s. The principle relies on approximation of the WAVE function for a many-particle system by SEPARATION OF VARIABLES, implementing the product of orthogonal wave functions of the individual particles that may be chosen appropriately based on the local conditions.

Specific applications are in atomic orbits and molecular electron orbits. The radial function is as follows: $R(r) = Nr^{n-1}e^{-\chi r}$, where n has the function of PRINCIPAL QUANTUM NUMBER, N a NORMALIZATION factor, r the radius, and χ provides the charge compensation for the NUCLEUS. The angular aspect of the Slater determinant is expressed in POLAR COORDINATES by the spherical harmonics: $Y_l^m(\vec{r})$. Also known as Slater orbital.

Slice

[imaging] Segment of computed TOMOGRAPHY data acquisition array that has one narrow dimension that is part of a stacked organization to form a three-dimensional reconstruction (see, for instance, PET, MRI, and X-RAY COMPUTED TOMOGRAPHY) (see Figure S.75).

Figure S.75 (a) Representation of the “slice theorem” concept in imaging, where the object is sliced as if it were a piece of fruit. (Continued)

(b)

Figure 5.75 (Continued) (b) The slice thickness (Δz) will determine the lateral resolution as exemplified for the magnetic resonance imaging diagram as a function of frequency modulation (Δf). Generally the slices are presented next to each other for evaluation.

Smoke method

[fluid dynamics] Visualization method for illustrating TURBULENCE effects. In gaseous FLUID flow the use of a smoke wire placed in the lumen of the flow can highlight the flow patterns. A specific example is the

formation of a torus of smoke indicating fluid rolling around a circular axis; or less prominent, spinning around an imaginary axis line that forms a closed loop (see [Figure S.76](#)).

Figure S.76 Example of the Smoke method.

Smyth report

[atomic, nuclear] Report on the MANHATTAN PROJECT by the American physicist Henry DeWolf Smyth (1898–1986), focusing on the Allied Forces effort in World War II to develop the ATOMIC BOMB (see MANHATTAN PROJECT).

Snel ("Snell"), Willebrord Snel van Royen (Snellius) (1591–1626)

[optics] Scientist and mathematician from the Netherlands. Snell described the path of LIGHT at the interface of two media with a discontinuity in index of refraction in 1621. Willebrord Snell changed his name to the Latin equivalent: Snellius in celebration of his scientific achievement. The work of PTOLEMY (90–168) and IBN SAHL (940–1000) may be considered to predate that of Snell but these scientists lacked the proper instrumentation at the time to define the exact geometric relationship mathematically. Additionally, RENÉ DESCARTES (1596–1650) described similar concepts in 1637 (see [Figure S.77](#)).

Figure S.77 Willebrord Snel van Royen (1591–1626).

Snel's Law

[acoustics, general, optics] See **SNELL'S LAW**.

Snell's law

[acoustics, general, optics] **LAW OF REFRACTION** discovered by **WILLEBRORD SNEL (SNELLIUS) VAN ROYEN** (1591–1626) described as $\sin \theta_i / \sin \theta_r = n_2 / n_1$, where θ_i is the **ANGLE** of incidence with respect to the normal to the surface at the interface between two media, incidence media with index-of refraction n_1 and continuing medium with index-of refraction n_2 , and θ_r is the angle of refraction into the second medium. The index of refraction will depend on the material properties of the medium as well as the **WAVE** phenomenon itself (e.g., mechanical, electromagnetic) (see [Figure S.78](#)).

Figure S.78 Snell's Law.

Socrates (469–399 BC)

[general] Philosopher from Greece, born in Athens. Recognized as one of the architects of analytical thinking, sciences and western philosophy (see [Figure S.79](#)).

Figure S.79 Artist representation of Socrates (469–399 BC).

Soddy, Frederick (1877–1956)

[atomic, chemical, nuclear] Physicist and radiochemist from Great Britain. Soddy introduced the term ISOTOPE, explaining the RADIOACTIVE DECAY of certain ELEMENTS that have the same location in the periodic table, in collaboration with ERNEST RUTHERFORD (1871–1937). Fredrick Soddy received the Nobel Prize in Chemistry in 1921 for his contributions in the understanding of the RADIOACTIVITY in chemical substances and the pertaining chemical configuration (see [Figure S.80](#)).

Figure S.80 Frederick Soddy (1877–1956). (Courtesy of University of Glasgow, *College Courant*, the journal of the University of Glasgow Graduates' Association, no. 64, March 1980.)

Sodium ($^{22}_{11}\text{Na}$)

[biomedical, chemical, nuclear] Metallic element (Latin: Natrium). Silver white ALKALI METAL. The HUMAN BODY in particular uses sodium to mitigate BLOOD PRESSURE as well as blood volume. Sodium also serves as a catalyst in the operation of muscles and provide nerves with a chemical means to maintain a trans-membrane potential and form an ACTION POTENTIAL. Sodium was discovered in 1807 by HUMPHRY DAVY (1778–1829) as the result of the ELECTROLYSIS of sodium hydroxide (inorganic compound, commonly found as caustic soda; lye. Frequently used in detergents). Sodium is abundant on EARTH and ranks sixth as the most liberally available substance, most commonly found in “table-salt”: sodium chloride. Sodium has

a very prominent yellow spectral line (D line at $\lambda = 589.3$ nm), which is sometimes used in street LIGHT illumination (*see* SODIUM, ENERGY LEVELS) (*see* Figure S.81).

Figure S.81 Sodium crystal.

Sodium chloride (NaCl)

[biomedical, chemical] SALT, compound that easily dissociates into the ions Na^+ and Cl^- in water, certain alcohols and glycerol to name a few. Major component of biological system, specifically human BLOOD, and hence used as constituent in buffered Saline SOLUTION for infusion during hospitalization. As for most salts our tongue has specific sensors for metallic salts (including and highly sensitive for NaCl), as one of the five main “flavors.”

Sodium cooled reactor

[nuclear] Nuclear reactor power plant that uses liquid Sodium as a coolant for the REACTOR process. Nuclear power plants use coolants to make the heat generated from the core available for power generation in steam turbines. Coolants also maintain a controllable pressure within the core of the reactor (see NUCLEAR REACTOR) (see Figure S.82).

Figure S.82 Nuclear reactor diagram with a heat exchange between the internal sodium cooling and the external water cooling driving the steam reactors. One of the alternatives is a pressurized “heavy” water internal cooling.

Sodium iodide detector

[nuclear] Device used to measure radiation based on “scintillation” principles resulting from interaction of RADIOACTIVE DECAY with the ENERGY bands in the sodium iodine crystal, which generate photons that pass through a photomultiplier for gauging the MAGNITUDE of the incident radiation. Generally this type of detector ranks behind the gas-filled detector, which uses IONIZATION for detection, measured by an ANODE in a current meter set-up.

Sojourner

[astrophysics/astronomy, general] Robotic MARS rover delivered by the Pathfinder spaceship in 1997 used for extensive Mars exploration (see [Figure S.83](#)).

Figure S.83 Sojourner.

Solar power

[thermodynamics] The systematic use of the LIGHT from the SUN to produce ELECTRICITY resulting from the PHOTOELECTRIC EFFECT. The photoelectric effect was described by Alexandre-Edmond Becquerel (1820–1891), a physicist from France, observed the photoelectric effect in 1839. Solar panels are used in various sizes to power portable gear during camping trips or supply an entire city of all the electricity requirements for normal operation. To date the best ENERGY conversion for solar cells is in the order of 24%. Solar power relies on the photoelectric effect for the generation of electricity. The Romans built glasshouses in the thirteenth century. The first documented solar collector was built in 1767 by the scientist Horace-Bénédict de Saussure (1740–1799) from Switzerland. Horace de Saussure developed large cone shaped collectors that used ammonia which would boil to perform work acting as a locomotion or perform

refrigeration. In 1861 Auguste Mouchout (1825–1911) developed a steam ENGINE powered by solar energy alone (see [Figure S.84](#)).

(a)

(b)

Figure S.84 Solar power: (a) solar farm and (b) solar-powered airplane, combining the solar energy to power flight in addition to the aerodynamics of the design of the plane and the mechanical integrity to withstand shear stress from wind turbulence. (Courtesy of Solar Impulse®, Lausanne, Switzerland.)

Solar system

[computational] Galactic arrangement of the planets orbiting our SUN, from the inside out, Mercury, VENUS, EARTH, MARS, JUPITER, SATURN, Uranus, Neptune, and Pluto. Earlier models were GEOCENTRIC, the most well described of this kind was by PTOLEMY (approximately 90–168 AD) published around 140 AD. The first attempt to account for the deviations in the Ptolemy model by placing the Sun in the center of the planetary revolutions was by the “Polish”/German (Prussia) scientist NICOLAUS COPERNICUS (1473–1543; Niclas Koppelnigk) suggesting a HELIOCENTRIC model, published in 1543 (“*De Revolutionibus Orbium Coelestium*”), but presented the idea in the late 1400s to early 1500s. Based on the observations by the German astronomer and mathematician TYCHO BRAHE (1546–1601) in the late 1500s the foundation was

made for a rigorous description of a solar centered planetary system, introduced by JOHANNES KEPLER (1571–1630) in 1609, using the unpublished data from Tycho Brahe (see [Figure S.85](#)).

Figure S.85 Solar system.

Solar therapy

[biomedical, chemical, optics] Use of sun-light to treat SKIN disorders. Even though the beneficial effects of sunlight to the body for general health as well as for therapeutic applications to skin diseases (e.g., psoriasis, acne) and general benefits to mood were known for millennia by the Egyptians, healers in India and China the scientific description was provided by NIELS RYDBERG FINSEN (1860–1904). The use of sunlight later progressed on to artificial light-sources in PHOTODYNAMIC THERAPY.

Solar wind

[astrophysics/astronomy, general] RADIATION pressure that exerts a force on ionic material, charged PARTICLE content, primarily resulting from the SUN due to the high radiance. The pressure inflicted by electromagnetic radiation can be defined based on absorption or REFLECTION, where the impulse of reflection is twice as large, respectively expressed as $P_{\text{solar}} = S/c$, where $\vec{S} = (1/\mu_0)\vec{E} \times \vec{B}$ is the Poynting vector (equivalent power flux), $\vec{E}$ the electric field, $\vec{B}$ the MAGNETIC FIELD, $\mu_0 = 4\pi \times 10^{-7}$ H/m the permeability of free space, and c the speed of LIGHT; alternatively $P_{\text{solar}}^{\text{reflect}} = 2(S/c)$. The solar wind will divert the direction of the ION tail (ionized gasses etc.) of comets, but will have only minor effect on the dust tail which will be in-line with the path of the COMET. Generally, the solar wind is much greater than the gravitational attraction force.

Solenoid

[general] Wound helical coil that can generate a magnetic field ($\vec{B}$) when a current is applied through the wiring that makes the windings. The MAGNETIC FIELD distribution of a solenoid is very uniform and is described as a function of location as $\vec{B} = [\mu_0(N/\ell)I]/2(\sin\theta_2 - \sin\theta_1)\vec{j}$, $\mu_0 = 4\pi \times 10^{-7}$ H/m the permeability of free space, I the MAGNITUDE of the current, $\vec{j}$ the unit vector for the current direction, θ_1 and θ_2 respectively the ANGLE with the normal to the coil with respect to a point in free space where the magnetic field magnitude is

desired to be known, from either edge of the coil respectively, and N/ℓ the number of windings/turns N per length ℓ of the solenoid. Solenoids are often used to open and close by moving a METAL object through the core of the coil as a result of the attraction force described by AMPÈRE'S LAW, defining the magnetic field strength as a function of the applied current and the number of windings as a function of DISTANCE. The force resulting from a magnetic field on a charge is $F_{\text{magn}} = q\vec{v} \times \vec{B}$, with q the ELECTRIC CHARGE, $\vec{v}$ the velocity of the charge, which can be applied to EDDY CURRENT for ferromagnetic materials (see Figure S.86).

Figure S.86 Solenoid. (a) Simple solenoid as used on an automatic door-lock and (b) automobile starter with solenoid to "throw" the rotating starter gear into the teeth of the fly-wheel of the engine.

Solid angle

[computational, nuclear] The solid angle from a point O towards a surface area A with curvature C can be described by connecting the edges of the area A to the point of reference O . When a sphere is placed around the reference point O with radius r , this sphere will SLICE through the cone of lines connecting to the edge of area A . The MAGNITUDE of the surface area carved out by the cone has an area A' . In general the area of a sphere is $A = 4\pi r^2$. The area A' is also proportional to r^2 this way, since it is a fraction of the total surface area of the sphere. The solid angle Ω that is enclosed by the cone originating in O is defined as $\Omega = A'/r^2$. The units of the solid angle: Ω are steradians. The solid angle is independent of the shape of the surface, since it only demarcates the outline in space and relief has no impact on that, and it does not depend on the radius to the reference point (see Figure S.87).

Figure S.87 Solid angle.

Solid form of aggregation

[thermodynamics] The solid phase, one of the four states of a composite material or ELEMENT: gas, LIQUID, solid, and PLASMA.

Solidification

[thermodynamics] The process of converting a medium into solid state. Generally achieved by lowering the temperature below the FREEZING point.

Solid-state

[atomic, nuclear, thermodynamics] Sometimes also referred to as condensed MATTER, depending on the thermodynamic ENERGY balance.

Solid-state physics

[atomic, nuclear, thermodynamic] Branch of condensed MATTER physics dealing with the investigation of the properties of solids by means of for instance crystallography, QUANTUM MECHANICS. Additional mechanisms involve electromagnetism and more generally material science; which deals with mechanical properties such as hardness, elastic modulus, thermal conduction, electrical conductivity, and more under different thermodynamic and chemical conditions.

Soliton

[acoustics, computational, fluid dynamics, mechanics, quantum] A WAVE that acts as a PARTICLE. A solitary wave, which by definition are nonlinear in nature. Particular reference as a SOLUTION to the KORTEWEG—DE VRIES EQUATION (see [Figure S.88](#)).

Figure S.88 (a–c) Soliton, water wave progression (excerpts). (Courtesy of Onno Bokhove, Wout Zweers, with Anthony Thornton; University of Technology Twente, Enschede, the Netherlands.)

Solstice

[astrophysics/astronomy, general, geophysics] The astronomical events where the axis of the EARTH cantilevers to position the SUN directly over either the Tropic of Capricorn in the southern hemisphere marking the onset of winter or the Tropic of Cancer in the northern hemisphere, indicating the beginning of summer for the northern hemisphere. This indicates respectively the winter and summer solstice (see Figure S.89).

Figure S.89 Solstice.

Solute

[thermodynamics] Medium mixed-in with a SOLVENT to form a SOLUTION. The solute is dissolved in the solvent. The solute can be in the same phase (FLUID or GAS) as the solvent but has a smaller quantity either in mass or in volume.

Solution

[chemical, thermodynamics] Mixture of at least two substances, one usually a LIQUID, the other can be liquid, or solid, if the liquid is in gaseous form the SOLUTE (mixed-in substance, in this case identified by a smaller quantity) can also be a GAS. The mix of substances will be homogeneous. The solute can remain intact or dissolve into the ionic component that make the component, the most well-known example is the solute NaCl (SALT) in water. Solutions in water are referred to as aqueous solutions. The concentration of the solution is the quantity of the solute with respect to the solute, expressed in gram per liter or MOLE per liter. A saturated solution has reached the limit by which the solute's ions or molecules can be covalently bound to the solution and the solute will precipitate and condensate or solidify on the WALL of the container, primarily the bottom for solid solutes. The SATURATION or the amount of solute that can be dissolved in the SOLVENT is dependent on the temperature of the solvent. Cooling a solution can (and will, depending on the temperature range; some solutions have a very broad range of stable BINDING ENERGY balance) result in condensation of the solute. An IDEAL SOLUTION will adhere to RAOULT'S LAW; the partial (e.g., vapor-) pressure of a solution of a nonvolatile mixture is equal to the partial/VAPOR PRESSURE of the pure constituent/solvent at that temperature multiplied by its mole fraction. Raoult's law was introduced in 1882 by FRANÇOIS-MARIE RAOULT (1830–1901), a chemist from France.

Solvent

[thermodynamics] Liquid medium that allows MIXING with other medium LIQUID or solid or GAS to form a SOLUTION.

Somesthesia

[biomedical, mechanics] The ability to detect stimuli internal and external to the body. The stimuli can be thermal, mechanical, or even painful. This mechanism is part of the senses and is primarily serving the need for protection of the biological entity for instance is the stimulus sufficiently strong to damage tissues. An additional purpose of somesthesia is general experience of one's surroundings and the associated enjoyment or disgust based on the mental processing and predetermination.

Sommerfeld, Arnold Johannes Wilhelm (1868–1951)

[atomic, computational, fluid dynamics, general, nuclear] Physicist and mathematician from Germany. Arnold Sommerfeld provided significant contributions to the theoretical field of quantum PHYSICS and the description of atoms. He introduced the azimuthal QUANTUM NUMBER with respect to atomic wavem-echanics, the second quantum number (ℓ), as well as the SPIN quantum number, the fourth quantum number (s). Arnold Sommerfeld was a contemporary of, and collaborator with Léon Brillouin (1889–1969). He also introduced the FINE-STRUCTURE CONSTANT, and pioneered X-RAY wave theory (see [Figure S.90](#)).

Figure S.90 Arnold Johannes Wilhelm Sommerfeld (1868–1951).

Sonic boom

[general] Acoustic WAVE generated as the result of the oscillating source overpassing the pressure WAVEFRONT when traveling at velocity exceeding the speed of SOUND with respect to the FLUID. The pressure wave can be described by the Rankine-Hugoniot relation as $P_2/P_1 = ([(\gamma_c + 1)/(\gamma_c - 1)](\rho_2/\rho_1) - 1) / ([(\gamma_c + 1)/(\gamma_c - 1)] - (\rho_2/\rho_1))$, where $\gamma_c = c_v/c_p$ the ratio of SPECIFIC HEAT under constant volume to the specific heat under constant pressure, P the pressure, and ρ the density in the respective locations (i). For ideal gasses (e.g., atmospheric AIR) this transforms under velocities (v) in the Mach range (exceeding the speed of sound) to: $(P_2 - P_1)/P_1 = 2[\gamma_c / (\gamma_c + 1)](Ma^2 - 1)$. See MACH NUMBER ($Ma = v/v_{\text{sonic}} = \sqrt{Re} \times Wi = v\sqrt{\rho/E}$; Young's modulus (E), also called Elastic modulus. In the definition

the following are also used: Re the REYNOLDS NUMBER and Wi the Weisenberg number) (see SHOCK-WAVE and MACH-CONE) (see Figure S.91).

Figure S.91 Sonic boom of airplane flight past, with condensation illustrating the rarefaction of the Mach cone.

Sonogram

[acoustics, biomedical, general, mechanics] Image obtained by ULTRASOUND imaging, primarily in medical diagnostics, also referred to as ULTRASONOGRAM. The IMAGE is formed by reflected PRESSURE WAVES that result from piezoelectric transducers placed in contact with the object under investigation. The trajectory of the pressure waves obeys SNELL'S LAW of REFLECTION and REFRACTION and can be collected at the same location where the pressure waves are generated. The ultrasound TRANSDUCER will intermittently emit pressure WAVE, and in the un-powered state there will be a quiet period in which the same transducer is used to detect the returning pressure wave. The time delay (Δt) between emission and detection will provide the DISTANCE (d) traveled from the source to the point of reflection based on the SPEED OF SOUND (v) defined by $d = v \times \Delta t$. Using the signals collected from various external positions correlated over time can be used to reconstruct the two-dimensional pattern of boundaries of mismatched INDEX-OF-REFRACTION, more specifically mismatched ACOUSTIC-IMPEDANCE resulting from layers of media. This process is accomplished by a sweeping or PHASED-ARRAY transducer. A linear transducer will generate a two-dimensional SLICE, which can be expanded using IMAGE REGISTRATION techniques to provide a lateral EXPANSION to the scan resulting from redirection of the pressure wave source orientation. Alternatively, a two-dimensional ultrasound array can provide a three-dimensional image virtually instantaneously. Ultrasound attenuates rapidly in a gaseous environment, which requires that the contact between the object and the transducer is directly

mechanical. ACOUSTICAL IMPEDANCE matched, direct mechanical contact is often accomplished by the use of an IMPEDANCE MATCHING gel placed between the ultrasound source and the test object. One of the primary sonographic applications is in tracking the growth rate of a fetus in the womb of a WOMAN. The pressure waves supposedly form minimal risk to the unborn child, whereas X-RAY or other IONIZING RADIATION or high power forms of ELECTROMAGNETIC RADIATION (i.e., MRI) can interfere with the development of the fetus (see Figure S.92).

Figure S.92 Sonogram. (a) Scanning motion over belly of pregnant woman and (b) three-dimensional reconstructed ultrasound image of baby in womb.

Sonography

[acoustics, general, imaging] See ULTRASOUND IMAGING.

Sonohysterography

[acoustics, general, imaging] Minimally invasive ULTRASOUND technique applying saline infusion. The saline forms a “impedance matching” condition, since AIR or GAS in human cavities creates significant ULTRASONIC IMAGING distortions due to scatter and attenuation. Specifically used to IMAGE the inside of a woman’s uterus. Saline is injected into the uterine cavity, by which means it is distended or enlarged. The saline impedance matching provides clear visualization of the outline of the endometrium (i.e., the lining of the cavity of the uterus), revealing polyps.

Sonoluminescence

[acoustics, energy] Specifically BUBBLE Sonoluminescence, the process of CAVITATION after bubble collapse where the acoustic ENERGY is converted in high-temperature atomic thermal agitation or even PLASMA formation and inherent emission of electromagnetic RADIATION.

Sørensen, Søren Peder Lauritz (1868–1939)

[chemical] Chemist from Denmark responsible for the initial concept of acidity and alkaline behavior of LIQUID, expressed as pH: $\text{pH} = -\log_{10} H^+$, based on the hydrogen ION concentration ($[H^+]$). This was later revised to use the hydrogen ion activity (see [Figure S.93](#)).

Figure S.93 Søren Peder Lauritz Sørensen (1868–1939) in 1918; photograph by Julie Laurberg (1856–1915) and Franziska Gad (1873–1921)—Royal Library, Copenhagen, Denmark.

Sound

[acoustics, fluid dynamics, general] Mechanical longitudinal waves generally considered operating in the frequency range 20–20,000 Hz. Sound is primarily acquired by the EAR (in both mammals and non-mammalian species), however the entire biological body is sensitive to mechanical vibrations and can sense sound COMPRESSION WAVES. Sources are vibrating solid objects, such as the vocal cords, GUITAR string and gaseous expansions such as electric spark discharges (e.g., LIGHTNING) and contractions such as during endothermic and exothermic chemical reactions. Sound can be recorded by electronic devices as well as mechanical means (e.g., needle attached to resonant fork carving pattern in for instance vinyl and wax) (*also see* HEARING). Sound is identified by the SPECTRAL CONTENT. Since sound devices will generate a FUNDAMENTAL FREQUENCY with associated higher HARMONICS which creates a SPECTRAL PROFILE. For instance in a string the fundamental frequency is directly correlated to the tension in the string, the cross-sectional dimension, the material(s) (certain strings are coaxially composed of various materials with specific structural characteristics, such as weave, braid, solid, etc.) and the length of the string. Sound has specific applications in music which has its own detailed phenomenological descriptions. Musical sound is denoted by splitting the spectral range in frequency interval such as octaves (from the Greek), which describes doubling the frequency in each step (i.e., fundamental to first harmonic = 1:2); in case the frequencies of two respective waves relate as 2:3 the ratio is called a perfect fifth *or* “quint” (e.g., a musical instrument can be tuned in “quint” setting), equivalently the ratios are segmented as: 3:4 = fourth *or* quart; 4:5 = major third *or* great tert; 5:6 = minor third *or* small tert, 3:5 = major sixth *or* sext; 8:9 = major second; 9:16 = minor seventh; 8:15 = major seventh and the 12th “note” 15:16 = minor second. All these tuning modes are segmented in six consecutive triads, building a 12 note chromatic scale as developed in the eighteenth century. This scale is also referred to as the Helmholtz pitch notation, developed by the German physicist HERMANN VON HELMHOLTZ (1821–1894). The 12 note mechanism was devised to build up a musical sequence using just one ratio, exemplified by the Thomas Young’s tuning formula (also known as Thomas Young’s 1799 well temperament). This supposedly has the advantage of making modulating between keys possible, however this aspect ratio segmentation does not hold exact. Two other segments were later added,

called tritons: 5:7 and 7:10. The current theoretical execution of the OCTAVE is thoroughly described in the works of Praetorius in 1619 (see [Figure S.94](#)).

Figure S.94 Examples of the principle of sound.

South magnetic pole

[general] See **MAGNETIC SOUTH POLE**.

Speaker

[acoustics, electronics, fluid dynamics, mechanics] See **LOUDSPEAKER**.

Special theory of relativity

[general, nuclear, quantum] See **THEORY OF RELATIVITY**.

Specific heat

[nuclear] ENERGY stored in lattice vibrations calculated from the Debye model is providing one specific aspect of the specific heat (C_v) = $(12\pi^4/5) N_A K_B (T^3/T_D^3)$, where $T_D = \hbar \nu_D/k$ is the Debye temperature; ν_D is the Debye frequency; $K_B = K = 1.38064852(79) \times 10^{-23}$ J/K is the Boltzmann constant; $N_A = 6.022140857(74) \times 10^{23}$ mol⁻¹ is the Avogadro constant; $C = \varepsilon T^{3/2}$, the low temperature “spin-wave” (MAGNETIC) specific heat, with T is the temperature, and ε is the ferromagnetic Debye coefficient; $C_e = \gamma T_e$ is the electronic heat capacity, with γ the reciprocal of the “RELAXATION TIME,” and T_e the “electron temperature” for the LATTICE vibrations. The total specific heat expression is as follows: $C = \gamma T + \varepsilon T^{3/2} + \beta T^3$ + correction, the correction will account for environmental variables and boundary conditions.

Specific heat (c_{sp})

[biomedical, general, mechanics, quantum, thermodynamics] The amount of heat that needs to be added to 1 g of material in order to raise the temperature of the material by 1 K, or sometimes also regarded as 1°C, to maintain accuracy in units: $c_{sp} = Q/m\Delta T$, describing the HEAT (Q) required to change the TEMPERATURE (T) of a MASS (m) by 1 K. The majority of this ENERGY is applied to increase the INTERNAL ENERGY with a rudimentary amount pertaining to work. The work effort is greater for heating under constant pressure than under constant volume, which applies primarily to gasses. Under very high temperature conditions the specific heat times the ATOMIC WEIGHT of all the respective chemical constituents is nearly constant, which is referred to as the LAW OF DULONG AND PETIT. This constant specific heat (“atomic heat”) results from the fact that at high temperatures the internal energy of atoms becomes approximately constant. This temperature phenomenon can be explained with QUANTUM THEORY.

Specific heat capacity (c_{sp})

[general] See **SPECIFIC HEAT**.

Specific resistance

[biomedical, electronics] The electrical RESISTANCE of a material with a length of 1 m and a cross-sectional area of 1 cm², this value is a characteristic value for the material. The specific resistance for copper at 18°C is 0.0000017 Ω .

Specific viscosity

[fluid-dynamics, mechanics] See VISCOSITY, SPECIFIC.

Specific weight

[general] The relative weight of a material/substance with respect to the weight of an equal volume of water at 4°C.

Spectroscopic ellipsometry

[imaging, material sciences, optics, solid-state] Diagnostic method for thin-film thickness determination as well as analyzing the location-specific chemical composition and film homogeneity. The spectroscopic analysis relies on polarization sensitive measurements of reflected electromagnetic RADIATION from interfaced between various layers of media, hence yielding the complex index-of-refraction of the respective media the LIGHT has traversed. Spectroscopic ellipsometry can be single-wavelength, which employs a MONOCHROMATIC LIGHT source, or multiwavelength. Ellipsometry determines the change in polarization of the light that is reflects from the layers of a stacked medium or from the transmitted light through a layer material structure. The POLARIZATION is generally defined by the relationship $\rho_{\text{pol}} = \tan(\Phi)e^{i\Delta}$. The polarization change is represented by means of the determination of the an AMPLITUDE ratio, Φ , as well as the PHASE difference, Δ , based on the complex index-of-refraction. The “ellipsometry” is defined by $\langle \tilde{\epsilon} \rangle(\lambda) = \sin^2(\vartheta) \left[1 + \tan^2(\vartheta) \{ (1 - \rho_{\text{pol}})/(1 + \rho_{\text{pol}}) \}^2 \right]$, which technically is a function of wavelength (λ) hence the spectral aspect. Furthermore, the process uses the fact that the index-of-refraction can be described under the Cauchy or Sellmeier relationship as $n(\lambda) = A + (B/\lambda^2) + (C/\lambda^4)$. The index of refraction is directly linked to the DIELECTRIC permittivity and follows the Kramers–Kronig description relating the dielectric permittivity to the molecular ENERGY configuration, in addition to being confined through SNELL’S LAW. The measured quantities are a function of the optical properties and thicknesses of individual material layers. Ellipsometry is primarily used to determine film thickness with the added benefit of identification of optical constants, thus providing details about the composition of each layer in particular DOPING concentration. Ellipsometry provides the sensitivity necessary to measure nanometer-scale layers, in particular used in quality control for wafer production in microelectronics. Next to this it is also applied to characterize crystallinity, and ROUGHNESS. Application of ellipsometry are found in analysis of flat panel display, biosensor, next to the optical coating industries such as solar polar construction.

Spectroscopy

[atomic, general, optics] In general spectroscopy stands for the spectral analysis of emitted light, and is equivalent in many ways to the PARTICLE phenomenon of COMPTON SCATTERING, both energetically and in spatial distribution. When intense MONOCHROMATIC LIGHT of frequency ν , illuminates a sample, it has been shown that light scattered from the sample not only contains RADIATION of frequency ν , but also weaker radiation of frequency $\nu \pm \nu'$. The weaker radiation components of the scattered light are known as the RAMAN SPECTRA. RAMAN SPECTROSCOPY is a measure of the frequency shift from the incident frequency. Assuming that incident photons carry sufficient ENERGY (directly linked to the wavelength; the shorter the wavelength—the higher the energy), a MOLECULE has the potential to absorb the energy from an incident PHOTON. The absorption results in an excited state for the molecule. The molecule prefers to revert to the lowest possible energy configuration, such as everything else in nature. However, instead of decaying with loss of all excitation energy by means of a full transition back down to the GROUND STATE, the molecule may prefer, based on energy conditions from neighboring molecules, make a transition down to another excited

vibrational state. The reemitted photon in this process depends on CONSERVATION OF ENERGY, and hence the (what is considered) scattered photon will be composed with slightly less energy with respect to the incident photon. The energy difference between the incident photon and the scattered photon matches the amount of energy required to bring the molecule in the higher energy excited vibrational state. The vibrational energy structure of the molecule can be gauged by determination of the frequency shift ν' with respect to the incident electromagnetic frequency ν . This vibrational energy structure (spectrum) for each molecule defines a fingerprint representing the molecular bonding within the specific sample. Several diagnostic techniques have been developed that are based on this specific and characteristic spectral profile by means of the spectral analysis of scattered light. Examples of certain diagnostic applications of Raman-Spectroscopy are for instance the in vivo analysis and characterization of chemical blood-gasses, next to BLOOD glucose sensing. Raman spectroscopy is frequently used in forensic sciences for the detection of toxic substances next to the comparison of sample with “culprit” in determination of cause and effect and quantification of probability of validity of correlations between various sources for the chemical constituents and mixtures. The latter technique can be called Raman spectroscopy assisted histology (see [Figure S.95](#)).

Figure S.95 (a,b) Spectroscopy.

Speed (v)

[general] Magnitude of the change in location as a function of time: $v = |dx(t)/dt|$, MAGNITUDE of the velocity vector. The time rate of displacement; DISTANCE moved per unit time. CGS unit: cm/s. The ANGULAR SPEED (ω) is the rate of change in the angular position (θ) of an object: ANGULAR VELOCITY: $\omega = |d\theta(t)/dt|$.

Speed of wave propagation in a confined liquid

[fluid dynamics] v_s , (FLUID DYNAMICS), speed of WAVE propagation in a confined liquid.

$v_s = \sqrt{(K/\rho)/(1 + (D/b)(K/E)\text{Const})}$, with the LIQUID flow density ρ , K the bulk modulus of the liquid with regard to compressibility, D the inside diameter of tube with wall-thickness b , E the Young's modulus of the flexible PIPE and Const a correction factor for dimensional and material factor affecting the speed of SOUND.

Spherical wave

[general, optics] $U(\vec{r}) = (A/r)e^{ik\vec{r}}$, where A a constant (i.e., AMPLITUDE), $k = 2\pi/\lambda$ the wavenumber, and $\vec{r}$ the vectorial DISTANCE to the source.

Sphygmomanometer

[biomedical, fluid dynamics] BLOOD PRESSURE sensing device based on application of external pressure in order to close off the blood-flow in the artery (specifically in the elbow of the arm) and subsequently reducing the external pressure. The principle relies on the pressure balance from the cuff applied to the tissue, where the pressure equilibrium ensures the sealing of the artery when the external pressure exceeds the internal pressure. The pressure inside the brachial artery is directly proportional to the applied pressure from the contractile MOTION of the HEART, the brachial artery is directly connected to the AORTA. As the pressure in the inflated cuff that is wrapped around the arm is reduced the pressure will reach a point where at the time of ventricular contraction the brachial pressure equates the applied pressure, which will be a function of the vascular health of the person as well as the heart function of the person under examination. At the high pressure equilibrium the SYSTOLIC PRESSURE will allow blood to flow under intermitted episodes, coinciding with the heartbeat. As the pressure in the cuff of the Sphygmomanometer is reduced even further at the low pressure an equilibrium with the DIASTOLIC PRESSURE will be reached, from which point onward (decreasing external pressure even further) the flow will be continuous. The sphygmomanometer was introduced in 1881 by Samuel Siegfried Karl Ritter von Basch (1837–1905) from Schechoslovakia/Austria (Prussian Empire) and refined by SCIPIONE RIVA-ROCCI (1863–1937) from Italy

with further refinements to the detection mechanism by the surgeon NIKOLAI KOROTKOV (1874–1920) from Russia in 1905. Also referred to as a Sphygmomanometer (*also see* KOROTKOFF SOUND) (see [Figure S.96](#)).

Figure S.96 Sphygmomanometer.

Spin

[atomic, general, mechanics, quantum, thermodynamics] Rotation of a solid object around its central axis. Examples of object with spin are a top, or a system of particles grouped together: electron constructed of ELEMENTARY PARTICLES, PROTON and NUCLEUS; next to the EARTH consisting of atoms and molecules. The rotation creates an angular momentum: $\vec{L} = I\vec{\omega}$, I the MOMENT OF INERTIA of the object with respect to the axis of rotation and $\vec{\omega}$ the angular velocity. The spinning MOTION presents a mechanism that counteracts a change in the ANGLE of the axis of rotation. This phenomenon is observed when the front wheel of a bicycle is lifted from the GROUND and made to rotate, while rotating there is the sensation of a torque in the opposite direction to the applied torque applied to turn the direction in which the wheel points. The angular momentum pointing perpendicular to the area of the wheel, pointing in the direction defined by the crotch-screw rule; following the rotation of the wheel with a crotch-screw will either move forward or backward from within the stopper in the wine-bottle. The angular momentum vector points in the direction of the advancement of the crotch-screw. The reactionary force resulting from the SPIN in response to the applied torque is defined through the right-hand rule, resulting in a torque in the opposite

direction with respect to the applied torque, making it difficult to turn the rotating wheel. Steering to the left generates a TORQUE (τ_F) to the right as a result of the change in orientation of the wheel as a function of time: $\tau_F = dL/dt$. This inherent property of the rotating (spinning) device for the basis for the uncanny and relentless stability of the GYROSCOPE. The first gyroscope was introduced in 1852 by JEAN BERNARD LÉON FOUCAULT (1819–1868) to illustrate the rotation by the Earth. Also, the inherent, intrinsic angular momentum of an atomic PARTICLE is identified by a QUANTUM NUMBER in modern atomic theory. The concept of “spin-up” refers to rotation from west to east, such as the earth’s rotation; in contrast “spin-down” refers rotation in the opposite angular direction. In atomic notation the concepts of spin-up and spin-down separates the energetic stages of two electrons in the same orbit, with identical BINDING ENERGY (based on the primary quantum number: n). For atomic notation the spin angular quantum number is s , with potential values of $s = +(1/2)$; $-(1/2)$. An object with spin exposed to external forces (torque) is generally subject to PRECESSION of the axis of rotation as well as NUTATION. The rocking and swaying motion under nutation is more broadly defined than precession, including for instance a wavy pattern embedded in the precession. The angular momentum for the spin of, for instance an electron in orbit with the HYDROGEN ATOM produces a MAGNETIC FIELD with magnetic angular momentum: $L_z = m_l \hbar$, m_l the MAGNETIC QUANTUM NUMBER and, $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK’S CONSTANT. The total orbital angular momentum in the Bohr model is defined by the ORBITAL ANGULAR MOMENTUM quantum number ℓ as $L = \sqrt{\ell(\ell+1)}\hbar$, $\ell = 0, 1, 2, \dots (n-1)$ (see Figure S.97).

Figure S.97 Spin.

Spring force

[general, mechanics] Force (F) resulting from mechanical deformation of a solid object, primarily compression/extension but also TORSION (e.g., McPherson strut) as well as compression or EXPANSION of a GAS in a sealed container with a plunger (gas-spring or gas SHOCK-ABSORBER), but also electrostatic spring. For the solid object the force is directly proportional to the mechanical displacement (x) defined linearly by HOOKE’S LAW as $F = -kx$, where k is the spring constant. For the electrostatic spring the spring constant is defined as $k = -(CV_b^2/d)$, where C is the capacitance, d the CAPACITOR gap and V_b the bias voltage. For a gas-spring (with a moveable plunger) the spring constant can be described as $k = \rho_m(\partial P/\partial \rho)(\mathcal{A}^2/V_m)$, with ρ the gas density, V_m the mean volume (<https://mospace.umsystem.edu/xmlui/bitstream/handle/10355/4560/research.pdf?sequence=3>) for high pressure as $k = PA/d$, with P the pressure, $\mathcal{A}$ the plunger-cross sectional area and d the displacement, however theoretically the frequency dependence will need to be incorporated for certain applications. For the volume of FLUID in a sound-pipe the spring constant is defined by

$k = \rho v_s^2 (A^2/V)$, where v_s is the speed of SOUND, A the cross-sectional area of the “organ pipe,” and V the volume of the device (see Figure S.98).

Figure S.98 Spring-force.

STANI

[acoustics] See SCANNING TOMOGRAPHIC ACOUSTIC MICROSCOPE.

Stanton number ($St = h/\rho v c_p = Nu_L/Re_L Pr$)

[energy, fluid-dynamics] Dimensionless number used for identification of the scale of HEAT TRANSFER to the thermal capacity of a FLUID, where h is the heat transfer coefficient, ρ the density, v the characteristic velocity, c_p the heat capacity, and Nu_L the Nusselt number, Re_L the REYNOLDS NUMBER and Pr the Prandtl number.

Stanton number, mass transfer ($St_m = h_m/v = Sh_L/Re_L Sc$)

[energy, fluid dynamics] Dimensionless number relating concentration differences to flow velocity, where h_m is the mass transfer coefficient related to the DIFFUSION rate, v the velocity, and Sh_L the Sherwood number, Re_L the REYNOLDS NUMBER, and Sc the Schmidt number.

Star

[astrophysics, atomic, energy, fluid dynamics, general, geophysics, nuclear] Galactic body that emits LIGHT and other electromagnetic RADIATION. The SUN is one of our most well-known stars and with the closest proximity for detailed investigation. The Sun radiates light resulting from proton-proton collision, forming a DEUTERON along with the emission of a NEUTRINO and a positive electron (positron). Stars can be quantified by size and ENERGY/surface temperature. The radiant emission: luminosity and surface temperature are generally directly proportional to the mass of the STAR. Examples of nomenclature in

star classification are: giant, super giant, QUASAR, and WHITE DWARF (dim, dense star near its end), and exploding star formations as novae and supernovae. Generally the life and death of stars can be described by a nuclear and a mechanical phenomenon. The nuclear aspect is the fact that the star gains its massive amount of energy and associated emission from NUCLEAR FUSION and NUCLEAR FISSION processes. The mechanical component is driven partially by the thermal gradient resulting in both convective mass and heat DIFFUSION. The nuclear processes eventually deplete the elementary constituents of the molten and gaseous amalgam resulting in an oscillatory behavior that changes character with the composition of the star. Pulsating stars are a clear and obvious example of this OSCILLATION phenomenon, whereas the process also takes place on smaller scales. Radial modes of oscillation are the most obvious and easily recognizable, however nonradial modes such as standing waves on the surface are also observed as well as running waves. The Sun has a standing WAVE on the surface with a period of 5 min, and other stars have radial waves with periods of days. Longer periods are also identified, and these are classified by the CEPHEID VARIABLES (see Figure S.99).

Figure S.99 Star. Galactic grouping of stars that was defined as the constellation Orion and our Sun.

Stark, Johannes (1874–1957)

[chemical, electromagnetism, general, solid-state] German physicist. Stark empirically verified the COMPTON EFFECT in 1909. Stark contributed to the explanation of the ENERGY splitting concept described by the Zeeman–Stark Effect, also described as the Star-effect. The work of Stark contributed to the basic

understanding of electron orbital structure and energy, chemical bindings and ATOMIC ENERGY structures (see [Figure S.100](#)).

Figure S.100 Johannes Stark (1874–1957). (Courtesy of University of Wurzburg, Wurzburg, Germany.)

Stark effect

[computational, electromagnetism, energy, general, solid-state] See **ZEEMAN AND STARK EFFECT**.

Starling, Ernest Henry (1866–1927)

[chemical, fluid dynamics] Chemist from Great Britain. Ernest Starling introduced the OSMOTIC PRESSURE effects in a system separated by a semipermeable WALL. The principles are similar to those described by JACOBUS HENRICUS VAN'T HOFF (1852–1911) and are outlined under the STARLING'S LAW (see [Figure S.101](#)).

Figure S.101 Ernest Henry Starling (1866–1927). (Courtesy of National Library of Medicine, Bethesda, MD.)

Starling's law

[chemical, fluid dynamics] Hydrodynamic flow of colloid solutions separated by a membrane as defined by ERNEST STARLING (1866–1927) in 1915. Also called the Starling equation and the Frank–Starling law, based on the contributions by Otto Frank (1865–1944). Fluid MOTION between two compartments separated by a SEMIPERMEABLE MEMBRANE is the result of the combined hydrostatic and osmotic pressure. The OSMOTIC PRESSURE is described by the JACOBUS HENRICUS VAN'T HOFF (1852–1911) VAN'T HOFF EQUATION and in modified format by the MORSE EQUATION. The hydrostatic pressure in the flow and pressure process with respect to the CELL MEMBRANE is derived by means of the principles of the Bernoulli equation. The porosity of the membrane (L_p), also referred to as membrane permeability, directly influence the passage of the solutes, mainly placing restrictions on the size of the particles and molecules that can be exchanged to influence the osmotic pressure. The OSMOTIC PRESSURE (Π) is the result of the following components in the SOLUTE exchange, TONICITY (quantity of dissolved salts, proteins and other chemicals), hydrostatic pressure of hemoglobin, BLOOD colloids, interstitial fluid hydrostatic pressure (resulting from muscular compression and volume extension next to gradient in elevation with respect to the point of exchange), interstitial FLUID colloidal solution. The filtration pressure (P_{filter}) resulting from the combined osmotic pressure ($\Pi = iMRT$, where i is the dimensionless VAN'T HOFF FACTOR, M the molarity of the solutes, $R = 8.3144621(75) \text{ J/Kmol}$ is the UNIVERSAL GAS CONSTANT, and T the temperature of the reaction and SOLVENT) and hydrostatic pressure (P^{hydro}) over a surface area (A) is describes as (see Figure S.102)

$$P_{\text{filter}} = \left\{ (L_p * A) * (P_{\text{capillary}}^{\text{hydro}} - P_{\text{interstitial}}^{\text{hydro}}) \right\} - \left\{ (A) * (\Pi_{\text{capillary}} - \Pi_{\text{interstitial}}) \right\}.$$

Figure S.102 Diagram illustrating the Frank–Starling law for the pump function of the heart, expressed as the cardiac function. The cardiac output, respectively the stroke volume, or stroke work are outlined by the vertical axis (y-axis). The horizontal axis (x-axis) generally denotes the end-diastolic volume. Alternatively, the x-axis can express the right atrial pressure, and sometimes is used to note down the pulmonary capillary wedge pressure as a parameter. The three curves indicate the change in preload, alternatively: afterload or contractility.

Static head

[fluid dynamics] For a PUMP, the maximum height the FLUID can reach under standard pump conditions. For a windmill used in drainage of low-lying areas (e.g., the Netherlands) the static head is approximately 1.5 m, which required placing these pumps in series with a moat separating two or more pump stages to overcome the technically feasible elevation of the LIQUID by the pump. Respectively, pumps used at drinking water wells can pump approximately against a static head of 20 m. Also known as hydraulic head. The static head is a pressure in liquid (most often water) column. This limitation can be overcome by using electric pumps in comparison to the use of windmills in the Netherlands to drain the low-lying areas north of Amsterdam as done by the hydraulic engineer from the Netherlands Jan Adriaanszoon Leeghwater (1575–1650) in 1607. A large water drain windmill in the Netherlands can pump approximately $38 \text{ m}^3/\text{min}$ against a static head of 1.3 m, such as used in the polders near Rotterdam, dating as far back as 1414. Note that windmill history can be traced back at least to seventh century Persia (see [Figure S.103](#)).

Figure S.103 (a) Jan Adriaanszoon Leeghwater (1575–1650), (b) static head and wind-mill pump, and (c) worm-wheel pump.

Stefan, Joseph (1835–1893)

[general] Physicist and mathematician from Austria (Slovenia). Joseph Stefan is known for his experimental contributions to radiation PHYSICS, in particular the Stefan–Boltzmann equation, with theoretical support from LUDWIG EDUARD BOLTZMANN (1844–1906) (see [Figure S.104](#)).

Figure S.104 Joseph Stefan (1835–1893).

Stefan–Boltzmann law

[atomic, nuclear] ENERGY OF PHOTON spectral emission power profile. The energy power profile is derived from integration of the Planck radiation law. Josef Stefan derived in 1879 that the radiance emitted from a blackbody is proportional to the fourth power of the ABSOLUTE TEMPERATURE of the blackbody as $\Phi^b(T) = \sigma_{\text{Stefan}} T^4$, $\sigma_{\text{Stefan}} = 5.67 \times 10^{-8} \text{ W/m}^2 \text{K}^4$ Stefan-Boltzmann coefficient/constant; with theoretical proof provided by LUDWIG EDUARD BOLTZMANN (1844–1906) in 1884; FLUX, units Watt per meter squared. The fully developed empirical and theoretical formula of the energy emission from a blackbody comes to $\Phi^b(T) = (2\pi^5 k_b^4 / 15b^3 c^2) T^4$, where $k_b = 1.3806488 \times 10^{-23} \text{ m}^2 \text{kg/s}^2 \text{K}$ the Boltzmann coefficient, $b = 6.62606957 \times 10^{-34} \text{ m}^2 \text{kg/s}$ the PLANCK'S CONSTANT, and $c = 2.99792458 \times 10^8 \text{ m/s}$ the speed of LIGHT. Alternatively the photon emission can be written as $\Phi_p^b(T) = \sigma'_{\text{Stefan}} T^3$, where σ'_{Stefan} represents the empirical Stefan-Boltzmann coefficient/constant for photon emission. The Radiance (L) of a body incident on an area A , under ANGLE of incidence θ , within solid angle Ω is linked to the Stefan-Boltzmann emission flux $\Phi^b(T)$ through: $L = \partial^2 \Phi^b(T) / \partial \Omega \partial \cos \theta$.

S

Stereo

[acoustics, general, optics] Primarily the three-dimensionally specified PERCEPTION of sound. Sometimes also used to describe depth perception by the combinatory effects from two eyes. The stereophonic HEARING is the result of the phase discrimination from the two ears with respect to the angular placement of the SOUND sources. As the EAR performs a spatially motivated FOURIER TRANSFORM of the acoustic WAVE based on the local sensitivity of the cochlea, the phase-discrimination will be a function of frequency. Human hearing as a frequency sensation has the ability to distinguish sounds that are less than 5 ms apart in time with respect to defining the individual acoustic events, whereas the wave RESOLUTION is better than 150 μs . Although in general the DEPOLARIZATION rate for the ORGAN OF CORTI in the BASILAR MEMBRANE of the cochlea of the ear is directly proportional to the stimulus frequency, the audio nerve cannot provide depolarization rates of 20 kHz, the upper limit of hearing. Three types of nerves can be identified for the SIGNAL transmission to the brain, one with frequency range around 700 Hz, one with frequency range around 1.3 kHz and one with frequency range around 10 kHz, with respective decreasing bandwidth for the higher transmission rates. The high response rate is tied into the frequency section for the high frequency detection close to the entry point at the oval window. This fact will be one of the limiting factors for phase

discrimination apart from the mechanical elastic dampening of the basilar membrane. The frequency hearing is in fact spatially defined by location on the basilar membrane. The locations on the basilar membrane are sensitive to one frequency only, with high frequency sensitivity at the cochlear base (oval window; modulated by the stapes from the INNER EAR) and low frequency sensation at the cochlear apex. Low frequencies (base) is not very useful in stereophonic detection due to the long wavelengths involved that are several times the dimensions of the human head. An acoustic wave in AIR of 20 Hz has a wavelength of 17 m, while 2000 Hz corresponds to 0.1717 m, based on the elastic modulus of air of $Y_{\text{elast}} = 1.41 \times 10^5 \text{ N/m}^2$ and density $\rho = 1.29 \text{ kg/m}^3$, or respectively a speed of sound $v_s = \sqrt{(Y_{\text{elast}}/\rho)} = 331 \text{ m/s}$ as experimentally verified. The use of two ears for humans can distinguish the PHASE of a single frequency of better than 90° , which will provide millimeter wave discrimination at the higher frequencies (note that the upper limit is approximately 10 kHz, at which the approximately wavelength is 3 cm with quarter wavelength resolution: 7.5 mm in the spatial domain; $<150 \mu\text{s}$ in the time domain) with associated spatial resolution of better than 5° in free space; whereas bats have a resolution of better than 1.5° . The auditory signal processing on a central nervous system and cranial level also applies a form of phase-locking for ultimate frequency discrimination and ensuing spatial resolution. All these auditory features provide the means for the human ear to mentally determine the location of the violinist, cellist, the trumpet player and the GUITAR player on the podium, as well as several other instruments. The location of the base drum is generally not specifically known from frequency information, however there is also AMPLITUDE information encoded that will assist in the spatial location determination using the phase locking mechanism-of-action of hearing. Humans can distinguish sound levels as small as 2 dB, specifically at low amplitude (note that 3 dB signifies half the amplitude). Even though stereo is primarily applied to hearing, however in theory stereoscopic VISION refers to the fact that with both eyes humans and other animals (e.g., mammals, birds, amphibians, and reptiles) can perceive depth, while insects with compound eyes have a very different signal processing concepts.

Stern, Otto (1888–1969)

[atomic, nuclear, quantum] German physicist who experimentally verified the QUANTUM THEORY, specifically for ELECTRON SPIN, in 1920, 2 years prior to the release of the official definition of electron spin, in collaboration with WALTHER GERLACH (1889–1979) (see [Figure S.105](#)).

Figure S.105 Otto Stern (1888–1969) in 1928, photographer P. Toschek.

Stern-Gerlach experiment

[atomic, nuclear, quantum] Experimental observation of a split in a beam of neutrally charged particles passing through a MAGNETIC FIELD. This experiment illustrated the inherent magnetic properties of the ATOM, and subsequently for electrons. The atomic MAGNETIC DIPOLE could be the only explanation for the split, based on the quantization of the angular momentum of the magnetic SPIN of the electrons, since the silver atom as used is balanced in electron configuration (BOHR ATOMIC MODEL). Since the beam of silver-atoms was split into two and this could only be attributed to the any single electron, hence the ELECTRON SPIN was baptized as $1/2$. The experiment was executed by OTTO STERN (1888–1969) and WALTHER GERLACH (1889–1979).

Stevin, Simon (1548–1620)

[engineering, general] Scientist and mathematician from the Netherlands. Simon Stevin was active in astronomy, GEOGRAPHY, mathematics, and logics. Stevin also introduced the Dutch word for mathematics: “wiskunde.” Simon Stevin published an all-encompassing review of mathematical approaches for ENGINEERING and PHYSICS in 1608 that were known up to that time from the early Greek philosophers, Arabic mathematicians, to more recent contributions, at least with supporting work from LEONARDO DA VINCI (1452–1519). The work predates the contributions from the range of well-known mathematicians that introduced their work in the mid and late 1600s and from there on: RENÉ DESCARTES (1596–1650), BLAISE PASCAL (1623–1662), GIOVANNI DOMENICO CASSINI (1625–1712), JEAN-BAPTISTE LE ROND D’ALEMBERT (1717–1783), JOHANN HEINRICH LAMBERT (1728–1777), JOSEPH LOUIS LAGRANGE (1737–1813) [comte de Lagrange], PIERRE-SIMON DE LAPLACE (1749–1827), and ADRIEN-MARIE LEGENDRE (1752–1833), in addition to a broad range of experimentalists that also supported their work with pure and applied mathematics. Also predating SIR ISAAC NEWTON (1642–1727) (see [Figure S.106](#)).

Figure S.106 Simon Stevin (1548–1620).

Stimulated emission

[atomic, optics] The encouragement (i.e., enhanced PROBABILITY) provided by a PHOTON that passes an excited electron state to release its ENERGY in the form of a photon. The stimulation process is based on the fact that the incident photon has an energy content ($E = h\nu$, $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK’S CONSTANT, ν the electromagnetic frequency) that is equal to or greater than the difference in energy between the excited state and the GROUND STATE of the electron in the unstable raised energy condition. When the medium of excited atoms/molecules only has one mechanism for EXCITED STATES than the released photon will by definition be identical to the stimulating passing photon. This latter condition provides the foundation for the LASER operational mechanism-of-action (see LASER).

Stirling, Robert (1790–1878)

[mechanics, thermodynamics] Clergyman and scientist from Scotland, Great Britain. Robert Stirling is known for the introduction of the closed-cycle ENGINE, also referred to as a external combustion engine. The closed Stirling process relies on a heat-exchanger for supplying the ENERGY to maintain the MOTION in the PHASE DIAGRAM (P-V diagram; pressure vs. volume), respectively temperature versus entropy diagram (T-S diagram) (see [Figure S.107](#)).

Figure S.107 Robert Stirling (1790–1878).

Stirling cycle

[thermodynamics] Gas compression cycle consisting of two isochoric (i.e., constant volume) step and two isothermal (i.e., constant temperature) segments. The process and ENGINE was patented by ROBERT STIRLING (1790–1878) in 1816. Compare to OTTO CYCLE and CARNOT CYCLE (see [Figure S.108](#)).

Figure S.108 (a) Stirling cycle. (b) Rhombic drive Beta type Stirling engine design. (Courtesy of Tobias.)

Stochastic process

[biomedical, computational, quantum] Events that are nondeterministic and are defined through a statistical PROBABILITY distribution. One specific example is BROWNIAN MOTION. Another being “RANDOM WALK” in optical simulation as illustrated by the use of a “Monte Carlo” simulation.

Stoichiometric coefficient, $(v_i^{(j)})$

[chemical, thermodynamics] In chemistry the Stoichiometric Coefficients are the constants in the reaction in relative proportions to form a product: $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$. In THERMODYNAMICS the Stoichiometric Coefficients $(v_i^{(j)})$ indicate the respective number of participating constituents (reactants) and products $[A_j]$, where the products have a negative value and the ingredients have a positive value so that the sum of the reaction balances at zero: $\sum_{i=1}^r v_i^{(j)} A_j(p) = 0$; where “ p ” indicates the PHASE of the component: GAS, liquid, or solid. Also known as Stoichiometric number.

Stoichiometry

[chemical, thermodynamics] Accounting of quantities of reactants and products in relative proportions with respect to chemical reactions. Stoichiometry is based on the law of CONSERVATION OF MASS. The total mass of the sum of all the reactants is equal to the total mass of all the products. This prescribes the relations among quantities of reactants and products in the form of a ratio of positive integers: $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$.

Stokes, George Gabriel, Sir (1819–1903)

[atomic, computational, fluid dynamics, general, optics] Irish mathematician and physicist. Pioneer in the mathematical description of FLUID flow, CREEP and optical phenomena such as diffraction. Additional work of Sir Stokes refers to the ENERGY loss in FLUORESCENCE with the associated longer emission wavelength than excitation wavelength. In the field of fluorescence he is best known for the STOKES LINES (see [Figure S.109](#)).

(a)

(b)

Figure S.109 (a) Sir George Gabriel Stokes (1819–1903). (b) Painting by Lowes Cato Dickinson. (Courtesy of Collection: Pembroke College, Cambridge, UK.)

Stokes drift

[fluid dynamics] In shallow water there is deviation from linear behavior in flow conditions. Liquid packages will be considered to circulate in closed loops during WAVE MOTION, however the particles moving with the wave motion and with the flow in the exterior of the WAVE have a higher velocity than LIQUID packages in the submerged part of the FLUID, which is moving in the opposite direction as the surface package flow and against the fluid-flow direction breaking the presumed circular package pattern. A net fluid-package motion can be defined that accounts for this nonlinearity in a second order phenomena. This phenomena also contributes to the description of the occurrence of undertow. The second-order liquid flow average velocity (v_{Stokes}) is described by the Stokes-drift as $v_{\text{Stokes}} = C_{\text{Stokes}} (a_w k)^2 e^{-2kh_a}$, where the average depth of the liquid level is h_a , the wavenumber is $k = 2\pi/\lambda$, C_{Stokes} is a constant and a_w is AMPLITUDE of the wave. When the wave amplitude is in the range of the depth of the water a phenomenon called wave-shoaling occurs. During wave shoaling the water waves are subject to refraction, generating so called longshore currents. This nearshore CIRCULATION can cause hazardous swimming conditions with longshore current velocities reaching 2.5 m/s, and rip current velocities on the order of 1.5 m/s. This DISPERSION is associated with the phase and group velocities and is linked to the high waves followed by low waves, generating a periodic fluctuation in water level, referred to as “surf beat,” a pulsation effect. These rip currents can have a history tracing outward into sea for over 1.5 km (see Figure S.110).

(a)

(b)

Figure S.110 (a,b) Ocean shoreline Stokes drift.

Stokes' Law

[atomic, computational, fluid dynamics, general] Description of the characteristic sedimentation speed (v) for a particle in suspension in LIQUID or GAS. Introduced by SIR G. STOKES (1819–1903). The process also applies to two liquids that do not mix (e.g., water and OIL), or the dissociation of gas/vapor-bubbles from a liquid. This applies for instance to centrifugation and can be formulated as $v = (2(\rho_p - \rho_\ell)gr^2)/9\eta$, where ρ_p

is the particulate (solved constituent) density, ρ_ℓ the density of the liquid, η is the VISCOSITY, r the PARTICLE radius, and g the GRAVITATIONAL ACCELERATION. For the removal of BUBBLES the approach needs to take into consideration the BUOYANCY acting against DRAG force.

Strain (ϵ_s)

[general] Deformation (ΔL) per unit length (L), used as linear strain: $\epsilon_{s,\ell} = \epsilon_{\text{strain},\ell} = \Delta L/L_0$, shear strain; the angular deformation $\epsilon_{\text{strain},\alpha} = \Delta\alpha/\alpha_0$, and volumetric strain; the change in volume per unit volume: $\epsilon_{\text{strain},V} = \Delta V/V_0$. Elastic strain will allow the medium to return to its original shape and size. Inelastic strain usually requires exceeding a threshold strain, at which point the deformation becomes permanent, or at least no full recovery is achieved upon unloading the applied stress. Under certain conditions the atomic configuration can be modified to become more resistant to elastic deformation, strain hardening. Strain hardening can be achieved by material treatment process, most well-known is a temperature treatment. Hardening can be induced by deformation at a temperature below the recrystallization temperature (cold-forming) followed by low-temperature heating, or by rapid cooling of low-carbon steel, both used for instance in the treatment of sword-blades by a blacksmith. The high temperature heating followed by rapid cooling is referred to as quenching and creates a hard but brittle structure (martensite). The cold-forming treatment creates a durable METAL (*also see* HOOKE'S LAW) (see [Figure S.111](#)).

Figure S.111 The strain principle.

Strain gauges

[general] Sensor strip that sends off an electrical SIGNAL on deformation. Strain gauges are made from piezoelectric ceramics materials as well as polyelectrolytes, metallic [microelectromechanical systems (MEMS)] and carbon-nanotube—POLYMER composites (e.g., PVA: polyvinyl alcohol; conductive PDMS: polydimethylsiloxane, with carbon backing), and gold nanoparticle composites and a range of electrically conductive materials. Other RESISTANCE strain gauges use a conductive material embedded in a flexible strip or band, for instance in biomedical applications the “mercury-in-rubber” gauge is popular due to its versatile applications for fitting around biological appendages (toes, fingers, ankle). Most of these applications rely on resistive changes for determination of degree of strain. A different variety of strain gauge uses capacitive coupling for two layers of thin material. Other mechanisms-of-action include fiberoptic LIGHT guides. The FIBER-OPTIC changes the local reflectivity on the core-cladding transition, changing the interferometric standing wave conditions. This type of fiber is extremely narrow and can be imbedded with little or no influence on the structural integrity. The fiber-optic strain gauge is used in monitoring the structural integrity of METAL or concrete bridges and buildings, as in polymer/fiberglass structures, such as race boats and racecars for safety information. The primary difference for the fiber-optic strain gauge is the location-specific information that can be imbedded in the optical signal structure for a single fiberoptic strand. The location-specific information is derived from multiplexing. Multiplexing is a technique that is also used in fiber-optic communications, carrying multiple signals simultaneously on a single fiber leading to

numerous individual terminal stations on a station-specific basis. The strain gauge was invented by Arthur Claude Ruge (1905–2000) and Edward E. Simmons Jr. (1911–2004) in 1938. Strain gauges have a very high duty cycle and can measure strain fluctuation in the order of several hundred kHz, also dependent on the size and thickness of the sensor material. There is usually a trade-off between the range of applied force that can be tolerated and the frequency response. A flexible strain gauge can be wrapped around a flexible tube to measure relative local pressure changes based on the radial EXPANSION. In order to enhance accuracy and avoid environmental influences two strain gauges can be matched in a WHEATSTONE BRIDGE type configuration, adjusting for optimal RESOLUTION on one strain gauge while the other is not subjected to change, other than environmental conditions, specifically temperature effects (see [Figure S.112](#)).

Figure S.112 Strain gauge. (Courtesy of www.doitpoms.ac.uk/; University of Cambridge, Cambridge, UK.)

Stratosphere

[energy, general, geophysics, thermodynamics] Atmospheric shell around the EARTH, the second layer of ATMOSPHERE on top of the TROPOSPHERE and below the MESOSPHERE. The stratosphere spans from an altitude at approximately 10–50 km, while the stratosphere above the poles starts at an altitude of 8 km and above the equator as high as 18 km. The stratosphere forms a protective layer from ULTRAVIOLET RADIATION due to the absorption of UVB and UVC in the formation of atomic (O) and diatomic oxygen (O₂) from ozone (O₃) in the outer edge of the stratosphere (stratopause), which are recombining in the mid-stratosphere to form ozone again. The recombination process releases ENERGY, which makes the middle stratosphere warmer than the lower stratosphere, which contributes to its stability. The outer edge of the stratosphere has a temperature just at 270 K $\cong$ -3°C , just below the FREEZING point of water. Commercial AIR traffic takes place in the lower stratosphere, 9–12 km altitude. Due to the lower density than the troposphere the air-drag for the planes is reduced, resulting in more fuel-efficient flight. In comparison, the Concorde would fly at 18 km altitude with velocity of Mach 2 (twice the speed of SOUND), and the Lockheed SR-71 blackbird spy plane would cruise at 26 km altitude at Mach 3. The stratosphere has various flow mechanisms. Horizontal MIXING is more prevalent than vertical mixing. One specific flow mechanism resulting from thermal and chemical gradients under the influence of GRAVITATIONAL WAVES is quasi-biennial OSCILLATION. Quasi-biennial oscillation is characteristic for the stratosphere and was discovered in the 1950s by meteorologists from Great Britain and has shown great influence on large weather patterns, such as the monsoon. In the quasi-biennial oscillation the quasiperiodic oscillation period in 28–29 months, yielding fluctuations in wind passage in the equatorial zonal alternating between eastward and westward. The alternating wind regimes originate in the upper level of the lower stratosphere and migrate downwards at about 1 km per month, where the propagation is subject to a damped oscillation, dissipating at the tropical tropopause. The downward propagation on the westward flow is usually more irregular than that of the westward flow. Hence the

AMPLITUDE of the easterly migration is about twice as large as that with respect to the westerly PHASE. The quasi-biennial oscillation has been confirmed by weather balloon observations (see Figure S.113).

Figure S.113 (a) Stratosphere. (Courtesy of Randy Russell, University Corporation for Atmospheric Research [UCAR], Copyright 2009, <http://scied.ucar.edu/imagecontent/stratosphere-diagram>.) and (b) Quasi-biennial oscillations in the pressure outline of the stratosphere. (Courtesy of The Freie Universität Berlin [Germany; Markus Kunze] supplies a QBO data set that comprises raw “insonde” observations from Canton Island, Gan, and Singapore based on the work of Naujokat, B. and Naujokat, B., 1986. An update of the observed quasi-biennial oscillation of the stratospheric winds over the tropics. *J. Atmos. Sci.*, 43, 1873–1877.)

Stream function

[fluid dynamics] A two-dimensional flow will originate in any arbitrary (but fixed) point (point A) and flow to a second point in the two-dimensional plane that is variable (point B) in its location. The FLUX between these two point can be represented by any line connecting point A and B, without leaving the boundary conditions (remaining with a confined area), without losing or gaining mass, represented by a stream function Ψ . The flow will adhere to the Navier-Stokes equation. For any point in the coordinate system (x, y) {“x” the abscissa for the coordinate of point A} there are velocities associated $u = -(1/\rho)(\partial\Psi/\partial y)$ and $v = +(1/\rho)(\partial\Psi/\partial x)$ (fluid density: ρ) that provide stream-lines that form an ANGLE (θ) with the normal to the curve (s) connecting A and B at any location δs , represented as $\theta' = \cos\theta$; $\theta'' = \sin\theta$. The flux is represented by the steam function as $\Psi = \int_A^B (\theta' u + \theta'' v) ds$. For IRROTATIONAL FLOW the following condition applies: $(\partial^2\Psi/\partial x^2) + (\partial^2\Psi/\partial y^2) = 0$. This is the Lagrange stream-function. In three-dimensional flow (coordinate system $[r, \phi, z]$) the flow function for incompressible, rotation free flow (axial symmetry) will adhere to $u_r = -(1/\rho)(\partial\Psi/\partial z)$, $v_z = +(1/\rho)(\partial\Psi/\partial r)$. From the stream function the streamlines can be

derived through: $\nabla \Psi \cdot \vec{n} = 0$. The streamlines provide a graphical interpretation of the flow by means of the density of the lines, and the cross-sectional area traversed. In practicality, the streamline represents the track followed by an individual PARTICLE, on average for a large number of particles (i.e., molecules).

Stress (σ_s)

[fluid dynamics, general, mechanics] Force (F) parallel to a cross-sectional area A resulting in the potential for deformation: $\sigma_s = F/A$. TENSILE STRESS describes the linear deformation, stretching or compressing, with forces acting along the line of action. Bulk stress is equivalent to pressure, imposing a change in volume. Shear stress represents two equal but opposing forces acting in parallel planes, providing angular deformation (*also see* SHEAR-STRESS) (see [Figure S.114](#)).

Figure S.114 The concept of Stress illustrated by vector diagram.

Stress birefringence

[general, optics] Stress applied to an optically transparent object will result in stress related changes in index-of-refraction, generating a focusing and DISPERSION, resulting in a COLOR pattern in response to the transmission of WHITE LIGHT. STRESS BIREFRINGENCE can be used for noninvasive quality control purposes. The stress may result from the structure of the device or as a result of an externally applied force (see [Figure S.115](#)).

Figure S.115 Stress birefringence. (Courtesy of Andrew Davidhazy.)

Strong nuclear force

[computational, energy, general, nuclear, quantum, relativistic, solid-state, thermodynamics] Short range strong force maintained by the elementary PARTICLE gluon. The range is approximately 1×10^{-15} m. The strong nuclear force is the strongest of the FOUR BASIC FORCES. The strong nuclear force acts on a property defined as “COLOR,” which has three states: r, g, b (also referenced as: red, green and blue). This in comparison with the electromagnetic forces that act on charges (positive and negative) and the gravitational force which acts on mass (see [Figure S.116](#)).

Figure S.116 Strong nuclear force interaction. The two opposing forces in a nucleus are (1) the electrical Coulomb repulsion between the positively charged protons and, respectively, (2) the residual strong nuclear force. The strong nuclear force provides the attraction between the protons and neutrons, specifically if the numbers of neutrons and respectively protons are not too much different in quantities, and hence overpowers the repulsive electrical forces.

Strouhal number ($Sr = vL / v_v$)

[biomedical, fluid dynamics] Dimensionless number in momentum transfer relating the inverse of the VORTEX SPACING, specifically for Von Kármán vortices and in UNSTEADY FLOW. The Strouhal number provides a classification of the ratio of forces resulting from acceleration under unsteady flow to the inertial forces from changing velocity (both magnitude and direction) in the turbulent flow pattern as a function of location. In the definition the following parameters are used: v_v : frequency of VORTEX SHEDDING (VORTEX SHEDDING FREQUENCY), L characteristic length and v the velocity of flow. The Strouhal number classifies and describes the characteristic phenomena of oscillating flow, such as pulsatile BLOOD flow. For most fluids both the flow frequency and velocity profile depend on the viscosity, more specifically the FLUID characteristics (e.g., pseudoplast, Newtonian, or dilatant fluid). A small Strouhal number ($Sr \ll 1$) correlates with a QUASI-STEADY STATE flow pattern, while high Strouhal numbers reference vortex shedding, the separation of a vortex flow pattern (at approximately $Sr = 0.2$).

Student's t-test

[biomedical, computational, solid-state] Statistical PROBABILITY distribution. The name “Student” was the pseudonym for W.S. Gosset, a quality control engineer with the Guinness beer brewery in Dublin, Ireland to hide his identity from the employers that were afraid of information about the processes leaking out. The publication in 1908 set the stage for all modern statistical analysis based on the distribution of the deviation from the mean value ($\bar{X}$) of a series of observations (n) described as $P_{\text{population}} = (\bar{X} - \mu_{\text{stat}}) / (s_{\text{variance}} / \sqrt{n})$, where $\mu_{\text{stat}} = \sum_{i=1}^n x_i P_{\text{stat}}(x_i)$ provides the weighed mean based on individual value (x_i) with respective probability of occurring ($P_{\text{stat}}(x_i)$) and $s_{\text{variance}}^2 = [1/(n-1)] \sum_{i=1}^n (x_i - \bar{x})^2$ is the standard deviation (also referred to as σ_s) of the variable x , with mean value $\bar{x}$. The t-test depends on whether the population distribution is a “NORMAL DISTRIBUTION.” The

distribution of the population of values ($P_{\text{population}}$) is evenly distributed around zero, or the mean value (depending on notation), with a “Gaussian shaped” slope that is a function of the number of DEGREES OF FREEDOM defining the variable x , described in the t -distribution as t_m , with m the number of degrees of freedom. The larger the number of degrees of freedom the closer the t -distribution approaches a Z -distribution.

Sturgeon, William (1783–1850)

[general] Scientist and inventor from Great Britain who developed the electromotor in 1832, based on the work of the early (static ELECTRICITY) work by the Scottish monk Andrew Gordon (1712–1751) in the 1740s. additional contributions came from the theoretical work by ANDRÉ-MARIE AMPÈRE (1775–1836) in 1820 and MICHAEL FARADAY (1791–1867) in 1821 (see [Figure S.117](#)).

Figure S.117 William Sturgeon (1783–1850).

Sturm, Jacques Charles François (1803–1855)

[computational] Mathematician from France. Jacques Sturm dedicated his work to solving complex integral equations and polynomials, specifically defining the roots of higher order polynomials (see [Figure S.118](#)).

Figure S.118 Jacques Charles François Sturm (1803–1855).

Sturm–Liouville technique

[computational] Standard procedure to solve certain types of differential equations by developing into eigenfunctions, with solutions containing eigenvalues. The Sturm–Liouville technique is a collaborative effort between JACQUES CHARLES FRANÇOIS STURM (1803–1855) and JOSEPH LIOUVILLE (1809–1882). The differential equation is expressed as an interaction between a set of functions (continuous functions: $f(x)$; $g(x)$; $b(x)$) with EIGENFUNCTION “SOLUTION” $y(x)$ outlined as $-(d/dx)[f(x)[\partial y(x)/\partial x]] + g(x)y(x) = c;b(x)y(x)$, with the boundary conditions specified through the

constant c_i , the eigenvalues ($c_1 < c_2 < c_3 < \dots < \infty$). The constraints on the eigenfunction is that it is continuously differentiable in the domain of the function. The function $b(x)$ defines the weight or NORMALIZATION.

Subatomic particles

[general] Particles that constitute the atomic model described by Bohr as well as the ELEMENTARY PARTICLES that form the atomic particles. Whereas atoms for the building blocks for MACROSCOPIC entities, ranging from LATTICE structures to molecules to objects. The objects form the components and dressing for planets and the atoms and molecules for the foundation of the nuclear reactions maintaining stars. In the opposite direction the ATOM is constructed from constituents that can be dissected in smaller and smaller entities. Atomic particles are electrons in the shells; respectively neutrons and protons in the NUCLEUS (nuclides). The atomic components are constructed from elementary PARTICLE we categorize as fermions and bosons. Fermions is a subgroup of what is known as elementary particles with odd spin ($1/2, 3/2, 5/2, \dots$), whereas BOSON have integer spin ($0, 1, 2, \dots$). These groups are further split in quarks and leptons. These subgroups are further subdivided in generations. The first generation of elementary particles are the ELECTRON (e^-), UP-QUARK (u), down quark (d) and electron-type NEUTRINO (ν_e). The second generation consists of MUON (μ), strange quark (s), CHARM quark (c) and muon-type neutrino (ν_μ). The third generation has top quark (t ; also known as truth) and bottom quark (b) next to the tau particle (τ) and tau-type neutrino (ν_τ). In addition all these first through third generation particles also have anti-particles, generally designated by a bar across the base symbol for the first order particle ($\bar{u}, \bar{d}, \bar{\nu}_e$, etc.), except for the positron; the anti-particle of the electron: e^+ . Hadrons are a family of particles that are constructed from quarks and antiquarks in a range of combinatory assemblies, presumably the PROTON the only stable HADRON in existence; accounting for their possible neutron DECAY (however in general the NEUTRON is also stable as NUCLIDE. Hadrons consist of subfamilies: baryons and mesons. For every hadron species there is an antiparticle. Baryons are MATTER particles, and mesons are designated as force particles. All baryons consist of three quarks, most well-known are the neutron and the proton in this class. Additional baryons are “Lambda-Zero” (Λ^0); “Omega Minus” (Ω^-); as well as permutations of Δ ; Ξ ; and Σ . Mesons are constructed of quark—anti-quark pairs only. So far no further delineation has been found for even smaller units that form the fermions and bosons, but this is currently mainly due to the equipment limitations required for verification. Some of the “elementary” particles were only theoretical assumptions dating back half a century and have only recently been provided with experimental support. (Note: The HIGGS BOSON [see QUARK, ELECTRON, and PROTON]) (see Figure S.119).

Figure S.119 Subatomic particle outline.

Sublimation

[general, thermodynamics] PHASE TRANSITION from solid to GAS. The terminology VAPOR is frequently used to identify a gas in equilibrium with its solid or LIQUID phase. The atomic or molecular ENERGY exceeds the BINDING ENERGY constraining them to their solid phase. Sublimation reduces the fraction of high-energy components in the solid, hence bringing the average kinetic energy down, thus reducing the overall temperature of the system, that is, cooling (see Figure S.120).

Figure S.120 Sublimation.

Subshell

[atomic, solid-state, thermodynamics] The BOHR ATOMIC MODEL is constructed in primary and secondary SHELLS. The primary shells are named in outgoing order as follows: K, L, M, N, O, P, and Q, corresponding with the PRINCIPAL QUANTUM NUMBER n , which is a positive integer and starts at $n = 1$ associated with the K-shell. The subshells are named: s, p, d, f, and g. The spins of the respective electrons is defined by HUNDS' RULE (sometimes also called HUND'S LAW). The s-subshell can hold two electrons, with respective opposite SPIN. The s-subshell has orbital quantum number (second quantum number, the first or principal quantum number n represents the) $\ell = 0$ and is present in every shell, with incremental numerator number: 1s for K-shell, 2s for L-shell, and so on. In the L-shell there are two subshells 2s and 2p, where the p-subshell is present in every shell outward from the second ordinal. The p-subshell has orbital or azimuthal quantum number, $\ell = 1$ and has the potential for containing six electrons (respectively two each for the third quantum number (i.e., MAGNETIC QUANTUM NUMBER) which defines the angular momentum, which ranges from $m_\ell = [-\ell, -\ell + 1, \dots, 0, \dots, \ell - 1, \ell]$, or $2\ell + 1$ possible states, yielding: $m_\ell = -1$, $m_\ell = 0$, $m_\ell = 1$). In the Bohr atomic model the f-subshell may contain a total of 7 pairs of electrons, 14 total and the f-subshell appears in the N-shell for the first time. One can illustrate the configuration of the shell/subshell arrangement with the appropriate ENERGY nomenclatures in tabular format.

Sun

[astrophysics, atomic, general, geophysics, nuclear, optics, quantum] STAR central to our own SOLAR SYSTEM. Hydrogen NUCLEAR FUSION reactor producing a broad spectrum of particulate and electromagnetic RADIATION, and emitting on average $63 \times 10^6 \text{ W/m}^2$. Of which only approximately $1.2 \times 10^3 \text{ W/m}^2$ reaches EARTH on perpendicular incidence. Note that the global radiance fluctuations are a function of the location on Earth (ANGLE of incidence), time of day and the seasonal DISTANCE to the Sun (r^{-2} dependance). The average distance from the Sun to Earth is $1.496 \times 10^{11} \text{ m}$. The average surface temperature of the Sun is 5778 K. The mass of the Sun is in approximation $M_\odot = 1.989 \times 10^{30} \text{ kg}$, containing greater than 99.8% of the total mass for our solar system of Sun and planets (JUPITER containing a significant total mass as second largest object), with solar radius $R_\odot = 6.958 \times 10^8 \text{ m}$. The Sun and associated solar system including Earth are close to the outer edge of the MILKY WAY galaxy and we all orbit the center of the Milky Way galaxy.

Sunlight takes on average 8.3 min to reach Earth, traveling at the speed of LIGHT. The FUSION process in the PLASMA of the Sun proceeds as follows. The first to steps are the fusion of hydrogen; proton fusion (${}^1_1\text{H}$) with the release of a positron (e^+) and electron NEUTRINO (ν_e): ${}^1_1\text{H} + {}^1_1\text{H} \rightarrow {}^2_1\text{H} + e^+ + \nu_e$, followed by step two ${}^1_1\text{H} + {}^2_1\text{H} \rightarrow {}^3_2\text{He} + \gamma$, emitting high ENERGY gamma radiation (γ) and deuterium (${}^2_1\text{H}$). There are a number of possibilities for the third stage fusion process, the dominate process: ${}^3_2\text{He} + {}^3_2\text{He} \rightarrow {}^4_2\text{He} + {}^1_1\text{H} + {}^1_1\text{H}$, forming helium. All three process produce approximately $27\text{ MeV} = 4.326 \times 10^{-12}\text{ J}$. The outlines of this process was first described by the German nuclear physicist HANS ALBRECHT BETHE (1906–2005) in 1939, for which he was awarded the Nobel Prize in Physics in 1967. The work of Hans Bethe was based on the initial conceptual description by the British physicist Sir ARTHUR STANLEY EDDINGTON (1882–1944) in 1920. The Sun holds the planets in the solar system, with respective mass m , in orbit by means of gravitational attraction as a function of distance (r) as defined by SIR ISAAC NEWTON's (1642–1727) LAW OF UNIVERSAL GRAVITATION: $F = G(mM_{\odot}/r^2)$, with $G = 6.67 \times 10^{-11}\text{ Nm}^2/\text{kg}^2$ the gravitational constant. The Sun frequently ejects plasma jets known as solar flares, which are accompanied by intense RADIO frequency emissions that influence the wireless communications on Earth (see [Figure S.121](#)).

Figure S.121 Sun.

Sun spot

[geophysics, optics] Disturbances in the Sun's convection currents. Sun spots have an apparent 11 year cycle, first observed by GALILEO GALILEI (1564–1642) in 1610. Sun spots are associated with a MAGNETIC FIELD in the order of 1kG (compared to BAR MAGNET $B = 100\text{ G}$) (see [Figure S.122](#)).

Figure S.122 Sun spots.

Sundog

[geophysics, optics] Atmospheric phenomena that form “mirror” images of the SUN on either side of the Sun in the sky, also referred to as parhelia, frequently coinciding with a halo. The mock suns are the result of atmospheric diffraction due to pressure layers and thermal gradients. The primary aspect of sundogs is in the refraction from ice crystals. In case the Sundogs are formed in pairs they will be at approximately 22° angle from the Sun from the point of the observer (*also see* RAINBOW) (see Figure S.123).

Figure S.123 Sundog.

Superconducting quantum interference device (SQUID)

[general] Superconductive MAGNETIC FIELD sensing device. SQUIDS are used to measure minute magnetic fields, such as produced by the brain, with RESOLUTION and sensitivity down to 10^{-18} T. In comparison, the magnetic field at the surface of an atomic NUCLEUS: 10^{12} T; hair dryer in close proximity 10^{-3} T; small BAR MAGNET near the poles 10^{-2} T; and the geomagnetic field at the earth's surface 10^{-12} T. Squids are miniature superconductive current loop devices developed by the team at the Ford Research Laboratories (part of the Ford Motor Company; Dearborn, MI, USA) consisting of Robert C. Jaklevic (mid-twentieth century–), John J. Lambe (mid-twentieth century–), James Mercereau (mid-twentieth century–), and Arnold Silver (mid-twentieth century–) in 1964. The squid mechanism-of-action is based on the Josephson Effect defined

by the theoretical physicist from the United Kingdom (Wales), BRIAN DAVID JOSEPHSON (1940–) in 1962. The sensitivity is based on the measured current which is a function of the magnetic FLUX passing through the SQUID loop with diameter d and under applied magnetic field strength B , under constraints: $I_c^2 = (I_{c1} - I_{c2})^2 + 4I_{c1}I_{c2} \cos^2(\pi d^2 B / (b/2e))$, where the current is split in the half circumferential proportions I_{c1} , respectively I_{c2} , where $b = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK'S CONSTANT (see Figure S.124).

Figure S.124 SQUID design.

Superconductivity

[atomic, energy, solid-state] The fact that materials lose all electrical BARRIERS and have impedance of zero at cryogenic temperatures. The work of KAMERLINGH ONNES (1853–1926) revealed the first signs of superconductivity in 1911.

Supercritical fluid state

[thermodynamics] Specific phenomenological state/phase of a liquid or GAS that is only available above the CRITICAL POINT, explained best in the P–T DIAGRAM (pressure vs. temperature). For water the critical point is defined by $P = 218.3 \text{ atm}$, $T = 374.15^\circ\text{C}$, at this point the FLUID is a supercritical fluid with density $\rho = 0.315 \text{ g/mL}$. In comparison the respective characteristics of gas, liquid and supercritical state are exemplified in the table in order of MAGNITUDE respectively.

STATE	DENSITY (kg/m³)	DIFFUSIVITY (cm²/s)	VISCOSITY (kg/ms)
Supercritical	200–900	10 ^{−4}	10 ^{−3}
Gas	1	10 ^{−1}	10 ^{−3}
Liquid	1000	10 ^{−4}	10 ^{−1}

The supercritical state is identified by conditions of compressibility, which for a LIQUID would under normal circumstances be not allowed, meanwhile the supercritical fluid has the density of a liquid under standard pressure and temperature. The supercritical fluid does neither behave as a liquid nor as a gas, but has characteristics of both and is a new PHASE or state-of-matter.

Supercritical mass

[general] A threshold mass of ISOTOPE material beyond which the material spontaneously fuses, the fissionable material spontaneously initiates a CHAIN REACTION. The most well-known critical mass is the FUSION of URANIUM (enriched) (^{235}U) to produce an extraordinary amount of ENERGY when two segments of approximately half the critical mass are forcefully joined (by means of an explosion) to result in an increase in volume that its surface area, producing a perceived surplus of emitted neutrons causing the DECAY reaction to escalate, resulting in a thermo-nuclear explosion at 52 kg. Other critical mass data for specific ELEMENTS are $^{233}\text{U} \rightarrow 15 \text{ kg}$; $^{236}\text{Pu} \rightarrow 9.04\text{--}10.07 \text{ kg}$ (range); $^{236}\text{Np} \rightarrow 7 \text{ kg}$; and $^{252}\text{Cf} \rightarrow 2.73 \text{ kg}$.

Superfluid

[atomic, nuclear] Extraordinary PHASE of a medium, not GAS, not LIQUID, not solid, which behaves with viscosity $\eta_{\text{kin}} = 0$. The superfluid has entropy $S = 0$, and all atoms are in the same QUANTUM STATE, with identical momentum. The best known example of a superfluid state is Helium, which becomes a superfluid with decreasing temperature at 2.18 K. Superfluid Helium is the most remarkable heat CONDUCTOR (virtually perfect conduction), while remaining electrically neutral, that is, an INSULATOR.

Superheated steam

[general, thermodynamics] Water VAPOR at temperature above 100°C at 1 atmosphere pressure.

Superheated vapor state

[thermodynamics] Evaporated state of a LIQUID at temperature above the vaporization temperature.

Supernova

[astronomy/astrophysics, energy, general] The classification of the end-stage of a STAR, culminating in an explosion and associated massive emission of NEUTRON, photons, neutrinos and variety of charged particles and electromagnetic RADIATION in massive quantities. On EARTH the NEUTRINO and PHOTON emission from an exploding supernova (SN 1987A) in the Tarantula Nebula (also known as the “star-forming region” 30 Doradus or NGC 2070) in the Southern hemispherical orientation for the general direction of the GALAXY: Large Magellanic Cloud (LMC) in the Dorado constellation; at 168,000 light-years DISTANCE from Earth reached the underground detection stations in Cleveland, Ohio, and Tokyo, Japan, in 1987. The emissions from Supernova 1987A, called for the first observation, are still being observed (see [Figure S.125](#)).

Figure S.125 Supernova.

Supersonic flow

[fluid dynamics] Flow conditions with propagation velocity greater than the speed of SOUND. Supersonic flow results in a dramatic cooling effect, for instance accelerating from rest at room temperature ($25^{\circ}\text{C} = 298\text{ K}$) to Mach 3 will reduce the temperature of the FLUID to $-166^{\circ}\text{C} = 107\text{ K}$. Alternatively an object traveling at Mach 3 will increase its surface temperature due to FRICTION to $530^{\circ}\text{C} \approx 800\text{ K}$. Supersonic flow can be achieved through SHOCK-WAVE formation (see Figure S.126).

Figure S.126 Supersonic flow. (a) Supersonic aircraft carrier: Concorde (discontinued air transport plane) and (b) computer flow simulation, false-color indication of stream flow velocity.

Surface charge density (σ_{elec})

[general] Charge density on the surface of a CONDUCTOR, evenly spread, defined by the total charge Q on the object, divided by the surface area A : $\sigma_{\text{elec}} = Q/A$. For a nonconductive medium the local charge density will be location specific since there is no free migration of charge. The charge surface density on a curved surface for a conductor will be a function of the radius of curvature, with greater charge density with smaller radius of curvature: $\sigma_{\text{elec},r}/\sigma_{\text{elec},R} = R/r$, where R denotes the large radius of curvature (such as defining the outline for the body of a rounded cone) and r the radius of curvature of the pointy tip (see Figure S.127).

Figure S.127 Surface charge density.

Surface energy

[chemical, fluid dynamics, mechanics, thermodynamics] ENERGY aspect of SURFACE TENSION. The work performed by the force that creates the new surface area. Materials have specific surface energy, for instance the surface energy for the following solids is as follows: KCl has a surface energy of $E'_s = 0.11\text{ J/m}^2$, glass

(BK7) $E'_s = 4.4 \text{ J/m}^2$, mica in VACUUM $E'_s = 5.0 \text{ J/m}^2$, whereas mica in AIR has $E'_s = 0.38 \text{ J/m}^2$, granite has $E'_s = 200 \text{ J/m}^2$. Contamination of the substance will reduce the surface energy. Surface energy is an important factor in crack formation for a solid, but also defines the BUBBLE formation for a VAPOR bubble from a LIQUID or solid.

Surface gravitational wave

[acoustics, fluid dynamics, geophysics, mechanics] WAVE on the surface of a fluid (LIQUID or GAS) that are influenced by gravitational restoring forces. Surface GRAVITATIONAL WAVES are described as Lamb waves on the surface of an AIR mass, or the “surf” on the water of oceans and lakes, in particular breaking on the shore of a landmass (see WAVE or SURFACE WAVE). On a QUANTUM mechanical level the other concept of gravitational wave relates to transverse wave of massless quantum PARTICLE. The concept of quantum-mechanical gravitational waves is directly linked to the ALBERT EINSTEIN’s (1879–1955) principle of general relativity (see Figure S.128).

Figure S.128 Surface gravitational wave.

Surface phenomena of Liquids

[chemical, fluid dynamics, mechanics, thermodynamics] A LIQUID is a continuous medium with minimally one surface (spherical symmetry), the surface is exposed to forces and ENERGY constraints. Within a medium similar phenomena can occur in the form of BUBBLE, also only one continuous surface. In a container the walls of the container define the number of surfaces and one surface may be exposed to GAS (i.e., AIR or liquid vapor). At any surface the LIQUID will have stress and strain expressed by one of the phenomena: SURFACE TENSION.

Surface Potential Energy

[biomedical, chemical, computational, fluid dynamics, mechanics, thermodynamics] Theoretical model of the ENERGY configuration of a system, specifically atoms with respect to their arrangement. The concept is used primarily in computational chemistry. The surface potential energy, also known as potential energy surface, defines the relationship between the energy configuration of a MOLECULE and the geometry of the molecule, either in graphical format or mathematically. The graphical representation for instance represents the potential energy for a molecule as a function of the bond-length and the ANGLE of the atomic bond. In molecular MECHANICS the potential surface energy described the molecular energy with respect to bending, TORSION, stretching, and so on. Under QUANTUM mechanical approach the energy function outlines the work effort with respect to the SCHRÖDINGER WAVE EQUATION. The two-dimensional energy surface can illustrate the atomic configuration (bond length and bond angle) that is more susceptible to chemical interaction: transition state. This model does not account for the inherent incessant vibrations of the molecule, neither for deviations from equilibrium. Under equilibrium conditions the SCHRÖDINGER EQUATION for the molecule can be solved by assuming a simple HARMONIC OSCILLATION (with spring constant k) around equilibrium (interatomic equilibrium DISTANCE $\vec{q}_e$) in the direction of the connecting line of the interatomic bond links ($\vec{q}$); using $E = (1/2)k(\vec{q} - \vec{q}_e)^2$. This potential

energy is however not valid when the atomic separation is far from equilibrium length. The potential energy levels off, drops off, with increasing separation on the bond-length. In QUANTUM MECHANICS the molecular Hamiltonian is defined by the ATOMIC NUMBER (Z) and respective distances between nuclei (R_{12} [fixed]; r_{1i} ; r_{ij} , electron orbits: i, j) within the molecular structure and respective molecular constituents (i ; 2 ; mass m_i) as $\hat{H} = -(1/2)\sum_i \nabla_i^2 - \sum_i (1/2m_i)\nabla_i^2 - \sum_{1,i} (Z_1/r_{1i}) + \sum_{1>2} (Z_1Z_2/R_{12}) + \sum_{i>j} (1/r_{ij})$, where the term $V_{eN}(\vec{r}, \vec{R}) = -\sum_{1,i} Z_1/r_{1i}$ represents the electron (e) nuclear potential energy (N DEGREES OF FREEDOM). The SURFACE ENERGY potential prevents the Hamiltonian from being separated. Without surface potential energy the Hamiltonian is separable with energy eigenvalues: $E = E_A + E_B$, and eigenfunctions: $\Psi(q_1, q_2) = \Psi_A(q_1)\Psi_B(q_2)$; $\hat{H}_A(q_1)\Psi_A(q_1) = E_A\Psi_A(q_1)$, and $\hat{H}_B(q_2)\Psi_B(q_2) = E_B\Psi_B(q_2)$. The electron–nuclear potential inherently ties the electronic degrees of freedom to the nuclear degrees of freedom. The potential energy surface applies to the molecular dimension (R) as $\hat{H}_e(\vec{r}; \vec{R})\Psi(\vec{r}; \vec{R}) = E_e(\vec{R})\Psi(\vec{r}; \vec{R})$ (also see BORN–OPPENHEIMER APPROXIMATION) (see Figure S.129).

Figure S.129 Graphical representation of Surface potential Energy.

Surface roughness

[acoustics, fluid dynamics, mechanics] Unevenness in the profile of a system, either object, channel (river) or PIPE. The ROUGHNESS defines the absolute or relative deviations from ideally smooth for a segment or with respect to the attainable effects resulting from a surface treatment or construction technique, next to the choice of material (e.g., ceramics vs. wood vs. metal). Commonly used surface parameters are: roughness area $R_a = 1/n \sum_{i=1}^n |z_i|$ (z_i the localized deviation from perfect flat, measured in n locations); root-mean-squared roughness $R_q = \sqrt{(1/n \sum_{i=1}^n z_i^2)}$; or with respect to the maximum allowable height of the imperfections. More detailed, in three dimensions: $R_a = 1/mn \sum_{k=0}^{m-1} \sum_{\ell=0}^{n-1} |z(x_k, y_\ell) - \mu_{ave}|$, $\mu_{ave} = 1/mn \sum_{k=0}^{m-1} \sum_{\ell=0}^{n-1} z(x_k, y_\ell)$ representing the preferred level (e.g., radius) or average. Additional parameters used in defining the surface profile, as for instance used in design drawings (CAD drawings) is the slope of the unevenness by means of deviation from level under ANGLE α : $R_{dq} = \sqrt{(1/n \sum_{i=1}^n \alpha_i^2)}$ or $R_{da} = 1/n \sum_{i=1}^n |\alpha_i|$. The angular deviations are determined from surface elevation iterations. One standard compares unevenness as a function of linear location x as $\alpha_i = 1/60 dx (z_{i+3} - 9z_{i+2} + 45z_{i+1} - 45z_{i-1} + 9z_{i-2} - z_{i-3})$, around flat z_i . The latter would apply to machining instructions such as turning a rod on a lathe. These parameters are set under industry standards implemented by professional organizations such as American Society of Mechanical Engineers (ASME) or ISO STANDARDS (International Organization for Standardization). Surface finish contributes to the FRICTION between two surfaces as well as the influence on the formation of BOUNDARY LAYER effects during flow. The three-dimensional configuration of a surface can be examined by atomic force microscopy, Optical interference profilometry scanning (e.g., OPTICAL COHERENCE TOMOGRAPHY) or Scanning Electron

Microscope on MICROSCOPIC level, or by surveying tools on MACROSCOPIC scale. Controlling the roughness can result in expensive processes, increasing the final price/cost for the device. In general during design the surface roughness is specified with acceptable tolerance for the specific goal of the use of the material, device or structure. Optical devices are specified in surface treatment with respect to the wavelength (λ), not more deviation than a fraction of the average or standard wavelength. Also referred to as roughness. May also be described as surface texture (see [Figure S.130](#)).

Figure S.130 (a–f) Surface roughness.

Surface tension

[biomedical, chemical, fluid mechanics, mechanics, thermodynamics] Stress in the SURFACE of a LIQUID, equivalent to the WORK (i.e., force $[F]$ multiplied by displacement $d\ell$ given as $W = Fd\ell$) per unit area to change the size of the area (dA) (increase, work performed by decrease; most liquids at most TEMPERATURE ranges): $\sigma_{\text{surface}} = Fd\ell/dA$. For a cord or rod confining a soap film the area can for instance be expressed as $dA = 2Ld\ell$, since the demarcation between the film and outside has a length on both sides of the BARRIER. Physical equivalence in a SKIN stretched over a hoop, for instance for a musical drum. A surface layer may be on a continuous medium or film (e.g., soap BUBBLE). Surface tension is generally independent of the layer thickness, reducing the effect to a molecular phenomenon (i.e., VAN DER WAALS FORCE). Surface tension on a droplet will confine a medium by force, hence the pressure (VAPOR PRESSURE) inside the droplet will always be greater than the outside pressure. The surface tension on a single surface medium is defined by the LAPLACE LAW. One specific exception to the single surface is in the ALVEOLI of the LUNG. Another surface tension phenomenon is in the boundary between a vessel and the surface of a liquid. Liquids may adhere to the vessel surface ("wet the surface of the container") or be repelled by the container WALL ("liquid does not wet the surface"). When the liquid ADHESION (i.e., COHESION) is strong the liquid will form a negative meniscus, in case the adhesion to the vessel is stronger than the cohesion of the liquid the liquid will form a positive meniscus. One specific example is water in a glass beaker. Since glass is polar it will tend to attract the polar water molecules applying grease to the wall of the beaker will separate the polar attraction by the GLASS from the cohesive Vander Waals force and the MENISCUS will flip negative. A positive meniscus is often an indication that there is potential for the liquid to actively CREEP up the wall. The creep is especially noticeable in a narrow tube, creating CAPILLARY ACTION, making the liquid climb the wall of the tube for a considerable DISTANCE, depending on the tube diameter and the density of the liquid. Contact ANGLES for some interfaces vary as a function of temperature. Wetting liquids on a clean surface (i.e., water on glass) will continue to spread until the water has reached molecular thickness (i.e., MONOLAYER). Surface tension can be broken by means of chemical binding (dissolve the chemical based on the match in polar nature, whereas OIL is very nonpolar) with a SURFACTANT, such as ordinary soap (see Figure S.131).

Figure S.131 Surface tension: tension between liquid and solid surface of container.

Most organic liquids—glass	0°–10°
Mercury—copper	0°
Pure water—glass	0°
Water—glass	20°
Kerosene—glass	26°
Water—silver	90°
Water—parafin	106°
Mercury—glass	148°

Surface waves

[fluid dynamics] Waves on the surface of a medium (primarily liquid, alternative approach for solids) generated from equilibrium (*also see* WAVE EQUATION, for general theoretical description of periodic motion). Surface waves can result from wind blowing over the waver surface, or as a result of EARTHQUAKE (i.e., TSUNAMI). This phenomenon is governed by the CONSERVATION LAWS in the form of the Euler equations for a medium with constant density: $\rho = \rho_0$. The VELOCITY POTENTIAL (ϕ) for a two-dimensional plane-wave with displacement in the y -direction, propagating in the x -direction will be irrotational and satisfies the condition: $(\partial\phi^2/\partial x^2) + (\partial\phi^2/\partial y^2) = 0$, with the condition $\partial\phi/\partial n = 0$. This is described by the Cauchy-Poisson wave equation. The vertical displacement (i.e., MOTION around equilibrium level) as a function of linear direction of propagation is given as $b(x, t) = 1/\pi x \{ (gt^2/2x) - (1/3 \times 5)(gt^2/2x)^3 + (1/3 \times 5 \times 7)(gt^2/2x)^5 - \dots \}; (gt^2/2x) \ll 1$, with a constant acceleration of the PHASE of the WAVE given as $a_{pb} = (g\pi A_w/\lambda) [\cosh(2\pi^{b_a+b(x,t)/\lambda})] / [\cosh(2\pi^{b_a/\lambda})] \sin((2\pi x/\lambda) - (2\pi t/T))$, where g the GRAVITATIONAL ACCELERATION, A_w is the wave AMPLITUDE, b_a is the average depth of the water or the average DISTANCE from the solid bottom to the surface of the FLUID in motion, T the wave period and λ the wavelength. Generally, for a small displacement the surface motion can be described by a FOURIER SERIES as a sine and cosine sum (*see* WAVE EQUATION). The surface wave propagation in fact stretches the wave pattern out as it propagates with wavelength: $\lambda = 8\pi s^2/gt^2$ with t the elapsed time. The surface-wave itself propagates with the group velocity: $v_g = 0.5c(1 + (2kb_a/\sinh 2kb_a))$, where $c = \sqrt{(g/k)\tanh kb_a} \cong \text{Constant}$, at constant depth (b_a , the average surface height from the seafloor), and $k = 2\pi/\lambda$ is the wavenumber. Note that for example, the wave breaking on the surface is the result of a nonlinearity in the acceleration, the DISPERSION in this case is the direct result of a difference in linear acceleration on the surface as a function of both wavelength and depth defined by $a = dv_g/dt$. Alternatively: $b(s, t) \cong \sqrt{g} t^2/\rho 2^{5/2} \pi^{1/2} s^{5/2} \{ \cos(gt^2/4s) - \sin(gt^2/4s) \}; (gt^2/2s) \geq 1$, where s is the path of propagation. The PHASE VELOCITY of surface waves is gives as $v_{pb} = \sqrt{((g\lambda/2\pi) + (2\pi T_s/\rho\lambda)) \tanh(2\pi b_a/\lambda)}$, where T_s is the LIQUID surface tension, ρ the liquid density. (p36 Fundamentele Natuurkunde, deel 3 Golven; Alonso & Finn//Fundamental University Physics #3.) Since the phase velocity is apparently a function of the wavelength a phenomenon known as WAVE DISPERSION will occur. Under dispersion the complex wave constructed of the superposition of multiple waves with a range of frequencies will deform in the process of propagation in the dispersive medium. The deformation results from the different velocities of the respective spectral components of the complex wave. The phase velocity of surface waves can be derived under condition that the wave amplitude is sufficiently small using linear theory providing for deep water: $v_{pb} = \sqrt{(g/k)}$; $b(s, t) > 0.4\lambda$, and for shallow water: $v_{pb} = \sqrt{((g\lambda/2\pi)(2\pi b/\lambda))} = \sqrt{gb}$; $b(s, t) < 0.04\lambda$ (*see* Figure S.132).

Figure S.132 Surface wave resulting from earthquake causing destruction due to vibration.

Surfaces of discontinuity

[fluid dynamics] See DISCONTINUOUS MOTIONS.

Surfactant

[biomedical, chemical, fluid mechanics, mechanics, thermodynamics] Chemical medium that has as property to lower the SURFACE TENSION of a FLUID when mixed or applied to the surface. Soap/detergents is a surfactant, designed to modify the tension between two media, for example, lowering the ADHESION of loose material from a solid (e.g., food on plate; dirt on clothing). Wettings agents and detergents generally have a molecular structure that is hydrophobic on one side and hydrophilic on the opposite side (amphiphilic). A surfactant may also be designed to have a nonlinear relation to the surface area (specifically applied to spherical configuration), defying the LAPLACE LAW. In the lungs the surfactant on the inside of the alveoli is specifically that way, made of six lipids and four proteins, adjusting to the size of the alveoli for optimal oxygen transfer between the AIR in the lung and the CELL layer. Lung surfactant is produced between week 24 and 28 of gestation. Premature babies (prior to week 35) often require surfactant replacement therapy to ensure proper VENTILATION of oxygen and carbon-dioxide. Lung surfactant can be produced artificially under synthetic circumstances (see [Figure S.133](#)).

Figure S.133 Surface forces diagram.

Synapse

[biomedical, chemical] Chemical transponder between nerve CELL (at the terminal end of an axon or dendrite) that releases chemicals upon excitation by an action potential. The release of the specific chemicals are correlated to the function and location of the nerve-cell and are a chemical mediator to induce a chemical imbalance at the synapse across from the junction that will lead to a trans-membrane potential resulting in the initiation of an action-potential in the next link of SIGNAL transport to reach the final destination,

either MUSCLE, brain or specific chemical organ (e.g., digestive or regulatory in the form of BLOOD acidity) (See NERVE) (see [Figure S.134](#)).

Figure S.134 Synapse.

Synaptic signaling

[biomedical, chemical, energy] Secretion of signaling molecules (i.e., NEUROTRANSMITTERS) between neurons. The chemical exchange initiates an ACTION POTENTIAL in all the neurons connecting at the “router-station.” Signals can be amplified in this manner by exciting multiple neurons and hence increasing the communication channels to one or multiple terminal locations in the sympathetic and PARASYMPATHETIC NERVE SYSTEM as well as the brain and brain-stem (see [Figure S.135](#)).

Figure S.135 Synaptic signaling.

Synchrotron

[astronomy/astrophysics, atomic, energy, nuclear] **Linear PARTICLE ACCELERATOR**. The largest linear accelerator is at the European Organization for Nuclear Research; CERN facility ("Conseil Européen pour la Recherche Nucléaire" French) at the border between Switzerland and France. The CERN SYNCHROTRON can reach kinetic energies for protons in excess of 10^3 GeV, simultaneously for in the order of 10^{13} protons (see [Figure S.136](#)).

Figure S.136 Synchrotron. (Courtesy of Fermi National Accelerator Laboratory [Fermilab], Batavia, IL.)

Synchrotron radiation

[astronomy/astrophysics, atomic, energy, nuclear] **RADIATION** emitted by a charged **PARTICLE** when accelerated around a curved path, change in direction. In comparison, every charged particle under linear acceleration will emit electromagnetic radiation.

Systolic pressure

[biomedical] Pressure achieved by the full contraction of the **HEART**. The maximum pressure applied to **BLOOD** ejection into the compliant vascular system of the biological body. High level pressure is measured by the **SPHYGMOMANOMETER**. The auscultation technique involves wrapping an inflatable cuff around the elbow of the arm and inflating the external pressure above any reasonably known high systolic pressure, and subsequently systematically reducing the applied pressure to balance with the pressure in the tissue applied to the brachial artery in order to listen for the **KOROTKOFF SOUNDS**. In combination with the **DIASTOLIC PRESSURE** these are some of the vital signs acquired during a routine visit to the doctor's office, next to heart-rate and body temperature. The aortic pressure fluctuates between the systolic and the diastolic pressure with each heartbeat. In case any of these show deviations from the norm additional diagnostic techniques may involve obtaining an **ELECTROCARDIOGRAM (ECG)**, next to further analysis of the respiratory system with breathing exercises. A variety of physical and psychological reasons can result primarily in a change in systolic, and secondary in diastolic, pressure. One of the most common causes for **BLOOD PRESSURE** variability is general

heart disease, followed in second place by reduction in vascular COMPLIANCE or respectively an increase in RESISTANCE for the down-stream fluid-dynamics system (the CIRCULATION) (see [Figure S.137](#)).

Figure S.137 Systolic pressure of the human heart obtained during contraction, facilitating pumping action.

Taylor & Francis

Taylor & Francis Group

<http://taylorandfrancis.com>

't Hooft, Gerard {Geradus} (1946–)

[atomic, general, solid-state] Scientist from the Netherlands. 't Hooft made his first contribution as a graduate student in 1969 on the Yang–Mills gauge fields, showing how they could be renormalizable; thus formulating the concept of renormalization (see [Figure T.1](#)).

Figure T.1 Gerard 't Hooft (1946–).

Tachyon

[general, quantum, relativistic] Hypothetical massless PARTICLE that moves at velocities greater than the speed of LIGHT. In current theoretical context, a velocity faster than the speed of light under special relativistic doctrines will violate the causality principles. The tachyon concept was introduced by Olexa-Myron Bilaniuk (1926–2009), VIJAY DESHPANDE (mid-twentieth century–), and George Sudarshan (1931–) in 1962. In this assumption, the ENERGY is thought of as imaginary, avoiding the relativistic rest-mass constraints: $E^2 = p^2 c^2 + m^2 c^2$, where $p = mv$ the momentum, v the velocity, m the mass, and $c = \sqrt{\mu_0 \epsilon_0}^{-1} = (\mu_0 \epsilon_0)^{-1/2} = 2.99792458 \times 10^8$ m/s the speed of light.

Tacoma Narrows Bridge

[general] Infamous bridge in the Washington state of the United States that had a design of suspension cables. The bridge spanned across the Tacoma Narrows strait of Puget SOUND. The suspension cables were subject to wind blowing in from the Pacific Ocean. Under specific conditions, the wind was able to bring the cables into

VIBRATION. At one time, the vibrations of the cables matched the RESONANCE vibration frequency of the main bridge, causing the entire bridge to oscillate, eventually leading to mechanical failure in 1940. The failure occurred only months after the completion of the bridge's construction (*also see* RESONANCE) (see [Figure T.2](#)).

Figure T.2 Tacoma Narrows Bridge under oscillation resulting from the Aeolian sounds generated by the wind stroking the suspension cables.

Tait, Peter Guthrie (1831–1901)

[general] Scientist from Scotland, Great Britain, contemporary and colleague of LORD KELVIN (1824–1907), WILLIAM HAMILTON (1805–1865), and JAMES CLERK MAXWELL (1831–1879). The work of Guthrie Tait focused on general PHYSICS, and he introduced several mathematical treatments and definitions for general physics concepts, specifically MECHANICS (see [Figure T.3](#)).

Figure T.3 Peter Guthrie Tait (1831–1901).

Tangential acceleration (a_T)

[general, mechanics] Acceleration associated with the revolution of an object and the associated change of angular velocity (direction and MAGNITUDE): $\alpha_c = a_T / r$, with a_T the tangential acceleration, r the radius from the center of the revolution, and the centripetal acceleration, changing the tangential ANGULAR VELOCITY (ω) as a function of time (t): $\alpha_c = d\omega/dt = d^2\theta/dt^2$, θ the ANGLE of rotation. The tangential acceleration forms a counterforce to maintain circular MOTION (see Figure T.4).

Figure T.4 Tangential acceleration, changing the direction of the constant velocity of revolution.

Tangential stress

[fluid dynamics, mechanics] Angular or circumferential STRESS (stress holding the shear for the potentially expanding “shell of the medium.” In contrast to shear stress that is parallel to the plane of the material CROSS SECTION. Alternatively, normal stress is applied perpendicular to the material cross section. In tubes there are generally three stresses to be considered: longitudinal stress, radial stress, and hoop or tangential stress. Hoop stress is a tangential stress, in the circumferential direction. The hoop stress, specifically for a thick-walled tube, at any location r within the WALL of the tube with an inner radius r_i , outer radius r_o , wall thickness $d = r_o - r_i$ is $\sigma_{c, \text{thick}} = [(P_i r_i^2 - P_o r_o^2) / (r_o^2 - r_i^2)] - [r_i^2 r_o^2 (P_o - P_i) / r^2 (r_o^2 - r_i^2)]$. Alternatively for a

thin-walled tube (e.g., balloon; “holding the balloon together”) the tangential stress is $\sigma_{e,\text{thin}} = P_i r_i / d$, also known as SHEAR STRESS (see Figure T.5).

Figure T.5 (a–c) Tangential stress, for instance on blood vessel. (a,b: Courtesy of Dr. Romesh Batra; Virginia Polytechnic Institute, Blacksburg, Virginia.) (c: Courtesy of Häggström, Mikael. “Medical gallery of Mikael Häggström 2014.”)

Tate, John Torrence, Jr. (1925–)

[chemical, general, mechanics] Scientist and mathematician from the United States. Tate provided a wealth of information with regard to tension, specifically SURFACE TENSION, and THERMODYNAMICS (see [Figure T.6](#)).

Figure T.6 John Torrence Tate, Jr. (1925–), photograph by George M. Bergman.

Tate, John Torrence, Sr. (1889–1950)

[general, mechanics] Physicist from the United States, father of JOHN TORRENCE TATE, JR. (1925–) (see [Figure T.7](#)).

Figure T.7 John Torrence Tate, Sr. (1889–1950).

Tate's law

[general, mechanics] Boundary condition in droplet formation, for a LIQUID with mass m_{liq} , subject to a SURFACE TENSION (as may be described by the Marangoni surface tension T_s) the droplet will detach from the stream when the surface curvature reached $\chi = 90^\circ$, or that the droplet confinement needs to satisfy: $m_{\text{liq}}g \leq 2\pi r_{\text{stream}} T_s \sin \chi$, which yields $m_{\text{liq}}g = 2\pi r_{\text{stream}} T_s$, where r_{stream} is the radius of the FLUID stream, or the radius of a CAPILLARY tube, and g the GRAVITATIONAL ACCELERATION. As defined in 1864 by JOHN TORRENCE TATE, SR. (1889–1950) and applied in the stalagmometer device to measure surface tension, T . Tate introduced this equation to define the MAGNITUDE (diameter and weight) of a drop of liquid.

Tau lepton

[general] Long-lived elementary PARTICLE; lifetime: $4.6 \pm 1.9 \times 10^{-13}$ s. One of the six (6) recognized and identified leptons: electron, NEUTRINO (e): ν_e , MUON: μ^- , NEUTRINO (μ): ν_μ , tau: τ , and neutrino (τ): ν_τ . The tau lepton has the shortest lifetime of all leptons, with the muon second (2.197×10^{-6} s) and the rest stable. Also known as the tau (see [Figure T.8](#)).

Figure T.8 Collision experimental design with Large Hadron Collider in Switzerland in search of the tau lepton.

Taylor, Brook (1685–1731)

[computational] Mathematician from Great Britain. Brook Taylor is best known for the Taylor Series, published in 1715 (see [Figure T.9](#)).

Figure T.9 Brook Taylor (1685–1731), painting by Louis Goupy.

Taylor, Geoffrey Ingram, Sir (1886–1975)

[computational, fluid dynamics, nuclear] Scientist and mathematician from Great Britain. Sir Geoffrey Taylor provided computational evidence of the Young double slit experiment based on the WAVE theory. Sir Taylor also contributed significantly to the development of PROPELLER blades, based on the fluid-dynamic aspects. Additional work was on the electric discharges under thunderstorms (see [Figure T.10](#)).

Figure T.10 Sir Geoffrey Ingram Taylor (1886–1975).

Taylor dispersion

[biomedical, fluid dynamics] Radial DISPERSION of a SOLUTE during an axial LAMINAR FLOW through a straight tube (the radius of curvature: infinity) with a circular CROSS SECTION. However, the principle also applies to curved conduits, more specifically in a bifurcated arterial and venous flow in the biological CIRCULATORY SYSTEM. Analogous applications can be derived for a turbulent flow as well. Based on the work by SIR GEOFFREY INGRAM TAYLOR (1886–1975). The FLUID flow for a PIPE with radius R , in the z -direction with the flow velocity in the z -direction w , distributed over a radius r has a velocity profile defined by $\vec{u} = w_0 [1 - (r^2/R^2)] e_z$, where e_z is the unit vector in the z -direction. For a solute, the DIFFUSION associated with this flow is defined by $(\partial[C]/\partial t) + \vec{u} \cdot \nabla[C] = D_{\text{diff}} \nabla^2[C]$, with $[C]$ the chemical concentration and

D_{diff} the DIFFUSIVITY. The diffusivity is linked to the Péclet number (Pe_d) through the effective diffusivity: $D_{\text{diff,eff}} = D_{\text{diff}} \left[1 + (1/192) Pe_d^2 \right]$, which indicates that the TAYLOR DISPERSION (the shear effect on the disbursement of the chemical concentration in the direction of flow) is more pronounced for a higher Péclet number (e.g., formation of “Taylor vortices”).

Taylor expansion

[computational] Discrete representation of a function as an infinite sum of derivatives of the function itself in a single point and was introduced by the British mathematician BROOK TAYLOR (1685–1731) in 1715, based on the work on curves and geometry by the Scottish astronomer and mathematician JAMES GREGORY (1638–1675) in 1668. Also known as TAYLOR SERIES.

Tectonic plates

[geophysics, mechanics] Concept introduced and validated in the 1960s considering the continents to be located on individual lithospheric plates of approximately 150 km thickness that apparently float on the magma of the ASTHENOSPHERE (see [Figure T.11](#)).

Figure T.11 Tectonic plates and fault-line between tectonic plates.

Tectonics

[acoustics, astrophysics/astronomy, chemical, electromagnetism, fluid dynamics, geophysics, mechanics, solid-state, thermodynamics] The study of the physical phenomena and processes of a planet's crust (*also see* EARTHQUAKE and SEISMIC) (see [Figure T.12](#)).

Figure T.12 (a) Types of tectonic plate boundaries and (b) diagram illustrating plate subduction.

Teflon®

[biomedical, chemical, mechanics] Brand name for polytetrafluoroethylene (PTFE), a synthetic fluoropolymer of tetrafluoroethylene; registered trademark from the DuPont corporation, discovered in

1938 by the chemist from the United States Roy Plunkett (1910–1994). The high MOLECULAR WEIGHT material has a very low coefficient of FRICTION; this will result in an extremely low degree of static and KINETIC FRICTION with respect to virtually any material. Teflon has a high stability temperature and is hence used as a nonstick coating for a broad range of industrial and commercial applications (e.g., pots and frying pans). The additional mechanical and chemically inert properties have provided ample applications as tape and gasket material (see [Figure T.13](#)).

Figure T.13 Burj Al Arab hotel in Dubai with a Teflon-coated screen that encloses the three sides of the Burj al Arab atrium. The screen covers a surface area of several hundred square meter and is made of glass fiber fabric with a thickness of approximately 1 mm; the Teflon® is intended to stop dirt from sticking to it.

Telegraph

T

[computational, electric, general] Device used for the decoding of information in a binary fashion and transmission by electrical means. The device was initially designed in 1792 by Claude Chappe (1763–1805), an engineer from France who also introduced the term “telegraph.” Claude Chappe started out with the semaphore concept, which uses an optical SIGNAL for conveying messages over great distances, either by the position of mechanical arms (also used in the Netherlands with the position of the blades/sails of the windmills, dating back to the seventeenth century), or towers with pivoting shutters. Subsequently SAMUEL FINLEY BREESE MORSE (1791–1872), a painter and inventor from the United States introduced the MORSE CODE for communication of succinct messages. The efforts of Samuel Morse led to the commercial proliferation of a consumer device. The later mathematical design is based on the mathematical and electronic efforts of the engineer Oliver Heaviside (1850–1925) from Great Britain. Note that semaphores

are still used for signaling in train traffic as well as directing traffic by police officers, and traffic LIGHT is also a clear example of semaphores (see [Figure T.14](#)).

(a)

(b)

(c)

Figure T.14 (a) Telegraph machine and operator and (b) old design ship communication telegraph. The device would “ping” a bell to indicate the desired operating instructions; for example, “full steam ahead.” (c) Example of modern rail traffic controlling semaphore device.

Telegraph equation

[biomedical, computational, energy, fluid dynamics] Mathematical differential equation describing the propagation of a periodic phenomenon (e.g., WAVE), developed by the scientist and engineer from Great Britain Oliver Heaviside (1850–1925). In electrical ENGINEERING, the telegraph equation describes the propagation of a harmonic wave over a conducting cable for analog data transmission.

The electrical potential (U_{pot}), which varies with time, is a function of the propagation path length ($d\tilde{z}$) and a function of TIME (t) as can be found by solving a one-dimensional differential equation: $(1/LC)(d^2U_{\text{pot}}/d\tilde{z}^2) = (d^2U_{\text{pot}}/dt^2) + [(R/L) + (\mathbb{R}/C)](dU_{\text{pot}}/dt) + (\mathbb{R}R/LC)U_{\text{pot}}$, where $\mathbb{R}$ represents the conductivity over a length of schematic. Alternatively for a conducting medium with properties inductance (L), capacitance (C), and RESISTANCE (R): $(d^2V_m/dt^2) - (c_1 + c_2)(dV_m/dt) = c_3^2(d^2V_m/d\tilde{z}^2) + c_1c_2V_m$, where $c_1 = (1/C_m)(1/R_m d\tilde{z})$, $c_2 = R_p/L_p$, and $c_3^2 = 1/L_p C_m$, with $\tilde{z}$ the direction of propagation along the length of the CELL (axon), and $\square_p$ and $\square_m$ with respect to the direction of propagation and the boundary ("shell" of the CONDUCTOR), respectively. The potential migration reduces to $d^2V_m/dt^2 = c_3^2(d^2V_m/d\tilde{z}^2)$ in the absence of resistance and electron/ionic leak current (e.g., POLARIZATION of either the insulating layer surrounding the cable or external FLUID or LIQUID), which is a plain HARMONIC OSCILLATION. Next to electronic transmission, the propagation of a wave pulse in liquid in FLUID DYNAMICS can be analyzed by implementing a perturbation on a steady-state axial flow $u(r, t)$ to derive the DISPERSION and frequency-dependent flow from developing the expression in a harmonic expansion by means of a Poisson series as $u(r, t) = u'(r)e^{i\omega_n t}$, ω_n represents the harmonics in the frequency pattern of the PULSATILE FLOW. This time-dependent expression can be substituted in the Poiseuille equation, providing the flow dynamic equivalent of the telegraph equation for the flow velocity as a function of radius and time as well as axial location: $u(\tilde{r}, t) = \text{Re}\{-(ia_n/\omega_n)e^{i\omega_n t}[1 - J_0(\sqrt{-i}\alpha(r/R))/J_0(\sqrt{-i}\alpha)]\}$, using a_n as defining the coefficients of the FOURIER SERIES for the polynomial series expansion in frequency, furthermore $\alpha^2 = \text{Re} * S_r$, and R is the radius of the vessel. In this expression, the following definitions are used: Re the REYNOLDS NUMBER, S_r the Strouhal number, and J_0 the first-order Bessel function. The frequency parameters for a non-Newtonian fluid, such as the pulsatile BLOOD flow in the arteries, are determined from the Strouhal number. The Strouhal number defines the ratio of the fluidic forces due to TURBULENCE phenomena with respect to the localized internal forces specifically as a result of localized flow accelerations. The Strouhal number provides a tool to estimate the time scale for VORTEX formation. The Strouhal number is defined as $S_r = \omega D/V$, with V the average (axial) flow velocity, D is the vessel diameter, and ω the ANGULAR VELOCITY of the (dispersive/turbulent) periodic phenomenon of flow. The flow characteristics are inherently tied to the flow rate, the tube diameter, and the pulsatile frequency of the flow mechanism.

Telemetry

[biomedical, general, mechanics, meteorology] The use of WAVES for gauging DISTANCE, direction, and MAGNITUDE (i.e., velocity) as well as wind direction, primarily based on ELECTROMAGNETIC (radio)-waves, but also by mechanical means (e.g., wind direction and velocity). Also used by BATS in ACOUSTIC format. An alternative interpretation is remote sensing, next to noninvasive sensing. The determination of BLOOD flow by acoustic and LASER DOPPLER flow METROLOGY can be considered telemetry as well (see [Figure T.15](#)).

Figure T.15 The use of telemetry by means of assisted device in tracking the migration pattern of birds.

Telescope

[astrophysics/astronomy, general, nuclear, optics] Device used to increase the RESOLUTION with respect to a distant phenomenon or object. Telescopes use a broad range of the ELECTROMAGNETIC SPECTRUM, from ULTRAVIOLET to the MICROWAVE. Telescopes operating in the visible spectrum provide a means to visually enlarge an object at a great DISTANCE. Telescopes operating in other parts of the electromagnetic spectrum require SIGNAL and image-processing techniques to reveal specific characteristics of the phenomenon under observation, such as a STAR or GALAXY. Radio telescopes are used in astronomy in order to observe in the radio-frequency and microwave bands by means of an array of dish antennas. RADIO telescopes often need to rely on INTERFERENCE properties to provide location-specific information. The first use of an optical telescope was described by the scientists and spectacle makers from Germany/the Netherlands, HANS LIPPERSHEY (1570–1619; also known as Johannes Lipperhey) and ZACHARIAS JANSSEN (1580–1640) in 1608, with contributions from Jacobus Metius (1571–1624; also known as Jacobus Adriaanszoon). GALILEO GALILEI (1564–1642) built his own telescope in 1609 based on the Dutch inspiration. A brief list of notable researchers in astronomy are NICOLAUS COPERNICUS (1473–1543), Tycho Brahe (1546–1601; Tyge Ottesen Brahe, scientist from Denmark), and EDWIN POWELL HUBBLE (1889–1953). Telescopes can rely on reflective imaging or refraction imaging. Optical telescopes use both REFLECTION and refraction, often in combination, where the reflection aspect provides a larger opening ANGLE and provides smaller constraints on the material properties. Long wavelength telescopes primarily rely on reflection-based focusing (*also see HUBBLE TELESCOPE and RADIO-TELESCOPE*) (see [Figure T.16](#)).

Figure T.16 (a) Picture of the telescope at North Carolina State University observatory in Durham, North Carolina; (b) image of the very large radio telescope array, consisting of 27 radioantennas, located in New Mexico; and (c) optical telescope at the base of the Matterhorn mountain in the Pennine Alps, located on the border between Italy and Switzerland.

TEM

[biomedical, imaging, nuclear, solid-state] See TRANSMISSION ELECTRON MICROSCOPE.

Temperature (T)

[general, solid-state, thermodynamics] Analogous to the definition of ABSOLUTE TEMPERATURE, temperature as a general definition may be interpreted as the aptitude for ENERGY to flow (i.e., heat) between two systems in contact, specifically from a high to low temperature (i.e., ZEROTH-LAW OF THERMODYNAMICS). Additionally temperature is the average kinetic energy of the atomic and MOLECULAR MOTION and is dependent on the atomic structure. In general, the solid-state and gaseous state can all be represented as an atomic GAS with the following characteristics: a one-atomic gas has $(3 + 0)$ degrees of freedom, a two-atomic gas has $(3 + 2)$ DEGREES OF FREEDOM, whereas the remaining multiatomic gases have $(3 + 3)$ of freedom, of which the first three are translational in a three-dimensional space (i.e., translational, vibrational, scissor action, and rotational) and the kinetic energy correlates with temperature as $(3/2)kT = KE = (1/2)mv^2 = (3/2)mv_0^2$, where k is the Boltzmann constant, m is the mass of the particles in MOTION (atoms/molecules), and v is the velocity of the motion. Temperature is expressed in either degree Celsius, degree Fahrenheit, or kelvin. The Fahrenheit scale [unit: °F] was introduced in 1717 by GABRIEL D. FAHRENHEIT (1686–1736), the CELSIUS SCALE [unit: °C, also known as the *centigrade scale*] was introduced by ANDERS CELSIUS (1701–1744) in 1742, and LORD (WILLIAM THOMPSON) KELVIN (1824–1907) introduced his temperature rendition [unit: K] in 1854. The Fahrenheit scale has 0°F defined as the MELTING POINT of water with ammonium chloride SALT (calibration point: ice and water with), a middle (third) point at the FREEZING point of distilled water at 32°F (based on the fractional distribution, i.e., powers of 2), and the upper reference the average adult HUMAN BODY temperature set at 96°F (measured with equipment and choice of MEASUREMENT, under the tongue, of the time) divisible by 12, as customary in the English unit system, with 1°F increments. Celsius uses the melting point of distilled water as the lower reference 0°C and the boiling point of distilled water as the upper calibration point at 100°C, subdivided in 100 segments. An alternative scale is the RANKINE temperature scale introduced by WILLIAM JOHN MACQUORN RANKIN (1820–1872) that follows Fahrenheit's example, but uses the ABSOLUTE ZERO defined similar to the kelvin ($T_R = (9/5)T_F$; in °R), all under standard pressure at sea level of $P = 101.325 \times 10^3 \text{ N/m}^2$. There is an easy conversion from Fahrenheit to Celsius: $T_C = (5/9)(T_F - 32)$. The Kelvin scale is similar to the Celsius scale with the elementary difference that the minimum temperature is the lowest temperature attainable (i.e., absolute zero: -273.16 K), also referred to as the *absolute temperature*. The conversion from degrees Celsius to kelvin is as follows: $T_C = T_K + 273.15$. Temperature is easily (and routinely) measured by EXPANSION, either by a change in pressure under constant volume, or by a change in volume under constant pressure (i.e., volumetric) (e.g., gas THERMOMETER; Galileo, 1592), or linear (LIQUID: e.g., water, ALCOHOL, mercury, as well as solid metals) by means of the expansion coefficient: $\Delta\ell/\ell = \alpha\Delta T$, with ℓ the length ($\sim$ column), $\Delta\ell$ the linear expansion, and α the linear expansion coefficient for the material in question. Otherwise temperature is derived from electric phenomena (bimetallic junctions changing electromotive force, V_{emf} , or conductivity as a result of the local temperature-dependent electron motion) and electronic properties (p - n junctions depending on the kinetic electron action), and finally colorimetric (i.e., change in COLOR due to temperature, alternatively used in quantifying colors). All mechanisms are assumed to operate within the linear response temperature range of the device, which imposes limitations. Since temperature is a measure of energy content, when two objects of unequal temperature are joined together the exchange of heat between the two bodies will strive for an equilibrium that has a direct correlation to the heat exchange, which in turn depends on the energy, mass, and temperature. The heat exchange will strive for equilibrium, eliminating the temperature gradient at the interface between two bodies at unequal temperatures while in contact. This defines the concept of thermal equilibrium. Combining the

temperature data with material properties such as volume characteristics yields state equations, such as the van der Waals state equation (see [Figure T.17](#)).

Figure T.17 Temperature gradient with respect to double glaze window, and presumed associated heat transfer.

Temporal period (T)

[acoustics, general, optics] The time frame for a harmonic event, which is directly linked to the **FREQUENCY** (ν) of the **OSCILLATION** as $T = 1/\nu$, expressed in seconds. In the electrocardiogram, for instance, the temporal period is the average time between the Q-peak for a range of QRS segments (see [Figure T.18](#)).

Figure T.18 Temporal period, in this diagram representing the acoustic wave in a medium.

Temporal width

[imaging, optics, quantum, ultrafast phenomena] {use: spectroscopy, hyperspectral imaging} Pulse duration of picoseconds (10^{-12} s) and shorter duration. The temporal width provides the means to measure phenomena that occur on a very short time scale, by essentially “FREEZING” the “MOTION,” as well as chemical processes of **ATOMS** and **MOLECULES**. The short temporal width allows for a detailed analysis of chemical constituents and the stages involved in the development of a chemical reaction. Ultrashort pulses inherently have a broad spectral band and are often characterized by a high **ENERGY** (i.e., irradiance) at the peak emission. Also used in coherent **X-RAY** imaging for short biological event such as intercellular **PROTON** motion. On a biomedical diagnostic level, the analysis of wound healing requires terahertz **SPECTROSCOPY**.

for an accurate classification of burn wounds, and the apropos identification of the particular physiological processes involved. Two important spectroscopic phenomena in biological functionality in the ultrashort timeframe are found in PHOTOSYNTHESIS and VISION. The LIGHT interaction in the RODS and CONES of the EYE (receptor protein: rhodopsin, CHROMOPHORE derived from vitamin A) as well as in both the SKIN and in plants with respect to the conversion of light into CHEMICAL ENERGY and oxygen production takes place on a femtosecond scale. Rhodopsin is present in both rods and cones for vision. In vision, the QUANTUM states of the excited molecules yield information on the energy transfer. The chemical processes of 11-cis retinal in rhodopsin isomerization to all-trans bathorhodopsin in a photochemical process on PHOTON absorption (energy: $h\nu$) that takes place in a 3.0 ± 0.7 ps transfer between two molecular species, approximately 1 ps into the photochemical process. One significant detectable interaction is the 11-cis to 12-cis isomerization [$C_{11} = C_{12}$ – isomerization], which reveals itself through vibrational modes in the polyene backbone (torsions); specifically the low $C_{12} - H$ VIBRATION frequency in bathorhodopsin that shows anomalous behavior. The first chemical process is associated with a transition defined by the Frank–Codon state, which has an approximate lifetime of 200 fs.

Tensile force ($\bar{F}_T$)

[general, mechanics] Force with the potential for stretching a material (*also see* TENSION).

Tensile strain

[mechanics] A rod under tension will express a normal strain, increasing in length until the ULTIMATE TENSILE STRENGTH is reached and the device will shear-off (separate) (see [Figure T.19](#)).

Figure T.19 Tensile strain.

Tensile (ultimate) strength

[engineering, general] Indication of the permissible mechanical shear stress and strain. It is of particular interest for the prediction of mechanical failure of a structure or device. The ULTIMATE TENSILE STRENGTH follows from the graphical interpretation of a plot of stress versus strain, where the stress will have an optimum, which corresponds to the ultimate TENSILE STRESS. The shear strain limit will be defined as a function of the shear strain ANGLE of distortion: $\gamma_s = \sin^{-1}(\Delta x / \ell_0) \approx \Delta x / \ell_0$, with Δx the lateral displacement

at the far end of the construction/device and ℓ_0 the characteristic length (i.e., the orthogonal DISTANCE to the origin with respect to the angle of rotation of the material strain motion). Certain biological materials can stretch at greater than 800% of the EXPANSION of most natural rubber, but not reaching the stretch for latex or nylons. The rubber balloon was introduced, almost accidentally, as the result of GAS-LAW experimentations by MICHAEL FARADAY (1791–1867) in 1824 (see [Figure T.20](#)).

Figure T.20 Tensile strength tow truck pulling car out from snowbank.

Tensile stress

[mechanics] The normal force in response to the tensile force on a cross-sectional area in a solid (e.g., rope, rod) (see [Figure T.21](#)).

Figure T.21 Tensile stress.

Tension (F_T or τ)

[general, mechanics] SCALAR quantity of the tensile force between neighboring ELEMENTS, either in the linear direction or parallel plane. The tension in a rope will be equal in every point between the two attachment locations where an external force is applied. For a special case of surface elements (*see* SURFACE TENSION). In liquids, there is no friction and hence only normal tension will apply. In cases of lateral forces, TANGENTIAL TENSION (i.e., stress) needs to be taken in consideration (*see* Figure T.22).

Figure T.22 Tension.

Tension, surface

[hydrodynamic] *See* SURFACE TENSION. *Also see* CAPILLARITY and SURFACE ENERGY.

Tension, tangential

[mechanics] *See* STRESS.

Tensor

[atomic, fluid dynamics, solid-state] In order to place phenomena in symmetry, group theory treats the average effects, specifically applied to crystals, and respectively lattices, but also applicable to, for instance (but not limited to), FLUID DYNAMICS, general relativity, and ELASTICITY. The tensor concept introduces mathematic and geometric framework that are a generalization of vectors, matrices, and scalars. A tensor has multiple dimensions, indicated by the indices that represent the DEGREES OF FREEDOM in the applicable space. The format of the tensor as an “indexed” parameters resembles the notation of the matrix ELEMENTS, apart from the fact that the number of indices and placement of indices are arbitrary and not limited to a matrix pattern

$$A = \begin{bmatrix} a_{11} & \cdots & a_{1m} \\ \vdots & a_{ij} & \vdots \\ a_{n1} & \cdots & a_{nm} \end{bmatrix}$$

(matrix ELEMENT a_{ij}); instead tensors are found as a_{ijk} ; a_i^{jk} ; a^{ijkl} ; etc. A tensor of rank 1 is a SCALAR ($3^0 = 1$ component, e.g., temperature), tensor of rank 2 is a vector ($3^1 = 3$ components, e.g., velocity), tensor of rank 3 is a dyad ($3^2 = 9$ components, e.g., permeability, stress, flow [vortices]), tensor of rank 4 is triad ($3^3 = 27$ components, e.g., VELOCITY POTENTIAL), and so on.

Terminal velocity

[general, mechanics] The velocity of an object when all forces are balanced, resulting in a net force of zero. Under freefall, this means that GRAVITATIONAL ACCELERATION and DRAG are canceling out when a certain velocity is reached, where the ultimate velocity is a function of the elapsed time and the sum of the accelerations is a function of time. The object is in equilibrium at this point: $\sum \vec{F}_i = 0$. The terminal velocity (v_T) of a sphere with density ρ_s , traveling in a FLUID with density ρ_f can be approximated based on the Stokes STREAM FUNCTION as $v_T = (2/9)[(\rho_s - \rho_f)/\eta]gR^3$, where η is the VISCOSITY, g the acceleration, and R the radius of the spherical object. Analogously, for a cylinder in flow, the VORTICITY ($\vec{\omega} = \partial\chi/\partial\varphi$; φ the ANGLE of the velocity with the VORTEX axis) surrounding the cylinder will provide a significant influence, assuming the cylinder traveling long ways in the flow, in response to the balancing torque on the “rod.” The terminal velocity can be derived from: $v_T = [(1/2) - \gamma^* - \log((1/2)k^*R)]C$, where γ^* represents the first term in the EXPANSION: $\int_0^\infty e^{-k^*r} \cosh \vec{\omega} d\vec{\omega} = -[\gamma^* + \log((1/2)k^*r)]Y_0(k^*r) + s_1(k^{*2}r^2/2^2) + s_2(k^{*4}r^4/2^2 4^2) + s_3(k^{*6}r^6/2^2 4^2 6^2) + \dots$, where $Y_0(k^*r)$ is a zero-order Bessel function of the second kind, $k^* = |\mu|/2\eta$ an indicator of the MAGNITUDE of the viscous forces (tied to the viscous forces: $\eta\nabla^2 u$; $\eta\nabla^2 v$; and $\eta\nabla^2 w$), and C is the coefficient in the series for the vortex field solution developed in the WAKE $\chi = Ce^{k^*x} \int_0^\infty e^{-k^*r} \cosh \vec{\omega} d\vec{\omega}$, with $\vec{\omega} = \partial\chi/\partial\varphi = (3/2)\mu R(1 + k^*r)(\varphi/r^3)e^{-k^*(r-x)}$ the vorticity, and r the radius; as a SOLUTION to $\mu = -(\partial\phi/\partial x) + (1/2k^*)(\partial\chi/\partial x) - \chi$, where ϕ is the VELOCITY POTENTIAL and u the velocity in the direction of net flow (see Figure T.23).

Figure T.23 Terminal velocity without parachute.

Tesla, Nikola (1856–1943)

[general] Scientist from Croatia. Nikola Tesla dedicated his research to the electrical ACTIVITY of charges and the MAGNETIC FIELD effects. One of Tesla's major contributions to modern ENGINEERING is the alternating current electrical system, leading to the electromotor and the GENERATOR. The ac-induction MOTOR is very actively in use with modern hybrid and electric automobiles. The “Tesla coil” invented in 1891 has found many applications, such as the one in RADIO technology. The Tesla coil constitutes a high-voltage low-current high frequency electrical resonator that can go beyond the frequency range of an electrical TRANSFORMER. The Tesla coil is also used for display purposes with PLASMA arcs propagating through AIR.

Nikola Tesla designed the hydroelectric power plant in operation at Niagara Falls, New York, the United States in 1895 (see [Figure T.24](#)).

Figure T.24 Nikola Tesla (1856–1943).

Tesla (T)

[general] Unit for the MAGNITUDE of a MAGNETIC FIELD, adopted in the SI UNITS in 1960. The unit is named after a pioneer in the magnetic field theory NIKOLA TESLA (1856–1943). The unit has the following equivalents: $T = (\text{Vs}/\text{m}^2) = (\text{N}/\text{Am}) = (\text{Wb}/\text{m}^2) = (\text{kg}/\text{Cs})$. The range of magnetic field strength is broad. Examples of the magnetic field strength under various conditions are as follows: for the atomic NUCLEUS: $10^{12} T$; at the surface of a NEUTRON STAR: $10^8 T$; artificially produced under laboratory conditions: $\sim 10^3 T$; a small MAGNET: $10^{-2} T$; kitchen blender: $\sim 10^{-3} T$; the earth's magnetic field $\sim 10^{-4} T$; high voltage electric transmission lines (within close proximity): $10^{-4} T$; the HUMAN BODY: $\sim 10^{-10} T$; the smallest value in shielded environment: $10^{-14} T$.

Thales (c. 624–546 BC)

[general] Greek scientist and philosopher. Founder of the first principles of scientific method, separating divine intervention from phenomena (i.e., natural events) that have a cause that can be explained scientifically and theoretically. Some later Greek philosophers credited Thales with the first introduction of celestial navigation referring to Ursa Minor (i.e., “Little Bear”) as the point of reference. Records also mention that he proposed water as the primary ELEMENT, the source of all media (see [Figure T.25](#)).

Figure T.25 Impression of how Thales (ca. 624–546 BC) may have looked like.

Theodolite

[general, geophysics] Instrument designed to provide the **ANGLE** with respect to a horizontal plane using a telescopic viewer that can pivot in vertical and horizontal directions, introduced by and used in areal construction and land surveying. The theodolite measures the azimuth angle. The concept was introduced in the 1500s and is in everyday use today (see [Figure T.26](#)).

Figure T.26 Theodolite.

Thermal conductivity

[thermodynamics] Coefficient of **HEAT TRANSFER** (heat transfer rate: $\dot{Q} = dQ/dt$) for a medium with **CROSS SECTION** A over a length ℓ and with an applied thermal gradient ($T_b - T_l$) to provide $\dot{Q} = \lambda_T [A(T_b - T_l)/\ell]$.

Thermal diffusivity ($\alpha_{\text{dif}} = \kappa/\rho c_p$)

[thermodynamics] Where κ the thermal conductivity, ρ the density, and c_p the heat capacity. Thermal **DIFFUSIVITY** describes the ability of an object to adjust to the ambient changes in temperature and the rate of change to reach equilibrium. A high thermal diffusivity means that an object adjusts rapidly, whereas a low thermal diffusivity might entail a larger **ENERGY** requirement.

Thermal energy

[general, nuclear, thermodynamics] Atomic and molecular kinetic **ENERGY**, contained as the temperature of an object. Thermal energy is part of the **CONSERVATION OF ENERGY** principle. Thermal energy may develop due to **FRICTION** or result from combustion.

Thermal equilibrium

[engineering, general, thermodynamics] Conditions for which there is no transfer of heat, all bodies with a system are at the same temperature. (*also see* **ZEROTH LAW OF THERMODYNAMICS**).

Thermal expansion

[engineering, general, nuclear, thermodynamics] Increase in **VOLUME** (V) for a system due to a change in the **TEMPERATURE** (T) of the system, generally considered under constant **PRESSURE** (P). The volume expansion is defined by the volume expansion coefficient as $\gamma_{\text{th}} = (1/V)(dV/dT)_P$. Generally the thermal expansion

coefficient is a function of temperature itself, expressed as $\gamma_{\text{th}} = a + bT + cT^2$, where a , b , and c are material constants. The EXPANSION for metallic objects is subject to both LATTICE expansion and conduction electrons, expressed by the SPECIFIC HEAT under constant pressure: $c_p = a_{\text{el}}T + a_{\text{lat}}T^3$, where a_{el} and a_{lat} are coefficients with respect to the contributions due to the electrons and the lattice. The electron and lattice expansion translates into the GRÜNEISEN EQUATION for thermal expansion: $\gamma_{\text{th}} = (1/VB_s)(\gamma_{\text{el}}a_{\text{el}}T + \gamma_{\text{lat}}a_{\text{lat}}T^3)$, where B_s is the adiabatic bulk modulus. This reduces to $\gamma_{\text{th}} = \gamma_{\text{GR}}(c_p/VB_s)$, with γ_{GR} the Grüneisen coefficient, indicating the temperature dependence for the expansion. Water is one of the few media that decreased in volume between the FREEZING point and a few degrees above freezing, with the highest density at 4°C. A large segment of metals has an almost uniform expansion coefficient around the MELTING POINT for the LIQUID phase as $\gamma_{\text{th}} \sim 10^{-4} \text{ K}^{-1}$. Under certain conditions, linear thermal expansion is required, where $\gamma_{\text{th}} = 3\alpha_{\text{th}}$; $\alpha_{\text{th}} = (1/L)(dL/dT)_p$, L the characteristic length, and α_{th} the linear expansion coefficient (see Figure T.27).

Figure T.27 Thermal expansion for a hot-air balloon, using a flame to heat up the air that will force the balloon filled with expanding air to increase in volume that will provide it buoyancy. The volume of hot air inside the balloon has a lower density and is hence lighter than the colder surrounding air providing an upward force.

T

Thermal neutrons

[atomic, nuclear] Slow moving NEUTRON, with velocities in the distribution of room temperature AIR molecules. Thermal neutrons were found very inquisitive for the examination of materials, from LIGHT to heavy metals (including uranium) during the research into the structure and ISOTOPE formation performed by ENRICO FERMI (1901–1954).

Thermal wave

[acoustic, quantum, solid-state, thermodynamics] The ability to produce CAPILLARY WAVES (at an interface) on a molecular scale by means of thermal MOTION. The thermal wave is confined by the SURFACE TENSION (σ_{surface}) and can be described as the ENERGY content ($E_{\text{SurfaceTension}}$) in the lateral displacement (height: h) along the surface (in the x - and y -directions) as $E_{\text{SurfaceTension}} = \sigma_{\text{surface}}$

$\int \{ \sqrt{1 + [(db/dx)^2 + (db/dy)^2]} - 1 \} dx dy \cong (\sigma_{\text{surface}}/2) \int [(db/dx)^2 + (db/dy)^2] dx dy$, where the displacements are of a small AMPLITUDE (also see SURFACE ACOUSTIC WAVE and CAPILLARY WAVE).

Thermionic emission

[atomic, nuclear] Release of electrons from a METAL surface under heating, generally heated through an electrical current. The process was recognized by Thomas Alva Edison (1847–1931) in 1883. The thermionic emission is used for the generation of X-RAY from the impact on a metal target (e.g., bismuth or tungsten).

Thermistor

[electronics, general] Material that has a RESISTANCE (R) that varies with applied temperature. The TEMPERATURE (T) can be derived from the CURRENT (I) under an applied VOLTAGE (V) through OHM'S LAW: $V = IR$, assuming a linear response with respect to temperature change: $\Delta R = \epsilon_{\text{const}} \Delta T$. The mechanism of action is different from a THERMOCOUPLE.

Thermoacoustic imaging

[optics, thermodynamics] See PHOTO-ACOUSTIC IMAGING and SCANNING ACOUSTIC MICROSCOPE.

Thermocouple

[electromagnetism, general, thermodynamics] Temperature sensor, generally made by joining two metals together that will provide a voltage that is a function of the temperature based on the SEEBECK EFFECT, as recognized by the German scientist Thomas Seebeck (1770–1831). One commonly used thermocouple uses two alloys: chromel (consisting of 90% nickel and 10% chromium) and alumel (consisting of 95% nickel, 2% manganese, 2% aluminum, and 1% silicon). The potential difference (V , measured at the distal end of the wire; the junction of the two metals generates a balancing current to cancel out the external potential difference) as a result of temperature (T) is defined as $V_b - V_c = \int_{T_c}^{T_b} [S_A(T) - S_B(T)] dT$, with $S_A(T)$ and $S_B(T)$ the Seebeck coefficients for materials A and B, and the subscripts c_b and c_c represent the temperature at the two junctions. The inverse process with respect to the thermocouple principles is the Peltier effect (see Figure T.28).

Figure T.28 Thermocouple used for temperature measurement.

Thermodynamics

[biomedical, chemical, engineering, mechanics, quantum, thermodynamics] Branch of engineering and physics that deals with the aspects of work, heat, temperature, and equilibrium conditions. Thermodynamics is based on the following four laws: ZEROth LAW OF THERMODYNAMICS (any two systems in contact at

the same temperature are in thermal equilibrium); **FIRST LAW OF THERMODYNAMICS** (conservation of ENERGY, INTERNAL ENERGY, and work and heat need to balance); **SECOND LAW OF THERMODYNAMICS** (heat will not flow from a cooler to warmer location without external assistance); and the **THIRD LAW OF THERMODYNAMICS** (it is impossible to reach **ABSOLUTE ZERO** temperature [in kelvin] by any process of finite number of steps). The concept of **PERPETUAL MOTION** is rejected based on at least the last two laws. Other aspects of thermodynamics include statistical **MECHANICS** and thermometry.

Thermodynamics, first law of

[energy, fluid dynamics, general, thermodynamics] The change in the **INTERNAL ENERGY** (U) of a system is the confluence of the **HEAT** (Q) introduced in the system and the work (W) done by the system on the surroundings, formulated as $\Delta U = \Delta Q - \Delta W$. The work performed can be mechanical: $W_m = P\Delta V + V\Delta P$, with P the internal pressure and V the volume of the system; or when the work is electrical: $W_e = -nF_a\Delta V_e$, with n is the number of charges transferred in the process, $F_a = 96,485$ C/mol the **FARADAY CONSTANT**, and ΔV_e is the maximum difference in electrical potential resulting from the transferred charges. This law is another version of the **CONSERVATION OF ENERGY**.

Thermodynamics, second law

[biomedical, energy, fluid dynamics, general, thermodynamics] If a system is isolated (no ENERGY is added to it) its entropy is destined to increase with time. Consider a flower that has been cut and is left in a closed container without water. The flower and stem will eventually **DECAY**, meaning that the entropy of the system has increased. Life is one of the most obvious examples where the requirement of energy input to sustain order is evident. Such processes are called **energonic**, in which the energy of the final state is higher than the energy of the initial state.

Thermodynamics, third law

[biomedical, energy, fluid dynamics, general, thermodynamics] For any mixture of constituents, known as a system, there exists one stable equilibrium that will be at zero temperature (0 K; zero degrees kelvin). The third law also states that the **ABSOLUTE ZERO** kelvin cannot be reached by any finite number of discrete steps. An equivalent statement relates to the fact that the **CARNOT ENGINE** can never have the perfect efficiency. (*also known as* **NERNST PRINCIPLE**).

Thermodynamics, zeroth law of

[general, thermodynamics] Concept introduced by **JOSEPH BLACK** (1728–1799) around 1760. The zeroth law describes the fact that every system will be endowed with the property of temperature. Placing two systems in contact will establish thermal equilibrium where both systems possess the identical temperature and no net heat will be transferred. When systems A and B are in thermal equilibrium, possessing the same physical quantity of temperature, as are systems B and C, then systems A and C are (also) in equilibrium.

Thermography

[fluid dynamics, imaging, thermodynamics] Imaging method using the **INFRARED** “signature” to identify the temperature distribution. The thermography concept is based on **PLANCK’S LAW** (accurate) or alternatively **Wien’s displacement law** (approximation). **WIEN’S DISPLACEMENT LAW** provides the peak emission wavelength (λ) as $\lambda = (2.898 \times 10^{-6}/T)$ nm, with temperature (T) in kelvin. The **PLANCK’S RADIATION LAW** gives the radiant power as a function of wavelength as $W = 2\pi hc^2/\lambda^5 (e^{hc/\lambda k_B T} - 1)$ W/m²μm. Thermography uses the spectral profile in near infrared (wavelength range $\lambda = 0.66$ – 2 μm); mid-infrared (wavelength range: $\lambda = 3$ – 5 μm); to long infrared (wavelength range: $\lambda = 7$ – 14 μm) spectrum, depending on the specific application. The two primary thermal imaging wavelength bands are $\lambda = 3$ – 5 μm and $\lambda = 8$ – 12 μm. Thermographic imaging owes its limitations to these two specific bands based on the spectral response limitations of the available photodetectors next to the transmission passband windows of the **ATMOSPHERE**; specifically within a bandwidth portion.

The monochromatic emissive power of a black-body radiation at the typical room temperatures (296 K) has an emission peak at $9.6\text{ }\mu\text{m}$. For analysis, the **EMISSIVITY** of the surface is assumed to be $\sim 96\%$ ($\epsilon_T = 0.96$; note that polished aluminum or platinum has an emissivity of only 4% , whereas water and human tissue is $\sim 96\%$, and soot 99%), but in cases otherwise known corrections can manually be entered for the surface with respect to the imaging device software processing and user interface. The modern day photodetectors use various mechanisms, ranging from photovoltaic to photodiode to photoresistive. Photovoltaic operation relies on the electron release based on the work function of the medium, generating a current that is proportional to the overall collected **PHOTON** radiance within a bandwidth. A photodiode renders a reverse bias current resulting from photoenergy exposure. The photoresistive **ELEMENT** changes its charge-carrier density under the influence of photon **ENERGY**; this type of device is semiconductor based. Typical photoresistive **ELEMENTS** designed for the $\lambda = 8 - 12\text{ }\mu\text{m}$ band are MCT ($\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$) detectors, one of the few molecular structures that has a small enough bandgap with the **VALENCE BAND**. The detectors can be actively balanced in a Wheatstone configuration to minimize the conductive heating aspects, which will influence the sensitivity and accuracy. Generally a CCD imaging device uses MOSFET photodiodes that operate based on charge depletion under exposure. Each **PIXEL** is its own MOSFET element. Thermographic cameras are constructed with an array of infrared sensitive elements (pixels) that is processed for **MAGNITUDE** with a certain spectral band to provide the spatial distribution of surface temperatures. Virtually all thermographic-sensing devices require cooling, primarily designed to reduce the thermal noise as well as to increase the dynamic range. The cooling processes can be either by means of **LIQUID** nitrogen (temperature 77.4 K , -196°C) or through Peltier elements (thermopile), next to Joule–Thompson cooling devices (relying on isentropic **EXPANSION** of a pressurized **GAS**, similar to household refrigeration). Because of the fact that infrared **RADIATION** is readily attenuated by any material except for **AIR** and **VACUUM**, only the external surface of an object is analyzed for temperature. Any coating, plastic **BARRIER**, or wax/**OIL** covering will change the spectral profile of the **LIGHT** emitted from the **BLACK BODY**, hence altering the perceived temperature. Thermal imaging is subject to a variety of **NOISE** sources, ranging from thermal noise to shot noise (intrinsic semiconductor defect) and the random generation of charge carriers/holes (G–R noise; generation–recombination noise), which is not thermally activated, and has a spectral profile. Night-vision instrumentation also provides a form of thermographic imaging since it applies to near infrared, only slightly above the **RED** vision cut-off. Infrared imaging dates back to 1929, starting with night **VISION**, designed by the Hungarian scientist Kálmán Tihanyi (1897–1947). The next developmental **PHASE** was a spectral line scanner, which reconstructed images from obtaining emissions from points on parallel lines traced out on the surface of the object as designed by Texas Instruments in 1947, requiring up to an hour exposure. The last major breakthrough prior to the current state-of-the-art instrumentation was through pyroelectric scanning integrated with a full surface view developed by Michael Francis Tompsett (1939–) in 1969, later on perfected with solid-state sensor technology (CCD). (see **BLACK-BODY RADIATION**) (see Figure T.29).

Figure T.29 False-color image captured by thermography camera displaying temperature distribution of an object based on the Planck radiation profile, by means of collection of infrared radiation. Most thermographic cameras operate in the wavelength band of $3 - 5\text{ }\mu\text{m}$, other detection bands are available, including but not limited to, $1 - 2\text{ }\mu\text{m}$ and $8 - 12\text{ }\mu\text{m}$.

Thermokinetic oscillator

[chemical, energy, thermodynamics] *See* OSCILLATORY REACTION.

Thermometer

[energy, fluid dynamics, general, geophysics, thermodynamics] Device designed to quantify local temperature. The mechanism of action for the determination of the temperature can be THERMOCOUPLE based, thermo-electric (semiconductor), or linear EXPANSION of a FLUID in a confined tube under vacuum. The most well-known thermometers are the mercury and ALCOHOL liquid thermometers and the thermocouple-based probe, next to the thermographic (INFRARED sensitive) semiconductor sensor used for in-ear thermometry (see Figure T.30).

Figure T.30 Illustration of the use of a thermometer to measure body temperature and establish whether the person has a fever.

Thermonuclear energy

[atomic, general] ENERGY released from NUCLEAR FUSION or NUCLEAR FISSION processes (*see* THERMONUCLEAR FISSION *and* THERMONUCLEAR FUSION).

Thermonuclear fission

[atomic, general] Most nuclear power plants operate on induced fission of uranium-235, under prodding from colliding neutron (η). In this process, the NEUTRON briefly merges with the uranium to subsequently disintegrate in barium-138, krypton-95, and three new neutrons. This process results in the release of ENERGY that is based on the energy transfer for the nuclear binding forces in the molecular balance:

$${}_0^1\text{n} + {}_{92}^{235}\text{U} \rightarrow {}_{92}^{236}\text{U}^* \rightarrow {}_{56}^{141}\text{Ba} + {}_{36}^{92}\text{Kr} + 3{}_0^1\text{n} + 220\text{ MeV},$$
 where some energy is applied to the recombination (~ 20 MeV). The neutrons released in the FISSION process can continue to fuel the fission process. The effective 200 MeV fission energy almost all goes into THERMAL ENERGY (at least a verified 165 MeV as kinetic energy, whereas an additional 10 MeV out of all 200 MeV is released as kinetic energy, not as the anticipated neutrinos; 7 MeV as kinetic BETA PARTICLES [totaling 182 MeV in kinetic energy, producing thermal effects: $\text{KE} = (3/2)k_B T$]; next to 5 MeV as kinetic neutrons [used for fission] and the remaining theoretical

distribution is 7 MeV + 6 MeV to gamma RADIATION; primary and secondary) (see NUCLEAR FISSION and FISSION) (see Figure T.31).

Figure T.31 Nuclear chain reaction for uranium fission.

Thermonuclear fusion

[atomic, general] Most galactic stars operate on the process of NUCLEAR FUSION, joining two light nuclei (e.g., hydrogen (H)/proton (${}^1_0\text{n}$)) into larger/heavier nuclei: ${}^1_0\text{n} + {}^1_0\text{n} \rightarrow {}^2_0\text{H} + e^+ + \nu + 0.42 \text{ MeV}$, e^+ a positron that will annihilate a free electron and release an additional 1.02 MeV of ENERGY and ν a NEUTRINO. The gain in energy is provided based on the fact that the BINDING ENERGY is different for a set number of nuclides based on the ATOM number. Protons can be brought in close contact to the point where they will overcome their Coulomb repulsion. The KINETIC ENERGY (KE) to achieve proximity will need to exceed the center-to-center potential energy PE (Coulomb energy) of approximately 0.14 MeV, for separation of $r = 10^{-14} \text{ m}$ for the respective protons. This energy level equates to an approximate temperature of $T = 1 \times 10^9 \text{ K}$ ($KE = (3/2)k_bT$, $k_b = 1.3806488 \times 10^{-23} \text{ m}^2\text{kg/s}^2\text{K}$ Boltzmann constant). In practicality, the effective fusion temperature is 50 times lower (only at 2% of the thermal equilibrium) due to the fact that there will be an energy distribution around the calculated maximum energy, next to TUNNELING events. Fusion can be used to generate power on an artificial basis; however, most nuclear power plants are fission plants. The FUSION

plants in experimental use operate on tokamak (MAGNETIC) principles or laser INERTIA confined plasmas (see NUCLEAR FUSION and FUSION) (see Figure T.32).

Figure T.32 Diagram of nuclear fusion and energy balance.

Thermophysical properties

[thermodynamics] Theoretical and experimental parameters associated with a single constituent system in one-phase, two-phase, or three-phase states. The system consists of n molecules in a volume V , specific volume: $v_V = V/n$ with internal ENERGY (U), specific internal energy: $u_U = U/n$, entropy (S), and respectively specific entropy: $s_S = S/n$ and has a TEMPERATURE (T), PRESSURE (P) and DENSITY ($\rho = m/V$, for a PHASE with mass m of a chemical with MOLECULAR WEIGHT M). The amounts of constituents can be expressed in MOLE or mol (i.e., GRAM MOLE). With respect to phase transitions, the following specific thermophysical properties apply. The critical pressure (P_c), at which the LIQUID and VAPOR phase are treated as identical. The CRITICAL TEMPERATURE (T_c), at which the vaporization process reduces to an infinitesimal event. And an additional critical specific volume is also identified: v_{Vc} . Combining the three conditions of critical pressure, critical temperature, and critical specific volume yields the critical state or critical point. Particular to the form of AGGREGATION at the phase changes, there are specific LATENT HEAT values that define the energy requirements to accommodate the PHASE TRANSITION from one phase to the other. For a two-phase mixture, the chemical potential μ_i defines the phase MIXING under the CLAUSIUS–CLAPEYRON RELATION. Next to the specific latent heat at the phase transitions, there is also the specific heat under constant pressure (c_p) and SPECIFIC HEAT under constant volume (c_v) that both define the heat requirements per degree of temperature rise per unit mass. The equation of state provides a

means to interconnect a range of thermophysical properties and predict the course of events. Furthermore during EXPANSION and compression, the thermophysical properties of isothermal compressibility (K_T) and isobaric expansion (α_p) are important for the description of a process, plus they tie into the equations of state. The final thermophysical property on the list is the speed of SOUND for the medium under particular values of the aforementioned thermophysical properties. The speed of sound (v_s), as all the other thermophysical properties, can be measured and is correlated to some of the other properties through $v_s^2 = (\partial P / \partial \rho)_{ss} = -(v_V / M)(\partial P / \partial v_V)_{ss} = -(v_V / M)\{ (c_p / c_v)(1 / K_T v_V) \} = (c_p / c_v)(1 / \rho K_T) = \gamma_r (1 / \rho K_T)$, where γ_r is the ratio of the specific heats.

Thermoscope

[general, thermodynamics] THERMOMETER equivalent designed by GALILEO GALILEI (1564–1642), however, without a scale, introduced in 1617. A bowl partially filled with LIQUID has a tube leading upward where the rising liquid can spill into a bulb. The GAS pressure in the partially filled bowl will exert pressure on the fluid surface, pushing the liquid up through the tube, where the fill fraction of the bulb will be an indirect function of the temperature. The first practical temperature scale was introduced by OLAUS ROEMER (RØMER) (1644–1710) in 1701; followed shortly by GABRIEL DANIEL FAHRENHEIT (1686–1736) in 1717. Without much consequence at the time, a physician from France, Jean Rey (1583–1645) turned the Galilei thermoscope upside down and filled the bulb with water and started using it for measuring body temperature as a relative value in 1631, a definite preamble to the modern thermometer (see [Figure T.33](#)).

Figure T.33 Thermoscope.

Thermosphere

[energy, geophysics, thermodynamics] Shell of the Earth's ATMOSPHERE, the layer with the greatest thickness; spanning from 85 to 500 km. The thermosphere is located above the MESOSPHERE and has the EXOSPHERE on the outside. Within this layer, gaseous molecules and atoms are ionized under the exposure of the sun's short ULTRAVIOLET RADIATION. This ionization is what is observed as the auroras: AURORA BOREALIS and AURORA AUSTRALIS. The IONIZATION layer also provides a "reflective" layer for RADIO communications. Especially long-wave electromagnetic radiation can reflect off the ionized layers in the atmosphere and back from the earth's surface and allow long-wave radio waves to travel half-way around the EARTH (e.g., ham radio transmissions from Australia can be received in the United States, depending on atmospheric conditions). The temperature in the thermosphere increases with altitude as a result of the solar interaction. The thermosphere has a dynamic character, including atmospheric tides, a THERMAL WAVE pattern driven by DIURNAL heating. The atmospheric tides form a global OSCILLATION in the atmosphere. Atmospheric tides

are also common in the TROPOSPHERE and the STRATOSPHERE, based on the solar absorption in the high concentration of water VAPOR and ionization of oxygen to ozone. Based on the solar interactions, the tides have a period on the order of 12 and 24 h intervals; however, the periods become longer with greater altitudes. The flow direction of the tides is also subject to the orientation of the earth's axis with respect to the orbit around the SUN (seasonal fluctuations). The atmospheric tides are affected by gravitational influences next to the solar heating, and hence are also dependent on the lunar orbit. Atmospheric tides are considered as linear perturbations and are eigenvalues of the Hough functions. The Hough functions are special cases of the Laplace tidal equations. The LAPLACE EQUATION for the tidal WAVE of the atmospheric flow uses the Hough EIGENFUNCTION ($\Theta_n(\varphi_e)$) and Hough eigenvalues ($\zeta_n = (2\omega_e R_e)^2 / g(r, \varphi) r_n$, where $g(r, \varphi)$ is the GRAVITATIONAL ACCELERATION as a function of global atmospheric location) and is written as $L\Theta_n(\varphi_e) + \zeta_n \Theta_n(\varphi_e) = 0$, with the Laplace tidal operator $L = (\partial/\partial\Phi^*) \{ [(1 - \Phi^{*2}) / (Z^2 - \Phi^{*2})] (\partial/\partial\Phi^*) \} - [1 / (Z^2 - \Phi^{*2})] \{ (\kappa_z / Z) [(Z^2 + \Phi^{*2}) / (Z^2 - \Phi^{*2})] [\kappa_z^2 / (1 - \Phi^{*2})] \}$, introducing $\Phi^* = \sin \varphi_e$ and $Z = v_e / 2\omega_e$. The solutions are placed in the reference frame longitudinal (θ_e) and latitude location (φ_e), with the angular velocity of Earth (ω_e), the atmospheric density ($\rho \propto e^{-r/H}$, r the altitude, H_a the “thickness” of the atmosphere), and $\kappa_z = 2\pi/\lambda_z$ the zonal wavenumber, λ_z is the zonal wavelength, v_e zonal frequency, r the altitude, and R_e is the radius of Earth. The general solutions to the Laplace equation are the Lamb waves in the Bessel function of a decaying order (lower impact for higher order BESSEL FUNCTIONS) as well as other propagating damped wavefunctions (*also see* **HOUGH EQUATION, LAMB WAVES, and BRUNT-VÄISÄLÄ BUOYANCY FREQUENCY OF THE ATMOSPHERE**) (see Figure T.34).

Figure T.34 Earth's thermosphere.

Thermostatistics

[thermodynamics] Classical THERMODYNAMICS defining equilibrium states. Also known as “highest-entropy” PHYSICS.

Thévenin, Léon Charles (1857–1926)

[electronics] Electrical engineer from France. The circuit theory EQUIVALENCE PRINCIPLE as derived by Léon Thévenin in 1883 was apparently independently derived by HERMANN VON HELMHOLTZ (1821–1894) in 1853. The Thévenin theorem is cited more frequently than the Helmholtz theorem (see [Figure T.35](#)).

Figure T.35 Léon Charles Thévenin (1857–1926).

Thévenin's theorem

[electronics] The combination of several supplies with independent EMF (electromotive force; electrical potential) and any combination of circuit ELEMENTS all between two terminal poles is equivalent to a single EMF in series with a single equivalent impedance between the same two poles. The Thévenin's theorem was described by LÉON CHARLES THÉVENIN (1857–1926). The value of the equivalent EMF source is the potential difference measured between the two terminals when the current is zero and the equivalent impedance is the same as the impedance measured when the equivalent EMF is zero (*also see* **KIRCHHOFF'S LAW**) (see [Figure T.36](#)).

Figure T.36 Thévenin's theorem.

Thick lens

[optics] Lens with a separation between the two surfaces on the optical axis that can result in the formation of an IMAGE within the LENS material. The ray shaping is described by the LENS MAKER'S EQUATION (see [Figure T.37](#)).

Figure T.37 Thick lens configuration and derivation of lens equation.

Thin lenses, combinations of

[general, optics] In practice, this describes an optical device that does not form an IMAGE inside the transparent object. The thin-lens equation describes the formation of an image at DISTANCE “ i ” from the LENS with respect to the object at DISTANCE “ o ” with respect to the radius of curvature of the incident surface (R_1) and the emerging surface (R_2), both taken with respect to the center of the lens with index of refraction n_2 as $(1/i) + (1/o) = [(n_2 - n_1)/n_1][(1/R_1) - (1/R_2)] = (1/f) = P$, where f represents the focal length of the lens, n_1 the index of refraction for the medium outside the lens, and P the power of the lens in diopters. A concave lens surface will result in a negative radius of curvature for that surface (*also see LENS EQUATION and THICK LENS*). Combinations of thin lenses will have a focal length that is the reciprocal sum of the individual focal lengths: $(1/f_{\text{tot}}) = +(1/f_1) + (1/f_2) + \dots$ (see [Figure T.38](#)).

Figure T.38 Thin lens configuration and image formation.

Third law of thermodynamics

[thermodynamics] See THERMODYNAMICS, THIRD LAW.

Thixotropic liquid

[fluid dynamics] Fluid with a decreasing APPARENT VISCOSITY as a function of time while under a constant shear rate.

Thomas precession

[atomic, relativistic] Correction factor to the ENERGY shift in the spectral FINE STRUCTURE (primarily for the HYDROGEN ATOM) related to the ORBITAL ANGULAR MOMENTUM, with magnitude $\frac{1}{2}$ (named after Llewellyn Hilleth Thomas [1903–1992] based on his 1926 publication) with respect to the influence of a MAGNETIC FIELD ($\vec{B}$) on the MAGNETIC MOMENT ($\vec{\mu}_{\text{mag}}$) expressed by $\Delta E = -\vec{\mu}_{\text{mag}} \cdot \vec{B} = (Ze^2\hbar^2/8\pi\epsilon_0c^2m_e^2)r^{-3}$, where r^{-3} is the expectation for the location r , which can be considered the BOHR RADIUS (n^2a_0) under nonrelativistic conditions, $e = 1.60217657 \times 10^{-19}$ C the electron charge, Z the PROTON number (atomic number), $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34}$ m²kg/s the PLANCK'S CONSTANT, c the speed of LIGHT, m_e the electron mass, and $\epsilon_0 = 8.85419 \times 10^{-12}$ C²/Nm² the permittivity of free space. The correction is based on the fact that a horizontal spin axis (e.g., top with “circumference” equivalence for atom) will be thrown off balance when a mass is added on one side of the ring. The process can take place during the L - S COUPLING (orbital angular momentum coupled to SPIN momentum; referred to as the relativistic spin–orbit effect), providing a torque on an electron that has its spin “flipped.” The applied torque will provide a PRECESSION analog to the LARMOR PRECESSION.

Thompson, Benjamin, Sir (1753–1814)

[general, thermodynamics] COUNT RUMFORD. Physicist from the United States. Ben Thompson had a passion for explosives and gunpowder, which led him to work on thermodynamic concepts, experimentally deriving the SPECIFIC HEAT for several substances. His efforts also applied to the THERMAL CONDUCTIVITY of gasses, or better, indicating the lack thereof (see [Figure T.39](#)).

Figure T.39 Sir Benjamin Thompson (1753–1814). Painting by Thomas Gainsborough 1783.

Thomson, George Paget, Sir (1892–1975)

[atomic, general, nuclear] Physicist and Nobel Laureate from Great Britain. George Thomson and CLINTON JOSEPH DAVISSON (1881–1958) shared Nobel Prize for their verification of the DE BROGLIE WAVELENGTH during electron–electron diffraction (see [Figure T.40](#)).

Figure T.40 Sir George Paget Thomson (1892–1975). (Courtesy of Nobel Foundation, Stockholm, Sweden.)

Thomson, Joseph John (1856–1940)

[atomic, energy, general, nuclear, quantum] Physicist from Great Britain. J.J. Thomson constructed a VACUUM tube to investigate the nature of CATHODE RAYS, and this resulted in the discovery of the electron in 1897, also based on the findings by his colleague, the French scientist, JEAN BAPTISTE PERRIN (1870–1942). The electron was the first verified subatomic PARTICLE. Thomson also invented the MASS SPECTROMETER. Thomson experimentally showed the deflection of a charged particle with charge e , smaller than an ATOM, moving with velocity v with mass m_e under the influence of an external electric field ($\vec{E}$) applied by two charged plates with length L , along with a MAGNETIC FIELD ($\vec{B}$) applied parallel to the orientation of the plates. The deviation in DISTANCE from the central axis and the axis of incidence is expressed as $e/m_e = 2y\vec{E}/L^2\vec{B}^2$, due to the large deflection the mass of the charged particle had to be less than the known mass of the hydrogen ion (H^+), by a factor 1836, and hence the mass had to be equally smaller and was thus recognized as the first subatomic particle, later identified as the electron. In 1899, Thomson further detailed his discovery with the PHOTOELECTRIC EFFECT. The work by Thomson inspired the charge qualification set up by ROBERT ANDREWS MILLIKAN (1868–1953) with the “oil-drop” experiment. Robert Millikan also further refined the photoelectric effect and defined it mathematically in 1914–1915. J.J. Thomson dedicated a great deal of his time on the essential characteristics of the cathode ray and

discovered that the ray was not equivalent to electromagnetic RADIATION with a much slower propagation velocity in 1894 (see [Figure T.41](#)).

Figure T.41 Joseph John Thomson (1856–1940).

Thomson, William (1824–1907)

[general, thermodynamics] Scientist from Scotland, Great Britain. Generally referred to as Lord Kelvin (see **KELVIN** [**LORD KELVIN**; **1ST BARON KELVIN**]).

Thomson atom

[atomic, general] Even though **JOSEPH JOHN THOMSON** (1856–1940) revealed the existence of the electron, there was ample prior work indicating a charge distribution in the **ATOM**. The electronic force description by **CHARLES-AUGUSTIN DE COULOMB** (1736–1806) was inconclusive, and the follow-up remarks by the mathematician from Great Britain, **SAMUEL EARNSHAW** (1805–1888) in 1831 [**EARNSHAW'S THEOREM**], stating that an inverse square law does not create an equilibrium condition unless the charges are in **MOTION**, led to the atomic model produced by J.J. Thomson in 1903. Additional contributions by **JEAN BAPTISTE PERRIN** (1870–1942) in 1901 and **LORD KELVIN** (1824–1907; **WILLIAM THOMSON**) in 1902 provided the building blocks of the “**RAISIN-PUDDING ATOM**” published in 1903. The incorporation of the full impact of Earnshaw's statement by **ERNEST RUTHERFORD** (1871–1937), eighty years later, did not happen until

1911 when the atomic model with a NUCLEUS surrounded by electrons in ORBITS like planets around the SUN was adopted. The Rutherford “planetary” model still provides the best description for all relativistic and nonrelativistic atomic phenomena (see [Figure T.42](#)).

Figure T.42 Thomson atom model.

Thomson scattering

[atomic, nuclear] SCATTERING of the CATHODE ray “particles” that interacted with the “AETHER,” dissociating the cathode ray from electromagnetic RADIATION as investigated by JOSEPH JOHN THOMSON (1856–1940) in the period 1895–1897 (see [Figure T.43](#)).

Figure T.43 Thomson scattering.

Thorium radioactive series

[atomic, nuclear] Thorium DECAY is used to identify one of three kinds of decay, next to radium or uranium decay, and the ACTINIUM decay families. The family indication represents the fact that the end product of these three series of decay is a different stable ISOTOPE of lead. Thorium-232 is abundantly available in

nature, and itself produces radon, a radioactive GAS found in the basement of many houses (*see* DECAY CHAIN) (*see* Figure T.44).

Figure T.44 Thorium.

Thorndike, Edward M. (1906?–)

[general] Physicist from the United States, who in 1932 in collaboration with Roy J. Kennedy, experimentally refuted the AETHER–wind contraction theorem postulated by ALBERT EINSTEIN (1879–1955). Their means of experimentation involved a modified Michelson–Morley INTERFEROMETER and confirm the special relativity aspects of the phenomenon.

Three Laws of planetary motion

[astro, general] Laws introduced by JOHANNES KEPLER (1571–1630) based on the experimentally derived data from TYCHO BRAHE (1546–1601). The first law states that planets move in elliptical ORBITS around the SUN, not in circular orbits as generally assumed (in practice the ellipse is not far from a circle, but the mechanical impact is crucial). The SECOND LAW states that the orbit around the Sun for each PLANET within incremental equal time frames demarcates equal areas, though with different chord lengths or arcs.

T

The diagram illustrates an elliptical orbit with the Sun at one focus. Earth is shown at two positions: perihelion (left) and aphelion (right). The semi-major axis is labeled a , the distance from the Sun to Earth at perihelion is R_p , and at aphelion is R_a . The distance from the Sun to the opposite focus is ea . The diagram also shows the Sun-Earth ratio "not" to scale.

Labels in the diagram include:

- $R_a = a(1 + e)$
- $R_p = a(1 - e)$
- Sun-Earth ratio "not" to scale
- Aphelion
- Opposite focus of ellipse
- e : Eccentricity of ellipse
- a : Semi major axis of ellipse
- Perihelion

- (a) All planets move in elliptical orbits, with the Sun at one focus

[illegible]

- (b)

Square of orbital period: $T^2 = \frac{4\pi^2}{GM} a^3$; a the planetary orbital radius (average)

- (c) The third law is derived from the law of gravitation. Sir Isaac Newton
Kepler's third law to base his law of gravitation on.

Figure T.45 Kepler's laws of planetary motion (a) first law, (b) second law, and (c) third law.

Throttle

[fluid dynamics, thermodynamics] PIPE segment with initial sharp decrease in CROSS SECTION in the direction of flow leading up to an ORIFICE, followed by a discontinuous increase to the original cross-sectional area. The function of the throttle is to introduce TURBULENCE at the discontinuity and facilitate a pressure drop. The general purpose of the throttle is to control the pressure drop between the inlet and output of a pipe segment. In certain cases, the orifice is adjustable in cross section, in which case it is called a throttle VALVE. The throttle valve has for instance been used in carburetor-controlled engines to regulate the flow of gasoline and hence control the revolutions of an INTERNAL COMBUSTION ENGINE and thus influence the velocity of movement for the automobile (*also see VENTURI*) (see [Figure T.46](#)).

Figure T.46 Throttle.

Thrust

[fluid dynamics] Push force. The push force can result from a jet ENGINE or a PROPELLER. The thrust force from a propeller can be defined as $F_T = (\pi/4)D^2\rho\Delta U[U + (\Delta U/2)]$, with D the propeller diameter, U the incoming flow velocity, and ΔU the increase in flow velocity due to the propeller action, assuming constant and equal pressure before and after the propeller. This principle applies in approximation both to airplane and boat PROPULSION. Alternatively, the thrust from a jet engine is defined by the impulse resulting from the combustion, measured by the ejected quantity of molecules resulting from the JET explosion, in which the bulk mass of molecules (m) is expelled at a high time averaged velocity over the diameter of the jet engine while the plane is in MOTION ($\vec{v}$), providing a momentum $\vec{p} = m\vec{v}$. The impulse force is now $\Sigma F = dp/dt = m(\partial\vec{v}/\partial t) + \vec{u}(\partial m/\partial t)$, note that mass is expelled and the mass rate of ejection is linked to the DENSITY (ρ) as $dm/dt = \rho Av$, where A is the CROSS SECTION of the output flow; $\vec{u}$ is the flow velocity with respect to the reference frame of the plane. Hence the thrust is provided by the expelled exhaust

$\vec{F}_T = \vec{u} \left(\partial m / \partial t \right)$. Note that the same principle applies to opening a fire extinguisher while sitting on a chair (see [Figure T.47](#)).

Figure T.47 Thrust.

Thyatron

[atomic, electronics, nuclear] ELECTRON TUBE design that applies a grid structure to the gas DIODE rectifier. The introduction of the GAS (e.g., argon, mercury vapor, or xenon) reduces the voltage BARRIER, hence increasing the efficacy as a RECTIFIER. Applying a variable potential (ranging from negative to positive) as positioned between the CATHODE and the ANODE regulates the electron and ION flow across the tube. The grid may also provide a means of deionization for the gas, with time frames ranging from 10 to 1000 μ s, the shortest time with hydrogen as the facilitating gas. In the 1960s, the thyatron has been replaced by the THYRISTOR. The thyatron cannot provide amplification.

Thyristor

[electronics] SOLID-STATE (semiconductor) switch. Some thyristors have photosensitive characteristics.

Tidal breathing

[biomedical, fluid dynamics] The periodic and repetitive inhalation and exhalation of GAS in and out of the lungs respectively under stable boundary conditions, no exercise and under normal pressure and oxygen SATURATION. Some of the parameters associated with tidal breathing and derived parameters are expiratory reserve volume, functional residual capacity, INSPIRATORY CAPACITY, INSPIRATORY RESERVE VOLUME,

RESIDUAL VOLUME, TIDAL VOLUME, total lung capacity, and vital capacity. All the breathing parameters can be determined by spirometry (see RESPIRATION) (see Figure T.48).

Figure T.48 Tidal breathing as an integral aspect of the respiration.

Tidal forces

[general, geophysics, mechanics] Forces that influence the DYNAMICS of the earth's surface water. Atmospheric flow, as well as EARTH'S CRUST, is primarily the result of gravitational attraction from the MOON and the SUN. The gravitational force is a function of the DISTANCE (r) between two or more bodies of mass (m_i), which can be LIQUID segments, expressed as $\vec{F}_g = G(m_1 m_2 / r^2) \vec{e}_r$, where $\vec{e}_r$ represents a unit vector in the direction of the connecting line between the two mass segments, and $= 6.67259 \times 10^{-11} \text{ Nm}^2 / \text{kg}^2$ the gravitational constant. Taking one of the masses as a solid distant object (M) influencing the attraction on a volume of liquid on EARTH will create an incremental drop in GRAVITATIONAL ACCELERATION ($\vec{a}_g$) with increasing distance (Δr) on the curvature of the face of the PLANET, expressed by the Maclaurin series as $\vec{a}_g = -G(M/r^2) \vec{e}_r \pm 2G(M/r^2)(\Delta r/r) \vec{e}_r \mp 3G(M/r^2)(\Delta r/r)^2 \vec{e}_r \pm \dots \mp \dots$. The gravitational force exerted by the moon's angular momentum on the earth's crust is gradually slowing down the earth's rotation, at a rate of $2.5 \times 10^{-9} \text{ s/day}$. The tidal force is providing a nonuniform force on a large body, specifically when the body is free to move with respect to its "host." Since GRAVITY obeys the inverse square law, the attraction will be greatest at the closest proximity on a curved surface facing another object. The gravitational tides on the earth's crust add to the centripetal forces of rotation to provide an elongation of the sphere, converting it into an ellipsoid. Based on the relative size and distance between the influences from the Sun and the

Moon, the sun's effect on the tides is approximately 45% that for the Moon, depending on the location of the Earth in its elliptical orbit and proximity to the Sun (see [Figure T.49](#)).

Figure T.49 Tidal forces. Influence of the position of both the Sun and the Moon of the tides by means of gravitational attraction on the liquid surface that can move freely.

Tidal motion

[general] Primarily observed for the earth's surface water. The oceans will be attracted to the MOON due to the gravitational interaction between the LIQUID mass and the mass of the Moon. The water surface closet to the Moon will be attracted with the greatest force, causing the highest elevation with respect to the average sea level (in the absence of CIRCULATION and external gravitational attraction). Water on the opposite side of the EARTH will experience attraction that will lower the water level with respect to "sea level" (see [Figure T.50](#)).

(a)

(b)

Figure T.50 (a,b) Tidal motion.

Tidal volume

[biomedical, fluid dynamics] (TV) During normal TIDAL BREATHING, the volume of inspired and expired AIR from the lungs. Tidal volume and other tidal breathing parameters can be measured with a spirometer (see Figure T.51).

Figure T.51 Tidal volume.

Tidal waves

[fluid dynamics, geophysics] The small AMPLITUDE oscillation in a LIQUID with a free surface induced by GRAVITY. Tidal waves have an elegant solution to the WAVE EQUATION. Tidal waves can also be referenced as CANAL WAVES. In zero-order approximation, the wave equation for the surface wave can be treated as a wave traveling with no deformation in the surface contour. The Lagrange approach for solving the displacement uses the kinetic ENERGY (E_k) derived from the surface matrix of n coordinates (q_n) that vanish at equilibrium ($q_1 = q_2 = q_3 = q_4 = \dots = q_n = 0$), with respective velocities $v_i = \dot{q}_i = \partial q_i / \partial t$ described as $E_k = (1/2) \{ c_{11} \dot{q}_1^2 + c_{22} \dot{q}_2^2 + \dots + c_{nn} \dot{q}_n^2 + \dots + 2c_{12} \dot{q}_1 \dot{q}_2 + 2c_{23} \dot{q}_2 \dot{q}_3 + \dots + 2c_{n,n-1} \dot{q}_n \dot{q}_{n-1} \}$. The potential energy stored in the raised water level is similarly defined as $U_p = (1/2) \{ c_{11}' q_1^2 + c_{22}' q_2^2 + \dots + c_{nn}' q_n^2 + \dots + 2c_{12}' q_1 q_2 + 2c_{23}' q_2 q_3 + \dots + 2c_{n,n-1}' q_n q_{n-1} \}$. The Lagrange equation for the movement of the respective coordinates now becomes $(d/dt)(\partial E_k / \partial \dot{q}_i) - (\partial E_k / \partial q_i) = -(\partial U_p / \partial q_i) + D_i$, where D_i are the coefficients of displacement in the direction normal to the undisturbed surface, $i = 1, 2, 3, \dots, n$, describing the matrix of surface displacement as $D_1 \Delta q_1 + D_2 \Delta q_2 + \dots + D_n \Delta q_n$. This yields $D_i = c_i \ddot{q}_i + c_i' q_i$, where $\ddot{q}_i = \partial^2 q_i / \partial t^2$. The "forced" OSCILLATION solution now becomes $q_i = C_i / (c_i' - \tau_\pi^2 c_i) \cos(\tau_\pi t + \epsilon_\pi)$, where the wave has a period

$2\pi/\tau_\pi$, with $\tau_\pi^i = \sqrt{c_i^l/c_i}$, with C_i the coefficients for the simple harmonic solutions ($Q_i = C_i \cos(\tau_\pi t + \epsilon_\pi)$). Also referred to as Tidal Bore (see Figure T.52).

Figure T.52 Tidal bore, captured in Sumatra. (Courtesy of photographer Muhtar Sanusi and Antony Colas; www.bonosurf.com.)

Tide-generating forces

[fluid dynamics, geophysics] The gravitational attraction of the MOON in an orbit around the EARTH exerts a force on both the Earth and the free-flowing liquid on the surface, creating TIDAL WAVES. In large bodies of water (ocean and sea), this creates tidal waves. On the ebb and flood aspect of the main bodies of water, the rivers will drain or fill, creating canal tidal waves. The mass (m_{moon}) of the Moon at a variable DISTANCE (d_{moon}) from the Earth exerts a force that is dependent on the location on the earth's surface (with radius: r_{earth}) as well as the moon's zenith (the ANGLE with respect to a fixed meridian at longitude ϕ_{long} yields the ZENITH as a function of TIME (t) $\vartheta_{\text{moon}} = m_\omega t + \phi_{\text{long}} + f$, where ϕ represents the PHASE of the MOTION wavefunction and $m_\omega = r_{\text{earth}}\omega$, with ω the ANGULAR VELOCITY of the earth's revolution at a given location (P). The gravitational pull provides an ENERGY potential (U_Ω) that is linked by the gravitational constant (γ_{grav}) as $U_\Omega = (3/2)(\gamma_{\text{grav}} m_{\text{moon}} r_{\text{earth}}^2 / d_{\text{moon}}^3)[(1/3) - \cos^2(\vartheta_{\text{moon}})]$. The potential provides the horizontal acceleration vertically beneath the Moon in the tangential direction as $a_{//} = \partial U_\Omega / r_{\text{earth}} \partial \vartheta_{\text{moon}} = (3/2)(\gamma_{\text{grav}} m_{\text{moon}} r_{\text{earth}} / d_{\text{moon}}^3) \sin(2\vartheta_{\text{moon}})$; note that the Earth's gravitation (g) is linked to the mass of Earth (m_{earth}) to yield: $g = \gamma_{\text{grav}} m_{\text{earth}} / r_{\text{earth}}^2$. Similarly the SUN (mass: m_{sun} ; distance: d_{sun}) exerts a force that influences the tides in a similar fashion (i.e., presenting a cumulative effect). Now the equation of motion for the displacement (ξ) of the surface of the LIQUID with respect to "sea level," that is, the earth's surface): $\partial^2 \xi / \partial t^2 = v^2 (\partial^2 \xi / r_{\text{earth}}^2 \partial \phi_{\text{long}}^2) - (3/2)(\gamma_{\text{grav}} m_{\text{moon}} r_{\text{earth}} / d_{\text{moon}}^3) \sin(2[m_\omega t + \phi_{\text{long}} + \phi])$, where v is the speed of WAVE propagation. The AMPLITUDE A_{tidal} (i.e., the maximum range of low to high water during the semidiurnal period (T_{diurnal}) of the wave: $T_{\text{diurnal}} = 2\pi r_{\text{earth}} / m v$, with $n: 1 - \infty$) is represented for a uniform river basin floor bed as $A_{\text{tidal}} = r_{\text{earth}} [(3/2)(\gamma_{\text{grav}} m_{\text{moon}} r_{\text{earth}} / d_{\text{moon}}^3) / g] = r_{\text{earth}} (f/g)$. The "free" OSCILLATION solution to the wave equation under the influence of the Moon can be expressed under the FOURIER THEOREM as $\xi = -(1/4)[f r_{\text{earth}}^2 / (v^2 - m^2 r_{\text{earth}}^2)] \sin(2[m_\omega t + \phi_{\text{long}} + \phi])$, yielding for the physical perpendicular surface displacement: $\chi = -(1/2)[A_{\text{tidal}} v^2 / (v^2 - m^2 r_{\text{earth}}^2)] \cos(2[m_\omega t + \phi_{\text{long}} + \phi])$. Keeping in mind that the depth of the river will place a limiting factor on the wave phenomenon, not to have the amplitude exceed the depth. At great depths (as what may be found in the far off-shore ocean), the tidal wave will be antiparallel, or in counterphase (see TIDAL WAVE and TIDAL FORCE).

Timbre

[acoustics, general] The **FREQUENCY SPECTRUM** associated with the **SOUND** produced by an instrument. Often referred to as the “**COLOR**” of the sound. The introduction of higher harmonics by the instrument design and the way the primary tones are generated (the way the instrument is played) influence the spectral power profile as well as the range/expanse of the spectrum. For instance, for a wooden instrument, the local **HUMIDITY** will affect the elastic modulus of the casing for the **REVERBERATION** produced by an oscillating string. The elastic modulus will affect the **VIBRATION AMPLITUDE** as a function of wavelength. The choice of material can be instrumental in defining the sound quality as is the functional geometric design (shape and material thickness, etc.). For instance, the construction and finish (e.g., varnish) will be crucial; a Stradivarius violin still catches the attention of the audience after more than 300 years of **AGE**. The Stradivarius name was known as a family instrument makers business during the seventeenth and eighteenth century, particularly famous was Antonio Stradivari (1644–1737) for his skills in design, material selection, and material preparation as well as assembly (see [Figure T.53](#)).

Figure T.53 Metal straight flute.

Time (t)

[general] Sequence of events placed in relative respect to each other. Early concepts of time were attributed to the solar night–day rhythm (circadian rhythm), which as divided into two 12 segments by the Egyptians approximately 3000 years ago, defining the 24 h day. Persian mathematics (i.e., Babilonia) had the number 60 as the base (*Note*: the French arithmetic has the number 24 as base), which influenced the later subdivision of the hour into 60 min introduced in the fourteenth century when keeping track of time became more feasible with mechanical devices. As more intricate and accurate time keeping devices were developed, the minute was divided in 60 s. In 1967 a formal definition of the second as the standard of time was defined by the Si as the duration of 9192631770 oscillations of the **RADIATION** from cesium ^{133}Ce , the introduction of the **ATOMIC CLOCK**. The atomic clock in Boulder, Colorado, the United States is approximately 15.5 nanoseconds faster than the atomic clocks in Washington, DC, or Paris, France, which was indicated by **ALBERT EINSTEIN** (1879–1955) that time **MEASUREMENT** in this manner depends on **GRAVITY**. Early Babylonian and Egyptian time-keeping records used water flow and syphons as far

back as the sixteenth century BC. Additional early mechanisms of measuring used the Sun in the form of sundials (see [Figure T.54](#)).

Figure T.54 (a) Ancient water clock and (b) historic sun dial.

Time dilation

[atomic, general, relativistic] See **DILATION**.

Time perturbation, colliding black holes

[astrophysics, general] In 1916 ALBERT EINSTEIN (1879–1955) predicted that under the concept of general relativity, the space-time CONTINUUM could be disrupted, making the UNIVERSE “ring.” At this point of time, no confirmed observations are documented for collisions of BLACK HOLES, nor has the time RIPPLE been measured. Based on theoretical considerations and the composition of the universe as we currently understand it, there may be small probabilities that black holes will collide in the next several million years, two black holes in the QUASAR PG 1302-102 can indeed merge. The two black holes are at approximately 3.5 billion light-years DISTANCE from our SOLAR SYSTEM. Another supposed double black-hole galaxy is NGC 6240, which is located at 140 million light-years from our solar system. This provides a better opportunity for two black holes, within the same GALAXY, to merge. So far the predictions indicate that this merger of two black holes in the NGC 6240 galaxy will at least not happen for another 100 million years. The MILKY WAY itself is supposedly meeting up with the ANDROMEDA GALAXY in several billion years from now, as we approach at 120 km per SECOND. In general, when galaxies merge, the central black holes of the respective galaxies will be placed in orbit with each other. Several known galaxies have been shown to have a BLACK HOLE at its center. The Milky Way has a confirmed central black hole at a distance from our solar system of approximately 28,000 light-years (*Note:* estimate diameter of the Milky Way is 100,000 light-years). The anticipated perturbations in the spacetime continuum (e.g., ripples in time) resulting from black-hole collisions are

represented by “GRAVITATIONAL WAVES.” The Einstein Equations elegantly allow the unification of space and time into a format known as “SPACETIME.” When trying to solve for impact on either space (GRAVITY) or time the Einstein equations will need to be decomposed so that mathematical approach reverts to the “Cauchy problem” (mathematician from France: BARON AUGUSTIN-LOUIS CAUCHY (1789–1857)). During a collision of two black holes in approximation roughly 0.1% of the mass of the merged system is “radiated away” as gravitational waves. The impact on “pure time” can be imagined in the SPACETIME representation by means of expression of points with coordinates of both space and time. Slices in the SPACETIME of constant time will intersect with spatial coordinates. The lapse in “proper time” (as we live it) can be derived using the decomposition of the EINSTEIN EQUATIONS in the Cauchy problem version specific to solving partial differential equations on a hypersurface in a multidimensional domain. The Cauchy problem consists of finding the SOLUTION u of the differential equation for the functions f_k on the surface S of order m that satisfies $\partial^k u(x)/\partial n^k = f_k(x)$ $\{k = 1, 2, 3, m-1\}$, where n is the normal vector to the surfaces, which is known as the Cauchy data, under the boundary condition $u(x) = f_0(x)$. Under SPECIAL RELATIVITY, the spacetime continuum is considered to be “flat,” meaning no change in time associated with changes in gravitational MOTION. In this case, the interval (ds) between two points in space and time is defined as $x^a = (t, x^1, x^2, x^3) = t \begin{pmatrix} 1 \\ x^i \end{pmatrix}$, with concurrent changes $x^a + dx^a = (t + dt, x^i + dx^i)$, which can be rewritten using the PYTHAGOREAN THEOREM as $(ds)^2 = -dt^2 + (dx^1)^2 + (dx^2)^2 + (dx^3)^2 = \sum_{a,b} \eta_{ab} dx^a dx^b$. The matrix is normalized by means of the Minkowski metric TENSOR (Russian mathematician HERMANN MINKOWSKI (1864–1909)): η_{ab} with diagonal $\eta_{ab} = \text{diag}(-1, 1, 1, 1)$. In this interval, the time (τ) is defined by means of proper time under the condition $d\tau^2 = -ds^2$, that is, less than zero. Under general relativity, specifically when “SPACETIME” is curved, the Minkowski metric tensor changes to provide the tools for $(3 + 1)$ decomposition (representing the Cauchy problem) as g_{ab} ; $ds^2 = \sum_{a,b} g_{ab} dx^a dx^b$. The $(3 + 1)$ decomposition constraints the gravity fields (in the EINSTEIN EQUATIONS) for every instance of time, and allows for an additional time perturbation of the gravitational fields, thus splitting the SPACETIME into space and time. In the $(3 + 1)$ decomposition SPACETIME can be considered to be foliated into slices defined by constant time coordinates. In the $(3 + 1)$ decomposition, spacetime “points” are connected by vector t^a , using a time vector that stands normal to the SPECIAL RELATIVISTIC space, defined as n^a . The SPACETIME slices will be separated by dt , defined by a lapse function α_{lapse} . The “lapse function” relates to “proper time” (as we live it) in SPACETIME in the displacement (dx^a) between two points $[A^{x^i, t}$ and $B^{x^i + dx^i, t + dt}]$ written using the Pythagorean theorem as $ds^2 = -\alpha_{\text{lapse}}^2 + \sum_{i,j} \gamma_{ij} (dx^i + \beta^i dt)(dx^j + \beta^j dt)$, where γ_{ij} is a quantity defining the spatial separation between the two SPACETIME slices. Under these conditions, the curvature in SPACETIME is defined by the time derivative of the spatial metric γ_{ij} to yield the extrinsic curvature K_{ij} (see Figure T.55).

Figure T.55 Geometric representation of space–time described under the conditions of curved space. The transition between two points in the spacetime matrix is described by general relativity methods.

Timocharis

[astrophysics, general] Fourth century BC, Greek scientist and astrophysicist. Together with ARISTYLLUS, they documented the first list of visible fixed stars.

Tip angle

[energy] **ANGLE** of airplane **WING** with a horizontal reference plane, with the vertical plane in which the **PROPELLER** rotates (ship, wind **TURBINE**). The tip angle changes during the take-off for an airplane, and can be adjusted for a wind turbine or old-fashioned windmill to adjust for influences generated by the wind direction, wind velocity, as well as desired performance. The tip angle for a plane obtaining a cruising altitude, steady-state flight, is also referred to as the tip-settling angle. For a propeller (airplane engine, ship/motor-boat, and wind turbine), there is an angle associated with the performance (efficacy and efficiency). Also referred to as the turbine blade angle (see [Figure T.56](#)).

Figure T.56 Tip angle of an airplane wing.

Tissue characterization

[acoustics, biomedical, imaging] Mechanism-of-action applied in acoustic (**ULTRASOUND**), optical, magnetic (**MRI**), **X-RAY**, or positron emission (**PET**) imaging to identify the characteristic properties that allow for discrimination between tissue functionality, tissue composition, and tissue density. The parameters used for characterization can be any of the following with their respective potential for identification: **FREQUENCY SPECTRUM** (tissue type or stage of development: collagen/fat/bone; **METABOLIC ACTIVITY**; general subjective health: “you don’t look so good”); attenuation (elastic modulus, density, phase [liquid/solid]); and refraction/reflection (boundary detection). Under certain circumstances, a “tag” is required to assist in the characterization process; for **PET**, this tag is fluorine-18-fluorodeoxyglucose, which acts as **GLUCOSE** but has a specific positron **EMISSION SPECTRUM** that can be acquired as a function of location hence revealing the local metabolic activity. These imaging methods can be applied *in vivo*. The other imaging technique performed *ex vivo* is optical microscopy. Optical imaging generally requires staining with dyes and chemicals for visible or fluorescent recognition of **CELL** types in order to screen for deviations from the norm. One optical technique that can provide *in-vivo* imaging is **OPTICAL COHERENCE TOMOGRAPHY**, which can apply all the optical features (**PHASE**, wavelength, **MAGNITUDE**, and combinations of factors to reveal physiological features next to anatomical features). Another relatively new imaging technique is photoacoustic imaging, combining

the acoustic and optical modalities to reach deeper than standard optical imaging and provide acoustic RESOLUTION (see Figure T.57).

Figure T.57 Visual rudimentary characteristics of the appearance of tissue under (left) bacteria compared to tonsillitis of the throat and (right) viral versus bacterial infection diagnosis.

Titanium

[biomedical, mechanics, solid-state] Chemical ELEMENT, metal: $^{48}_{22}\text{Ti}$. Titanium was discovered in 1791 by William Gregor (1761–1817); it is a very strong and light-weight METAL with a silver COLOR with a relatively high MELTING POINT (1941K, compare to 1811K for IRON; 1357 K for copper). Titanium has excellent biocompatibility, no toxic effects, and is resistant to the acidic nature for decades of functional use. Titanium is used in durable devices such as JET engines, missiles, automotive/motorcycle, orthopedic implants, and implantable defibrillators/pacemakers. Titanium can form alloys with several other metals: iron, aluminum, vanadium, and many more. Titanium is an excellent CONDUCTOR of electrical current. Titanium alone does not function well as a biological ELECTRODE due to POLARIZATION effects. The use of Titanium for electrode material will result in a gradual loss of signal AMPLITUDE as a result of the localized charge accumulation.

Toepler, August Joseph Ignaz (1836–1912)

[biomedical, energy, general, optics] Physicist from Germany (Prussian Empire) who made several discoveries related to electrostatic behavior next to investigations in fluids. In his analysis of FLUID flow and associated shock waves, he applied Foucault's knife-edge test for TELESCOPE mirrors (1864) as a mechanism for imaging. He is credited with describing the heat-induced BIREFRINGENCE in materials in 1894. The imaging mechanism under the birefringence discovered by August Toepler was characterized

as SCHLIEREN IMAGING. Schlieren imaging has only had limited applications so far, but is gaining interest (see [Figure T.58](#)).

Figure T.58 August Joseph Ignaz Toepler (1836–1912). (Courtesy of Österreichische Zentralbibliothek für Physik 1908.)

Tokamak Fusion Reactor

[general] REACTOR accelerator designed for NUCLEAR FUSION based on a close to ideal toroidal MAGNETIC FIELD. The name is a Russian acronym that loosely translates into “toroidal chamber with magnetic coils.” The toroidal confinement provides the boundary conditions for theoretical stability of a PLASMA in equilibrium. The specific plasma confinement is provided by an additional poloidal magnetic FLUX in the toroid, which provides conservation of the canonical angular momentum. The toroidal canonical angular momentum conservation results in a characteristic closed orbit. The plasma is initially created as the result of ohmic current interactions with an ionizing gas. The plasma is confined by “scraping off” the outer layer using a diverter separatrix, preserving the D-shaped tokamak plasma. The tokamak principle and prototype were constructed by the physicists from Russia (USSR: Union of Soviet Socialist Republics; in short Soviet Union) Igor Tamm (1895–1971) and Andrei Sakharov (1921–1989), in the 1950s (see [Figure T.59](#)).

Figure T.59 Image of the Tokamak Fusion Reactor design.

Tomographic slices

[biomedical, imaging] In order to view the content of any three-dimensional construction, one will require a SLICE to observe the pertinent information within the structure. There are several ways of slicing a tomographic reconstruction, primarily axial (a slice of the body on the axis of the body); coronal (a view of a plane that is parallel to the plane marked out by the extremities; arms and legs); and a sagittal view that carves the body from anterior to posterior, dividing left and right side of the body at various distances from the center (see [Figure T.60](#)).

Figure T.60 (a–e) Designation with respect to tomographic slice configuration. (e: Adapted from Prince, J.L. and Links, J., *Medical Imaging Signals and Systems*, Pearson Education, Upper Saddle River, NJ, 2006.)

Tomography

[acoustics, biomedical, electromagnetism, imaging] Two- or three-dimensional reconstruction of an IMAGE formed by probing line-of-flight radiation. Generally the source to detector correlation is on opposing sides of a circular band; the sensors are simultaneously collecting at multiple locations from within the same toroidal configuration. The RADIATION can be X-RAY, RADIONUCLIDE positron emission from artificially induced radioactive isotopes that generates the release of two perfectly opposite gamma ray photons (PET) and line-of-sight capture of radiofrequency RESONANCE signals induced by magnetic fields (MRI). An additional form of tomography uses geometric reconstruction based on the BACKSCATTER of LIGHT under optical coherence tomography (OCT), where the scanning pattern defines the extend of the two-dimensional outline, with the depth providing the third dimension. The depth of OCT probing is confined by the SIGNAL strength collected form depths of several micrometers from OPAQUE media (see [Figure T.61](#)).

Figure T.61 Tomography: (a) CAT scan of the brain; computer assisted tomography; imaging with X-ray and (b) three-dimensional rendering of the brain from acquired images slices.

Tomonaga, Sin-Itiro (朝永 振一郎) (1906–1979)

[general] Physicist from Japan. Sin-Itiro Tomonaga received the Nobel Prize in Physics in 1965 for his contributions to quantum PHYSICS theory, specifically quantum ELECTRODYNAMICS. He shared the Nobel Prize with RICHARD FEYNMAN (1918–1988) and Julian Schwinger (1918–1994). Sin-Itiro Tomonaga performed experimental verification of the pair creation of the PHOTON–electron pair in 1939, and worked closely with WERNER HEISENBERG (1901–1976) in Germany. On his return to Japan, he developed the theoretical definition of the MESON cloud around the NUCLEON. In 1942, he proposed the covariant field theory, in which the QUANTUM STATE was also relativistically covariant (see [Figure T.62](#)).

Figure T.62 Sin-Itiro Tomonaga (朝永 振一郎) (1906–1979). (Courtesy of University of Chicago Press, Chicago, IL.)

Tonicity

[biomedical, chemical] Expression of the OSMOTIC PRESSURE gradient across a SEMIPERMEABLE MEMBRANE (such as a CELL MEMBRANE) of two ionic/molecular solutions. Due to the fact that the cell membrane of most mammals is permeable to only a select few ions and molecules and highly diffusive to water, the changes in concentration of certain cellular constituents can result in the release or gain of water. The release of water as a result of OSMOSIS will result in cell shrinkage. Alternatively when the extracellular FLUID is diluted, the cell will gain water and will swell. A swollen cell will activate its sodium, potassium, and chlorine channels, resulting in an efflux primarily of K^+ and Cl^- due to the difference in mobility. This chemical exchange will not affect the MEMBRANE POTENTIAL, due to the opposite charge signs

involved. Both cell swelling and shrinking will dramatically impair the function of the cell, potentially resulting in cell death (see [Figure T.63](#)).

Figure T.63 Hypoxemia.

Tornado

[fluid dynamics, geophysics, mechanics, meteorology] Air-flow vortex of large proportions. Note that tornadoes are different from hurricanes, although hurricanes can *SPIN* off tornadoes. The rotation of a column of *AIR* can touch the surface while stretching out into cumulonimbus clouds, and on rare occasions may reach upward to the cumulus cloud portion of the *ATMOSPHERE*. Tornadoes form as a result of converging air masses from different directions, specifically the convergence of a cold and a warm airstream. The tornado is generally preceded by a rotation in the upper atmosphere that is observed in geological radar stations that observe the formation and precipitation of *RAIN* and snow clouds, at the level of cumulonimbus clouds. Tornadoes are also referred to as twisters or as cyclones and are found all over the world. The majority of tornadoes occur in what is known as Tornado Alley in the central part of the United States. Tornado Alley stretches from south to north starting in Texas, going through Oklahoma, Kansas, Nebraska, and North and South Dakota. The Tornado Alley gains its reputation from warm Gulf of Mexico air colliding with cold air from Canada and the Arctic. Tornadoes can have a diameter of over 75 m to close to 2 km. Small tornadoes travel slowly, at about 40 km per hour, whereas speeds up to 300 km per hour have been clocked for large tornadoes. A strong and destructive tornado is referenced as an F-5, whereas lower numbers are less potent. Tornadoes last from several minutes to, rarely, one hour. Due to Coriolis forces, tornadoes on the northern hemisphere turn counterclockwise and clockwise on the southern hemisphere. The F-scale is derived from Tetsuya Fujita (1920–1998) who designed the scale based

on anticipated or experienced destruction. The VORTEX phenomenon can LIFT entire houses of their foundation, and the accompanying pressure gradient will shatter most windows within its path and direct vicinity (see [Figure T.64](#)).

Torque (τ)

[general] The sum of the tangential components of the net LEVER force multiplied by the DISTANCE from the point of rotation to the point where the forces are applied, that is, the MOMENT ARM.

Torque is mathematically defined as $\vec{\tau} = \sum \vec{F} \times \vec{r}$. Torque resulting in clockwise rotation is positive, whereas counterclockwise rotation has a negative torque (see [Figure T.65](#)).

Figure T.65 Torque wrench with dial for indication of applied torque.

T

Torr

[general] Unit of pressure, equivalent to 1 Torr = 1 mmHg = 133.3 Pa on the MERCURY BAROMETER scale (see EVANGELISTA TORRICELLI [1608–1647]).

Torrey, Henry Cutler (1911–1998)

[atomic, imaging, nuclear] Physicist from the United States who contributed to the theoretical understanding of nuclear MAGNETIC RESONANCE. The work of Henry Torrey provided significant advancement of magnetic resonance imaging (MRI), in collaboration with EDWARD MILLS PURCELL (1912–1997) and ROBERT VIVIAN POUND (1919–2010), based on the earlier work of ISIDOR RABI (1898–1988) and FELIX BLOCH (1905–1983).

Torricelli, Evangelista (1608–1647)

[fluid dynamics, general, geophysics, meteorology]: mathematician and physicist from Italy, protégée of GALILEO GALILEI (1564–1642). Following in the footsteps of Galileo and his work with experimental observations on the “weight” of AIR (glass bulb), Torricelli realized the cause and effect in 1643. His work in COMMUNICATING VESSELS led to the construction of a device to measure the fluctuating pressure in the ATMOSPHERE with changing weather conditions, or better in anticipation of changing weather conditions. The TORRICELLI BAROMETER was confirmed and details were added by BLAISE PASCAL (1623–1662) in 1648. Torricelli lent his name to the TORR or mmHg (millimeter mercury) as a unit for pressure, mostly used for low pressure, whereas the PASCAL (Pa) is the recognized standard unit for pressure (see Figure T.66).

Figure T.66 Evangelista Torricelli (1608–1647).

Torricelli's barometer

[fluid dynamics] Barometer as introduced by EVANGELISTA TORRICELLI (1608–1647) around 1643 that consists of a GLASS tube inserted in a bowl of mercury. The tube is closed on the top, and the ATMOSPHERE provides a column of AIR resting on the surface of the mercury in the bowl, raising the mercury level. GALILEO GALILEI (1564–1642) had already determined that air has mass (weight), which led Torricelli to the correlation and derived the pressure resulting from a tall volume of air surrounding the globe as a function of weather conditions and altitude. The location-dependent pressure variability was derived in collaboration with BLAISE PASCAL (1623–1662) in 1648. The same principle was applied to measure BLOOD

pressure in 1726. The first recorded attempts to measure BLOOD PRESSURE are the work of the clergyman, astronomer, chemist, and botanist from Great Britain, Stephen Hales (1677–1761). The reverend Stephen Hales used a brass PIPE (one-sixth of an inch in diameter) connected to a narrow glass tube and attached it to the carotid artery of a horse to investigate what was ailing the dying animal. The tube was 12' 9" tall (388 cm) and the blood reached approximately 8 feet in height (2.44 m). Repeating his experiments for other locations and with other animals, he was able to provide a diagram of blood pressure distribution based on the ANATOMY and DISTANCE to the HEART for several animals and developed a system to apply this to humans as well. This fluid-dynamics system has considerable DAMPING and provides an average pressure value. For humans, Hales concluded a pressure of 7' 6" (apparently based on hypothesis), corresponding to a SYSTOLIC PRESSURE of 176 mmHg on "modern" standards. This type of MEASUREMENT was performed on humans by a French surgeon in 1820 providing the equivalent of 120 mmHg on the femoral artery when his patients had to have a LEG amputated. In 1876, the first SPHYGMOMANOMETER was developed that measures the corresponding blood pressure on the wrist by means of a balloon pressed against the radial artery (as connected to the brachial artery that is currently used to measure the blood pressure in the elbow). The wrist sphygmomanometer was developed by Karl Samuel Ritter Von Basch (1837–1905) from Czechoslovakia (now Czech Republic). In 1896, the Riva Rocci Sphygmomanometer was developed, which measures the blood pressure at the elbow and is the predecessor to the current state-of-the-art device. It was not until 1904 that the Russian army surgeon NIKOLAI KOROTKOFF (1874–1920) realized that closing off the brachial artery allowed for measuring the systolic versus DIASTOLIC PRESSURE using the fluttering sounds of blood rushing through a pinched blood vessel (KOROTKOFF SOUNDS) (see MERCURY BAROMETER, BLOOD PRESSURE, and NIKOLAI KOROTKOFF) (see Figure T.67).

Figure T.67 Torricelli barometer.

Torsion

[computational, general, mechanics] In mechanical ENGINEERING, this refers to the mechanical twisting of an object under the influence of an applied torque. The mechanical torsion is represented by the torque τ_T , defined by the shear stress in the twisted material on the outer surface (σ_s^*), the material properties imbedded in the torsion constant (J_τ), as a function of the DISTANCE of the farthest point out from the rotational axis of symmetry to the outer surface (r) expressed as $\tau_T = (J_\tau/r)\sigma_s^* = (J_\tau/\ell)G_\sigma\theta$, where G_σ is the shear modulus for the material and geometry (also referred to as the MODULUS OF RIGIDITY), θ the ANGLE OF

rotation/twist in the material with respect to relaxed state, and ℓ is the length over which the torque is applied. In ALGEBRA, the torsion characterizes the twisting of a moving reference frame around a curve. The torsion TENSOR ($T(\mathbf{X}, \mathbf{Y})$) defining the manner in which a moving frame is screwed around a state curve is described with respect to the vector fields $\mathbf{X}$ and $\mathbf{Y}$ as $T(\mathbf{X}, \mathbf{Y}) = \nabla_{\mathbf{X}}\mathbf{Y} - \nabla_{\mathbf{Y}}\mathbf{X} - [\mathbf{X}, \mathbf{Y}]$. In this notation, $[\mathbf{X}, \mathbf{Y}]$ represents the Lie bracket of vector fields, the Lie derivative $\mathcal{L}_{\mathbf{X}}\mathbf{Y} = \lim_{t \rightarrow 0} [((d\Phi_t^{\mathbf{X}})\mathbf{Y}_{\Phi_t^{\mathbf{X}}(x)} - \mathbf{Y}_x)/t]$, where $\Phi_t^{\mathbf{X}}$ represents the flow associated with the vector field, and $d\Phi_t^{\mathbf{X}} = \partial \hat{\Phi}^{\mathbf{X}} / \partial u^i$ is the tangent map derivative operator applied to the flow field, providing the linear map of the differential of $\Phi_t^{\mathbf{X}}$, $\hat{\Phi}$ the smoothed vector field $\Phi_t^{\mathbf{X}}$, and u the transform of x in the vector flowchart (see Figure T.68).

Figure T.68 Torsion.

Torsion wave

[fluid dynamics, general, mechanics] Under rotational agitation of a FLUID or solid, the harmonic perturbation will travel forming a torsion wave. For instance, the axle of a car is under continuous torsional forces that vary with time, hence creating a torsional wave, specifically the use of the torsion bar suspension. Another example is in the vertical agitating top-loader washing MACHINES (driven torsional OSCILLATION). The torsion wave (*also see DAMPED HARMONIC MOTION and FORCED VORTEX*) (see Figure T.69).

Figure T.69 Torsion wave. (Courtesy of Kay Wyatt.)

Torsional oscillations

[fluid dynamics, general, mechanics] Two prime examples of TORSION WAVE are for a hollow sphere filled with viscous LIQUID oscillating around its vertical axis and a sphere oscillating around its vertical axis surrounded by viscous liquid. The vertical agitating laundry washing machine found in the United States and Great Britain and other locations (different from the front-load washing machine) would be the cylindrically symmetric version for the spherical oscillation surrounded by a viscous liquid. The situation for the hollow sphere with radius R , oscillating at an ANGULAR FREQUENCY ω , that is filled with viscous liquid will have PARTICLE movement as a function of radius described by $\omega' = \left[\psi_1(br) / \psi_1(bR) \right] \omega$, where $b^2 = -(\sigma_\omega / \nu_{\text{kin}})$ represents the “functional” DISTANCE from the center on the rotating axis, $\nu_{\text{kin}} = \eta_{\text{kin}} / \rho$ the coefficient of KINEMATIC VISCOSITY (η_{kin} the kinematic viscosity, ρ the density), $\sigma_\omega = \nu_s k$ the angular velocity of rotational motion (ν_s the wave propagation velocity), and ψ_1 is the first-order spherical harmonic component. The general SOLUTION to the WAVE EQUATION, $(\nabla^2 + k^2)\phi(r, \theta, \varphi) = 0$, provides $\phi = \sum \{ A\psi_n(kr) + B\Psi_n(kr) \} r^n S_n$, where A and B are constants, k is the wavenumber, and S_n represents the surface harmonic of order n . The functions are linked to BESSEL FUNCTIONS ($J_k(\xi)$), of the order $\pm(1/2)(2m+1)$, as $\xi^n \psi_n(\xi) = \sqrt{[(\pi/2\xi) J_{n+(1/2)}(\xi)]}$; $\xi^n \Psi_n(\xi) = (-1)^n \sqrt{[(\pi/2\xi) J_{-n-(1/2)}(\xi)]}$, respectively $\psi_n(\xi) = 1/1.3 \dots (2n+1) \{ 1 - [\xi^2/2(2n+3)] + [\xi^4/2.4(2n+3)(2n+5)] - \dots \}$ and $\Psi_n(\xi) = 1.3 \dots (2n+1) / \xi^{2n+1} \{ 1 - [\xi^2/2(1-2n)] + [\xi^4/2.4(1-2n)(3-2n)] - \dots \}$. Due to the fact that the MOTION at the central axis (origin) is finite (no motion on the vertical axis) only the term $= A\psi_n(kr) r^n S_n$ is retained. The sphere will be suspended by the external axis. The angular velocity on the axis for the liquid within the sphere will need to be zero under consideration of ENERGY constraints. For the viscous liquid inside the rotationally oscillating sphere there are two situations: low- or high-viscosity medium. The high-viscosity case yields (the Stokes theorem): $\omega' = \left[\psi_1(br) / \psi_1(bR) \right] \omega = \omega \cos(\sigma_\omega t + \epsilon)$, where ϵ is the phase shift. Under these high-viscosity OSCILLATION conditions, the net torque (sometime also described as “couple”) is given as $\tau_F = (8/3)\pi\eta_{\text{kin}}R^3 \left[b^2 R^2 \psi_2(br) / \psi_1(br) \right] \omega$. In contrast, the low-viscosity case changes the boundary conditions to include more elaborate details: $2i\psi_n(bR) = [-(d/\xi d\xi)]^n (e^{i\xi}/\xi)$. The low-viscosity oscillation yields for the torque as a function of time $\tau_F = -(4/3)(\pi\rho R^5/\beta'\sigma_\omega) (d\omega/dt) - (8/3)\pi\eta_{\text{kin}}R^3(\beta'\sigma_\omega)\omega$, where the first term is an indication of the INERTIA of the sphere, the second term introduces DAMPING from FRICTION, and $\beta' = \sqrt{(\sigma_\omega/2\nu_{\text{kin}})}$ represents the reciprocal viscous influence, a scaling factor. Next the torsional oscillating sphere around its vertical axis surrounded by viscous liquid is discussed. Under these conditions, the outside medium is assumed to have an infinite radius. Due to the infinity condition, the solution reduces to functions of the first class ($n=1$) only. The torque on the oscillating sphere due to the outside viscous medium is now, in complex notation (accounting for damping), $\tau_F = -(8/3)\pi\eta_{\text{kin}}R^3 [(3+3ibR-b^2R^2)/(1+ibR)]\omega$. This torque reduces for long period to $\tau_F = -8\pi\eta_{\text{kin}}R^3\omega$, the negative sign indicates the counteracting influences of the viscous friction. A special case for this would be the harmonic rotation of a sphere within a sphere (*also see FORCED VORTEX*) (see Figure T.70).

Figure T.70 Torsional oscillation for a top-load washing machine.

Total angular momentum

[atomic, nuclear] The general mechanics definition of angular momentum is $\vec{L} = \vec{r} \times \vec{p} = \vec{I} \times \vec{\omega}$, $\vec{p} = m\vec{v}$, where I is the MOMENT OF INERTIA for the device and its orientation, r the radius, and v is the velocity of the object with mass m moving at a DISTANCE r . On a quantum-mechanical scale, the orbital angular momentum can be coupled to the SPIN angular momentum for the same electron, providing the respective total angular momentum. Similarly, the angular momentum of the NUCLEUS also provides its own influences. The total angular momentum on the quantum-mechanical level is defined by the orbital quantum number (ℓ) and spin quantum number ($s = \pm 1/2$) with QUANTUM NUMBER $j = \ell \pm (1/2)$, yielding $J = \sqrt{j(j+1)}\hbar$, where $\hbar = h/2\pi$, $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ is the PLANCK'S CONSTANT; with $(2j+1)$ z -projections $J_z = m_j\hbar$.

Total internal reflection

[general, optics] Under SNELL'S LAW of refraction $n_1 \sin \theta_1 = n_2 \sin \theta_2$ (the subscript $\square$ identifying the specific medium, n the index of refraction, and θ is the ANGLE with the normal to the surface at the interface), the ratio of index of refraction for the two media at a boundary can become smaller than 1 when the originating medium is more dense than the bordering medium. At a certain angle of incidence, the refraction angle becomes $90^\circ = \pi/2$, at which point the LIGHT will continue parallel to the interface after incidence. At greater angles of incidence, the electromagnetic RADIATION will be reflected, obeying the LAW OF REFLECTION: $\theta_r = \theta_i$. This phenomenon can render items "invisible" under water due to the viewing position of the observer with respect to the object at a great linear DISTANCE.

Total loss

[fluid dynamics] For a flow in a pipeline, the factors contributing to losses in ENERGY are the following: entrance loss; frictional loss due to shear at the WALL, frictional losses in elbows, valve orifices, friction losses in discharge branch off line (bi-, trifurcations, etc.), exit loss due to EXPANSION, next to the elevation of the flow (z). The respective head-loss factors add up as $h_{L,T} = K_i(v_s^2/2g) + [f_s(L/D)(v_s^2/2g) + f_d(L/D)(v_d^2/2g)] + \{K_b(v_s^2/2g) + [f_{dT}(L_e/D)_{\text{elbow}}(v_d^2/2g)]_{90^\circ}\} + f_{dT}(L_e/D)_{\text{valve}}(v_d^2/2g) + \text{branch-off} + K_e(v_d^2/2g) + (z_2 - z_1)$, where the average velocity can be derived from the flow rate (Q) as $v_s = \dot{Q}/A_s$ (A_s the total suction line exit cross-sectional area), $v_d = \dot{Q}/A_d$ (A_d the total discharge line exit cross-sectional area), f_s and f_d the FRICTION factor for suction and discharge respectively, D the tube diameter (assuming a constant diameter for the main section, the FLUID under consideration will provide the COEFFICIENT OF FRICTION (v_{kin}) and overall friction (η_{kin}). The REYNOLDS NUMBER for the flow yields information about the flow structure (turbulent or laminar), $Re = v_s D \rho / \eta_{\text{kin}}$, for both the main line and the respective discharge line(s). One important consideration is the RELATIVE ROUGHNESS of the wall $\chi_r = D/\epsilon_s$, where ϵ_s is the average "height" of the raised and carved general unevenness in the surface. The relative SURFACE ROUGHNESS (listed in reference tables, material property) in combination with the Reynolds number will provide the respective friction factors from Moody's diagram. The entrance coefficient K_i is a function of the shape, $K_i = 0.5$ for square edges; $K_i = 1$ for round outflow, similarly for the branches K_b and exit flow K_e . The values $(L_e/D)_{\text{valve}}$ for a valve, $(L_e/D)_{\text{elbow}}$ for an elbow can be found in design tables. The power supplied to enforce the flow in this case is $P_f = h_{L,T} \rho_f \dot{Q}$, where ρ_f is the fluid density. Incorporating

the pump efficiency γ_f will provide the operational requirements for the PUMP (in kwatt or horse power), where the electric pump quickly reach 75% efficiency (see Figure T.71).

Figure T.71 Total loss for a pipe flow system.

Total lung capacity (TLC)

[biomedical, fluid dynamics] The total volume of GAS filling the lungs at completion of a maximum inspiration. Total lung capacity and other TIDAL BREATHING parameters can be measured with a spirometer. (see RESPIRATION) (see Figure T.72).

Figure T.72 Diagram illustrating total lung capacity.

Total potential

[thermodynamics] The total potential of a system $\mu = \mu_0 + RT \ln(\rho RT / M p_0) - (1/2)\epsilon^2 [\alpha + (d^2/3kT)]$, where ϵ is the MAGNITUDE of a uniform ELECTROSTATIC FIELD (for instance in a CAPACITOR $\epsilon = \epsilon Q / A$ [ϵ is the DIELECTRIC permittivity, Q the total charge on the capacitor plates, and A is the area of the capacitor]), k is the Boltzmann constant, d the ELECTRIC DIPOLE MOMENT of the respective molecules in the volume, ρ the density, M the MOLECULAR WEIGHT, α the molecular POLARIZATION, and p_0 , μ_0 are constants, with $R = 8.314462175 \text{ J/Kmol}$ the universal gas constant. Similarly the total potential for the individual contributions by the electrons (sub_e), ions (sub_i), and atoms (sub_a) are given by the following respective expressions: $\mu_e = kT \ln[b^3 \rho_e(x) / g_e (2\pi m_e kT)^{3/2}] + \epsilon_0 \epsilon - q_e \psi(x)$; $\mu_i = kT \ln[b^3 \rho_i(x) / g_i (2\pi m_i kT)^{3/2}] + \epsilon_0 \epsilon - q_i \psi(x)$; and $\mu_a = kT \ln[b^3 \rho_a(x) / g_a (2\pi m_a kT)^{3/2}] + \epsilon_0 \epsilon$, where $\psi(x)$ is the electrostatic potential at position x .

Townes, Charles Hard (1915–)

[optics, solid-state] Physicist from the United States. Charles Townes worked on quantum ELECTRONICS principles and microwave ENERGY configuration, with a particular focus on radar applications. In 1964, Charles Townes received the Nobel Prize in Physics for his work on the MASER (microwave amplification by stimulated emission of radiation) with respect to the work published in 1954, the prelude to his participation in the development of the LASER. He shared the Nobel Prize with Nicolay G. Basov (1922–2001) and Aleksandr M. Prokhorov (1916–2002) (see [Figure T.73](#)).

Figure T.73 Charles Hard Townes (1915–).

Townsend, John Sealy Edward, Sir (1868–1957)

[atomic, nuclear] Mathematical physicist from Ireland. Townsend was a contemporary of ERNEST RUTHERFORD (1871–1937) at Cambridge University. In 1897, John Townsend conceived a method to measure the electrical charge, specifically the charge quota contained on an OIL drop in various amounts, hence deriving the QUANTUM effect and determining the single electron charge. This mechanism was later

perfected by ROBERT ANDREWS MILLIKAN (1868–1953). Additional work was in the WAVE theory for electrons and the general QUANTUM THEORY (see Figure T.74).

Figure T.74 Sir John Sealy Edward Townsend (1868–1957). (Courtesy of Biographical Memoirs of Fellows of the Royal Society 1957; JSTOR.)

Trace

[computational] In matrix theory, the sum of the ELEMENTS on the diagonal of an $n \times n$ matrix:

$$\begin{bmatrix} m_{11} & \cdots & m_{1n} \\ \vdots & m_{ii} & \vdots \\ m_{n1} & \cdots & m_{nn} \end{bmatrix}.$$

Tracers

[atomic, biomedical, fluid dynamics, geophysics, meteorology, nuclear] Chemically reactive agents and radioactive isotopes used for identification of metabolic and physiologic processes in specific anatomical locations. Additionally, tracers are used in FLUID DYNAMICS for flow pattern recognition; dyes. The iodine ISOTOPE is used in diagnostic modalities of the thyroid gland, based on gamma RADIATION emission from the iodine, by means of a gamma CAMERA. In the diagnosis of metabolic processes, the use of ¹⁸fluorine in POSITRON EMISSION TOMOGRAPHY (PET) provides insights into the GLUCOSE uptake and cellular consumption as integrated in 2-deoxy-2-(18F)fluoro-D-glucose. Other tracers used in PET imaging are ¹¹carbon, ¹³nitrogen, and ¹⁵oxygen. Histochemical tracers are used for analysis of chemical communications in the synopsis of neural connections. This type of tracer often consists of enzymes and is brought out by staining a biopsy sample. TRACER is an acronym for transition radiation array for cosmic energetic radiation, which is used in atmospheric analysis to gauge cosmic ray MAGNITUDE by means of sensor arrays attached to balloons.

Transcytosis

[biomedical, mechanics] Process under the active process of cellular ingestion of ENDOCYTOSIS, in this case the assimilation of large molecules such as ALBUMIN by means of the invagination process of the CELL MEMBRANE. The forming enclosure produces a vesicle that transports the package to the intercellular content where the vesicle detaches from the cell-membrane lining and subsequently the vesicle disintegrates to release the content for cellular integration.

Transducer

[acoustics, electronics, general, mechanics] Device with a specific transfer function, converting the **MAGNITUDE** of one phenomenon into another. The transfer function consists of a predetermined mathematical relationship that will prescribe a **PROBABILITY** distribution of the output. The translation of the magnitude of one physical quantity into another generally has a predictable response in order to preserve the integrity of the imbedded information. Transducers can function linearly or obey a square law response, or logarithmic/exponential behavior, generally smooth without discontinuities in the range of operations of interest. Transducers are used to convey information on electrical signal strength, temperature, acoustics, optics, as well as **MAGNETIC** and electric field strength next to a range of particles for **RADIOACTIVE DECAY** and elementary **PARTICLE** detection. The majority of devices have an electrical **SIGNAL** as output or for instance for acoustic probes as both input and output (piezoelectric). The most widely used is the **SOUND** transducer as a **MICROPHONE** and a “**SPEAKER**.” Inductive transducers are used as pick-up **ELEMENTS** for electric guitars. Photocells measure **LIGHT** radiance as well as respond to the remote control actuator.

Transformer

[electromagnetism, electronics, general] Electric device operating on the basis of the Faraday induction law. The transformer consists of two parts. An electrical potential applied to the primary winding produces a current that results in a **MAGNETIC FIELD** that is proportional to the number of windings. The magnetic field is captured in a **METAL CORE** that conveys it to a secondary coil. In the secondary coil, the magnetic field induces a current with associated electrical potential, where the electrical potential **MAGNITUDE** (V) is proportional to the number of windings (N). The conversion of the input to the output voltage ratio is directly proportional to the ratio of windings in the primary versus the secondary coil ($V_1/V_2 = (N_1/N_2)$) (see [Figure T.75](#)).

Figure T.75 Diagram outlining the mechanism of action for the transformer.

Transient equilibrium

[nuclear] Equilibrium that is reached through a mediator stage. In nuclear science, the transient state is accomplished through a parent daughter transition where the half-life of **DECAY** for the daughter is shorter than the parent but not intrinsically negligible. The transient equilibrium in **RADIOACTIVE DECAY** is represented by the Bateman equation, linking the parent decay half-life time (τ_p) to the daughter decay half-life time (τ_d) by the definition of the **ACTIVITY** of parent ($A_p = \lambda_p N_p$; $dN_p/dt = -\lambda_p N_p$, λ_p the decay constant of the parent) and offspring ($A_d = \lambda_d N_d$; $dN_d/dt = -\lambda_d N_d$) respectively, captured as $A_d/A_p = \tau_p/(\tau_p - \tau_d)$ BR, where BR is the branching ratio (ratio of decaying particles under a specific process of decay to the total number of decaying particles). The Bateman equation defines the activity

of the daughter as $\mathcal{A}_d = \text{BR} \{ \mathcal{A}_p(0) [\lambda_d / (\lambda_d - \lambda_p)] [e^{-\lambda_p t} - e^{-\lambda_d t}] \} + \mathcal{A}_d(0) e^{-\lambda_d t}$. The time of maximum activity ($t_{\max}$) for the daughter activity in transient equilibrium has an inherent maximum defined as $t_{\max} = 1.44 [\tau_d \tau_p / (\tau_p - \tau_d)] \ln(\tau_p / \tau_d)$, which may exceed the parent activity under certain conditions, in which case there will be *no* EQUILIBRIUM STATE.

Transistor

[atomic, electronics, general, nuclear] Electronic device made from semiconductor materials, or a VACUUM tube that can provide a special electronic function. By means of connecting resistors, capacitors, or inductors to the poles of a transistor, the function can be designed to provide SIGNAL amplification, integration, or differentiation. The specific integration of the transistor in circuits can provide an operational amplifier (also known as INTEGRATED CIRCUITS: IC). The general transistor design consists of two. The semiconductor construction can be npn or pnp. The “n” represents a semiconductor with a donor impurity, doped with electrons, providing a rise in the FERMÍ LEVEL for the ENERGY structure. A P-TYPE SEMICONDUCTOR has an ACCEPTOR IMPURITY that creates a “shortage” of electron, rather represents “holes” with an inherent lowering of the Fermi level. Joining the *p*- and *n*-type media provides a preferred electron migration as is seems for the DIODE. In the transistor, there are three regions of impurities, two of similar nature separated by the complementary energy structure. The material that is sandwiched between the two identical media can have its energy structure manipulated under the influence of an external electrical potential, referred to as the base. The other constituents are the emitter and the collector. The applied electrical potential on the base of the transistor can raise or lower the Fermi level that will accommodate the transport of electrons between the emitter and the collector. Note that the collector “accepts” current, which relates to the emission of electrons; current running from the external power supply’s positive to negative terminal through any electronic device. The construction of the semiconductor layers generally allows for only very thin segment reserved for the “base,” which provides a limited constraint for the electron migration between the emitter and collector only. The base thickness is directly affected by the DRIFT VELOCITY for the electrons; hence, a small thickness yields minimal RESISTANCE. The moment the electrons penetrate the collector volume they have passed the junction that holds a POTENTIAL BARRIER; thus, back DIFFUSION is deemed impossible. Transistors form an essential component in electronic design, using the RESISTOR, CAPACITOR, and INDUCTOR as a means to perform a specific task. Recently a new class of transistors has been introduced: organic luminescent transistors (see PNP-TRANSISTOR, NPN-TRANSISTOR, OPERATIONAL AMPLIFIER, PN-JUNCTION, and DIODE) (see Figure T.76).

Figure T.76 Classic transistor design, before surface mount miniaturization.

Transmission electron microscope

[biomedical, imaging, nuclear, solid-state] **ELECTRON MICROSCOPE** that measures the transmitted intensity of electrons as a function of location to form an **IMAGE**. The electron microscope was a major implication of the discovery of the electron by **JOSEPH JOHN THOMSON** (1856–1940) in 1897. **HEINRICH HERTZ** (1857–1894) was one of the first who realized that **CATHODE RAYS** were a form of **WAVE MOTION**. Electrons are still generated as a result of a thermoelectric event: thermionic electron gun. In 1899, both the French physicist Alfred-Marie Liénard (1869–1958) and the German scientist Emil Johann Wiechert (1861–1928) independently performed the first mechanism of action to concentrate the cathode rays by means of an axial **MAGNETIC FIELD** produced by a long **SOLENOID**. Hans Busch (1884–1973) provided the theoretical evidence of electron focusing in 1926 (German pioneer in electron optics). In 1931, two German engineers Ernst Ruska (1906–1988) and Maximillion Knoll (1897–1969) performed the first magnification of an electron image. In 1933, Ernst Ruska built the first prototype electron microscope, which was perfected in 1938 by Eli Franklin Burton (1879–1948) in collaboration with his graduate students Cecil Edwin Hall (1912–1991), James Hillier (1915–2007), and Albert Prebus (1931–2000). The transmission microscope, as the word indicates, uses an electron beam, operating at the **DE BROGLIE WAVELENGTH** (**LOUIS VICTOR PIERRE RAYMOND DUC DE BROGLIE** (1892–1987), French physicist postulated the **WAVE** theory of matter in 1924), with the collection of electrons as a function of location on the opposite side of a sample. An electron beam is steered through the manipulation of magnetic fields (**STEM**: scanning transmission electron microscopy). Since the interrogation is performed by means of ballistic electrons, the in-path attenuation must be kept to a minimum; hence, the imaging needs to be performed under mid to high **VACUUM** conditions ($< 10^{-3}$ torr = 0.133 pa). The probing beam is on average 0.5–1 μm in diameter. The resolution (D_r) for the wavelength (λ) associated with the electron trajectory can be defined including an aberration correction with respect to spherical distortions due to the objective's magnetic field (C_s) as $D_r = AC_s^{1/4}\lambda^{3/4}$, where $0.43 < A < 0.7$ is a device and sample material preparation constant. The **RESOLUTION** ranges from 0.5 nm for an acceleration potential of 20 kV to 0.12 nm for an acceleration potential of 1000 kV ($\lambda = 0.004$ nm) (see **ELECTRON MICROSCOPE**) (see [Figure T.77](#)).

Figure T.77 Transmission electron microscope and operational design and transmission electron imaging representation of neutrophil cells.

Transport equation

[astrophysics/astronomy, fluid dynamics, general, mechanics, optics] Theoretical approach to describe the ordered **MOTION** of particles and photons. The forced migration of particles covers a broad range of phenomena, including but not limited to, the **LIGHT** propagation in tissue under laser irradiation, the **NEUTRON** transport in a **NUCLEAR REACTOR**, the “**DIFFUSION**” of gas and solutes, and the electromagnetic and particle emission for galactic entities (primarily stars). In all cases, the migration process is hindered by

the interaction with substances in the trajectory such as, molecules, ions, dust, uranium-238, and control rods (boron or hafnium or cadmium). The transport equation is a mix of integration and differential operators, accounting for diversion, attenuation, and gain next to source conditions, all as a function of location. Each PARTICLE for a system consisting of a fixed or known number of components (N) has an associated $6N$ first-order differential equations describing the interaction, not accounting for the internal DEGREES OF FREEDOM of the ELEMENTS. The approximation is made that there is consistency for all particles, assuming a PROBABILITY distribution for the spread in parameters associated with the system as a whole. In this case, the transport equation is defined for a single particle. The Transport equation can be considered either as a steady-state problem or as a time-dependent process. The steady-state condition will reduce the complexity on various levels. The introduction of the equation of transfer/transport equation was made by LUDWIG EDUARD BOLTZMANN (1844–1906) in 1872, although he received inspiration/assistance from JAMES CLERK MAXWELL (1831–1879). The formulation adheres to the migration process of a “dilute” GAS MIXTURE with the distribution function $P^{\text{prob}}_i(\vec{r}, \vec{v}_i, t)$ for constituent i at location r in the direction dr , each traveling with velocity v_i at a time t . The interaction probability is indicated by a CROSS SECTION σ_{ij} , with the redirection of the vector captured by $g_{ij}(\theta_i)$, with θ_{ij} the per incidence scattering ANGLE, which is the so-called scattering anisotropy factor or scattering function (also referred to as g-factor). All “particles” are considered to engage a finite volume in space where the items converge from with a solid angle $d\Omega'$ and those will leave the volume after interaction within a solid angle $d\Omega$. The “source” or origin of the particles (photons) is defined through the introduction of a source function $\xi(\vec{r}, \vec{v}_i, t)$. The source can be designed a certain way or follows directly from material properties. A laser beam will be concise and has a Gaussian profile as a function of location (single wavelength; single propagation velocity), whereas a NEUTRON source will be covering full 4π solid angle (for simplicity, one can assume a fixed ENERGY and hence single velocity; and uniform emission angle). The time-dependent formulation is as follows: $(\partial P^{\text{prob}}_i / \partial t) + \vec{v}_i (\partial P^{\text{prob}}_i / \partial \vec{r}) + \xi(\vec{r}, \vec{v}_i, t) (\partial P^{\text{prob}}_i / \partial \vec{v}_i) = \sum_{j=1}^n \iiint \{ P^{\text{prob}}_i P^{\text{prob}'}_j - P^{\text{prob}}_i P^{\text{prob}}_j \} g_{ij}(\theta) \sigma_{ij} d\Omega dv'$, integrated over all space under solid angle Ω . Generally this type of integro differential equation needs to be approximated under certain constrains, or the equation is solved numerically. One approximation is the reduction to a two- or three-flux model, or limit the SCATTERING interaction: only consider isotropic scattering; additionally confining the speed to a single velocity provides a more solvable problem. The transport equation can under limiting constraints be developed in a series that can be truncated under specific boundary conditions. One particular SOLUTION technique using computer simulation is referred to as the MONTE CARLO METHOD, referencing the chance interaction. The Monte Carlo method required defining an appropriate look-up table for the random processes captured by P^{prob}_i , while proposing a single value process for σ_{ij} , and $g_{ij}(\theta_i)$. A special case of the transport equation applies to the fluid-dynamics process of turbulent flow for particles mixtures. For the VELOCITY POTENTIAL of the SOLUTE particles the vorticity is defined as $\vec{\omega} = \nabla \times \vec{v}$. The vorticity transport equation is defined as $D\vec{\omega}/Dt = (\vec{\omega} \cdot \nabla) \vec{v} + \eta_{\text{kin}} \nabla^2 \vec{\omega}$, where $D\vec{\omega}/Dt = \partial \vec{\omega} / \partial t + (\vec{v} \cdot \nabla) \vec{\omega}$, $(\vec{\omega} \cdot \nabla) \vec{v}$ is the “vortex stretching;” the change in particle rotation rate due to velocity gradients, $\vec{v}$ the velocity, $\eta_{\text{kin}} \nabla^2 \vec{\omega}$ describes the diffusion under viscous flow, with η_{kin} the KINEMATIC VISCOSITY that is equal to the diffusion coefficient for diffusion of vorticity. Note that vorticity describes the degree of “rotation” experienced in flow VELOCITY ($\vec{v}$) as a function of location ($\vec{r}$) and TIME (t) expressed as $\vec{\omega}(\vec{r}, t) = \nabla \times \vec{v}(\vec{r}, t)$ (also see EQUATION OF RADIATIVE TRANSFER and TORSIONAL OSCILLATIONS).

Transuranic element

[atomic, nuclear] ELEMENT with atomic number greater than 92 ($Z > 92$; heavy) as listed in the PERIODIC TABLE OF ELEMENTS. Note that $Z = 92$ represents uranium. All elements at $Z > 92$ are radioactive and short lived with lifetime smaller than the AGE of the UNIVERSE as we know it. All currently available transuranic elements have been formed artificially; however, an ISOTOPE of the element plutonium ($Z = 94$) with a half-life of 80 million years has been identified in nature. The lighter transuranic elements ($89 < Z < 103$, full set of 15) is classified as actinides with similar chemical properties to the actinides $57 < Z < 71$. Elements with atomic numbers greater than 100 can only be formed by colliding heavy ions with the atomic number greater than that of helium, forming small quantities, at best several hundred atoms. Based on the formation of the very large nuclei, it has been indicated that $Z = 109$ may be limit of “stable nuclei.”

Although there is a hypothesis that predicts an “island” of nuclear stability in the region $114 < Z < 126$, this remains still to be verified.

Transverse electromagnetic (TEM) waves

[general] Electromagnetic waves in VACUUM are formed by an electric and a MAGNETIC FIELD that are perpendicular to each other as well as to the direction of propagation, which forms the standard definition of electromagnetic RADIATION. However, in CONDUCTOR and semiconductor materials, this may not always hold absolutely true.

Transverse waves

[general] WAVE with the displacement perpendicular to the direction of propagation, for instance a wave on a string or a WATER WAVE; in contrast to a LONGITUDINAL WAVE (compression wave, e.g., SOUND). For a transverse wave, the speed of propagation is a function of the inertial properties of the object in MOTION, the elastic properties of the medium providing the conduction but not the motion of the source. The velocity of propagation (v_w) for a transverse wave on a string is a function of the tension of the string (F_T), and the MASS (m) per unit length (L) with respect to the string itself: $v_w = \sqrt{F_T/(m/L)}$. By changing the tension, the resonant frequency (v_{res}) for the string is altered due to the wavelength (λ) dependency on the tension and the length of the string (ℓ) through $v_{\text{res}} = n(v_w/2\ell)$, $n = 1, 2, 3, \dots$ with the FUNDAMENTAL FREQUENCY for $n = 1$. This involves the tuning of any string instrument. The longest wavelength for a string fixed on both extremes will be one half the wavelength (*also see* COMPRESSION WAVE, ACOUSTICS, and SOUND) (see Figure T.78).

Figure T.78 Transverse wave concept illustrated string plucked generated displacement perpendicular to the direction of motion of propagation, which is along the length of the string.

Traveling salesman problem

[computational] Minimized RANDOM WALK outline. The traveling salesman is trying to configure a route that will allow him to visit each city on his sales list with the shortest time while visiting each city only once and returning to his home. The concept represents determining the optimized process and was introduced in the early 1930s.

Tremor

[acoustics, biomedical, geophysics, mechanics] Structural vibrations, as found in EARTH'S CRUST and buildings and smaller devices. Tremors also describe small EYE movement in the classification of fixation on a point. Other classifications are MICROSACCADE and DRIFT.

Triboelectric sequence

[general] “Tribo” is a Greek word that stands for “FRICTION,” thus referring to the charge transfer between two surfaces as a result of physical contact under MOTION. The triboelectric process provides

the means to transfer charge and generate static ELECTRICITY potential ENERGY resulting from friction. Walking on a polyester carpet is the prime example, specifically under low HUMIDITY. One specific triboelectric phenomenon is the charge separation when clear plastic tape is quickly unwound, maybe using a mechanical rotary axle such as a drill. The charge separation will form arcs that are visible in blue and invisible ULTRAVIOLET. The speed of separation is critical based on the surface conduction leaching off the charge and discharge by means of conduction through the AIR by the lingering humidity. Similar effects may also be observed when spooling a recording tape on older tape-recorder MACHINES (see [Figure T.79](#)).

Figure T.79 Example of the conditions that may lead to triboelectric activity balloon has been rubbed and accumulates static charge.

Triple point

[general, thermodynamics] In a pressure versus temperature PHASE DIAGRAM of a substance there is a point where LIQUID, solid, and gas exist simultaneously. Raising or lowering the temperature or pressure will lead to phase transitions: EVAPORATION, SUBLIMATION and liquification (as well as all the reverse processes). For instance, for water at this point will have the coexistence of liquid water, solid ice, and water vapour (see [Figure T.80](#)).

Figure T.80 Triple point, carbon dioxide compared to water.

Triplet, Wild's

[astrophysics/astronomy, geophysics, mechanics, optics] (syn.: galaxy) {use: energy, imaging, origin-of-life (Big Bang)} Wild's triplet GRAVITATION bridge between three galaxies, forming an optimal spatial ANGLE between the respective galaxies (see **WILD'S TRIPLET**).

Triplet state

[atomic, computational, condensed matter, energy, kinetics, nuclear, solid-state] Two coinciding SPIN states for two particles (electron and PROTON) within an atomic structure that result in a spectral HYPERFINE STRUCTURE splitting (spin $S = 1$, quantity $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK'S CONSTANT), for example, H_2 PROBLEM. This stands in contrast to a SINGLET STATE (spin $S = 0$). In case two electrons converge on a zero angular momentum than the three states are ENERGY degenerate in the values m_s . Singlet oxygen, $\text{O}_2(a^1\Delta_g)$, is the lowest excited electronic state that has been known for molecular oxygen, and has been recognized for at least 80 years. The characteristic chemistry of excited singlet oxygen sets it apart from the triplet GROUND STATE of molecular oxygen, $\text{O}_2(X^3\Sigma^-_g)$. The triplet state can potentially degenerate by PHOSPHORESCENCE. The DEGENERACY for the triplet state can however be removed when an external MAGNETIC FIELD is applied, as described by the ZEEMAN EFFECT (see [Figure T.81](#)).

Figure T.81 Triplet state.

Triple-twin domain

[nanotechnology, quantum] {use: elementary particle} Gathering of misplaced ATOM clusters giving rise to local changes in the CRYSTAL STRUCTURE equivalent to the insertion of three nonrelaxed atomic cells. This phenomenon can be described by NUCLEAR FORCES (i.e., the sharing of elementary PARTICLE such as mesons) and van der Waals forces. The van der Waals interaction was discovered by the Dutch scientist JOHANNES DIDERIK VAN DER WAALS (1837–1923). They are the attractive or repulsive forces between molecules and ELEMENTARY PARTICLES that are not the larger scale covalent bonds or due to the ionic electrostatic interaction. The VAN DER WAALS FORCE (also: London–van der Waals) is described by an EQUATION OF STATE of a diluted IDEAL GAS (expressed by the GAS LAW: $P = (N/V)[1 - (aN/VkT)]kT$, where N is Avogadro's number, V and P are the volume and pressure respectively of the "gas," k is the Boltzmann's constant, T the temperature of the "gas," and a the dilution factor) and is related to the Casimir effect for DIELECTRIC media. The phenomenological description assumes interactions between nonzero size particles (i.e., atoms) as a FLUID with a pairwise attraction diminishing roughly according to $1/r^6$, r being the DISTANCE between the pair. Johannes Diderik van der Waals received the

Nobel Prize in Physics in 1910 for his work on the “Equation of state for gases and liquids” published in 1873. The modified IDEAL GAS LAW approximating fluids describing the van der Waals force is given as $F_{\text{vanderWaals}} = (d_1/r^s) - (d_2/r^t)$, where $s \approx 6$ and the second term represents a repulsion with $t \approx 2$ and d_1 and d_2 are size representing constants.

Trochoidal waves

[fluid dynamics] WAVE pattern defined as the curve traced out by a point on a circle as the circle is rolled along a line. The wavelength (λ) of the rolling circle with radius R now becomes $\lambda = 2\pi R$. The wave shape in longitudinal and transverse directions is respectively given as $x = (\lambda/2\pi)\theta - (\lambda/40)\sin\theta$ and $z = (\lambda/40)(1 - \cos\theta)$, where θ represents the ANGLE of rotation of the circle defining the MOTION of the “water molecules.” One notable wave pattern approximation was introduced by William Newell Bascom (1916–2000). In this model, the peak of the wave becomes sharper with increasing AMPLITUDE of higher harmonics. In the Bascom model, the maximum wavelength to wave peak ratio is 7:1, while a peak is not considered a peak if the full angle of the high water level is less than 120° (see [Figure T.82](#)).

Figure T.82 Trochoidal wave patterns.

Troposphere

[energy, geophysics, thermodynamics] The portion of the Earth’s ATMOSPHERE that we live in, reaching out to approximately 17 km altitude. The troposphere generally consists of the following elementary gasses: nitrogen (on average ~78.09%), oxygen (~20.95%), argon (~0.93%), and carbon dioxide (0.039%) and trace-elements, all as a function of location. Additionally, it holds better than 80% of the earth’s water VAPOR, accounting for various forms of cloud formation, precipitation, and ABSOLUTE HUMIDITY. Pioneers in the study of the earth’s

atmosphere and troposphere are the French scientist and meteorologist Léon Teisserenc de Bort (1855–1933) and the German meteorologist Richard Aßmann (ASSMANN; 1845–1918) (see [Figure T.83](#)).

Figure T.83 Troposphere.

Trouton, Frederick Thomas (1863–1922)

[atomic, optics, thermodynamics] Physicist from Ireland. Frederick Trouton performed experimental verification of the earth's AETHER concept; the luminiferous aether (ETHER), the assumed medium required to propagate electromagnetic RADIATION. It was later discovered that the luminiferous aether does not exist; electromagnetic radiation is ENERGY transported through VACUUM as well as AIR and most solids. Trouton's work on THERMODYNAMICS revealed the correlation between the MOLECULAR WEIGHT of substances and the heat of vaporization, known as Trouton's law. Additional work in OPTICS by Frederick Trouton indicated the POLARIZATION interaction on a molecular level, associating the molecular VIBRATION of a substance with the direction of polarization for transmitted LIGHT, also used by EDWIN HERBERT LAND (1909–1991) in 1928, for the polaroid film design (see [Figure T.84](#)).

Figure T.84 Frederick Thomas Trouton (1863–1922). (Courtesy of Proceedings of the Royal Society (London), A110, 4, 1926.)

Trouton's rule

[atomic] The entropy of vaporization (ΔS_{vap}) at the boiling point is virtually identical for most LIQUID substances: $\Delta S_{\text{vap}} = 10.5R$, where $R = 8.3144621(75) \text{ J/Kmol}$ is the GAS constant. This rule was expressed in 1884 by FREDERICK TROUTON (1863–1922). With modifications including TEMPERATURE (T) dependence, the validity was extended and is defined as $\Delta S_{\text{vap}} = 4.5R + R \ln T$.

Tsunami

[fluid dynamics, general, geophysics, mechanics] Significant water mass displacement in a WAVE pattern resulting from a sudden perturbation, such as an underwater EARTHQUAKE, volcanic eruption, or landslide, next to for instance a METEOR impact. Tsunamis may be created artificially by explosions as well. In deep water, the tsunami may be composed of a wave pattern over a large surface area with AMPLITUDE of only several CENTIMETERS, but may be as high as several meters. When the wave pattern approached the shallow waters on the shoreline, the wave amplitude may increase dramatically with significant destructive effects due to the sheer MAGNITUDE of the volume of water and the associated force. Due to the deep water at the origin and the large quantity involved, the velocity of the tsunami WATER WAVE can reach excessively high numbers, the wave will slow down as the water depth decreases, potentially in deep water in excess of 200 m/s (see [Figure T.85](#)).

Figure T.85 Tsunami (exaggerated).

Tsvet, Mikhail Semyonovich {Михайл Семёнович Цвет} (1872–1919)

[biomedical, optics] Russian scientist and botanist. Inventor of the concept of CHROMATOGRAPHY, using spectral analysis for identification of biological entities based on molecular optical attenuation information (see Figure T.86).

Figure T.86 Mikhail Semyonovich Tsvet (1872–1919).

Tuft flow

[fluid dynamics] The use of “streamers” to visualize flow patterns. Streamers or tufts are finite length strips attached to a surface of specific contour, placed at regular intervals. Flow can be represented in several different ways in a two-dimensional manner: arrow plots (sometimes referred to as hedgehogs), ribbons, streamlines, line-integral convolution, or streaklines. Arrow plots are an instantaneous representation of the vectors of flow velocity as a function of location. In experimental setting, the use of streamers is used to TRACE the flow. The streamers can be solid material strips or can also be smoke emerging from small orifices spread out over the surface of interest, as well as ink jets. The use of mechanical tufts can indicate streamlines, outlining where the flow field is tangent. Used in the automobile industry for aerodynamic assessment. Also seemingly random WAVE pattern in the grassy leaves on the soil. The grass bends in directions that are compatible with the pressure patterns associated with a turbulent and inhomogeneous wind pattern. The leaning ANGLE and direction of the grass leaves are visual indications of flow stream and to a degree of vorticity. The tuft used for artificial experimental indication of direction and MAGNITUDE resembles the grass leaf, tapering out to the point of attachment. Due to the mechanical structure of the tuft, the full extension of lean provides an indication of magnitude, since the thicker portions at a lower height require a greater force to bend. The physical representation of the bending tuft considers the tuft as a damped bending/flexing strip of variable thickness that obeys Hook’s law: $F_{\text{spring}} = \kappa_i (\ell_{\text{distended}} - \ell_{\text{rest}})$, with κ_i the spring constant and ℓ_i the length. The DAMPING force of the bending spring is proportional to the velocity of movement (proportional to the flow velocity) (ν) and the damping constant (κ_d) expressed as $F_{\text{damping}} = \kappa_d \nu(t)$. The flow will apply an external force (F_{flow}) that provides the sum of forces: $F_{\text{total}} = F_{\text{flow}} + F_{\text{spring}} + F_{\text{damping}}$. Due to the variable “thickness” of the streamer, the streamer (e.g., grass leaf) can for convenience be subdivided in segments with different material properties, with a lower limit of 3 to minimize the complexity of the problem without losing critical information about the flow. Additional segments will add to the computational intricacy. The tip displacement is a direct indication of the flow

velocity (direction and magnitude) and the applied flow force, within certain limits (there will be a maximum force that will LAY the streamer flat on the surface). The SOLUTION process can use either the Euler method or RUNGE–KUTTA METHOD for the integration over the different segments (see Figure T.87).

Figure T.87 Tuft flow, plants blown over in various directions due to strong localized wind gusts in random directions for a rice field.

Tungsten filament

[general] “black-body” metal ELEMENT composed form the element tungsten, specifically used in the light-bulb design based on Thomas Alva Edison’s (1847–1931) invention in 1879 that emits LIGHT under the conduction of current (I), while resistive heating of the tungsten wire yields a temperature that provides a COLOR in the yellow/white visible light. The electrical RESISTANCE (R) results in a power conversion (electric to kinetic) of $P = I^2 R$. Resistance generally increases with TEMPERATURE (T) and is generally expressed by the resistivity (ρ_{res} ; $R = \rho_{\text{res}}(L/A)$ for a wire of length (L) and cross-sectional area (A) as $\rho_{\text{res}} = \rho_{\text{res},0}(1 + \alpha_0 \Delta T)$, with α_0 the temperature coefficient of resistivity; a material property (see Figure T.88).

Figure T.88 Tungsten filament.

Tunneling

[nuclear] Also known as TUNNELLING (see QUANTUM TUNNELLING and BARRIER PENETRATION).

Turbine

[energy, fluid dynamics, thermodynamics] Device that under the influence of mechanical MOTION (momentum, force), generally in the format of flow, generates work or specifically ELECTRICITY. The CONSERVATION OF ENERGY law applies and provides the conversion of potential ENERGY to kinetic energy, next to conversion of kinetic energy to work or electric energy (with a loss term as heat, resulting from FRICTION). The mechanism of action for the generation of electrical power relies on rotation combined with a MAGNETIC FIELD, which provides a changing magnetic FLUX captured by a wire loop. The wire-loop magnetic field combination provides an induction, based on the principles of the Faraday induction law. Either a PERMANENT MAGNET is rotating within a wire loop or a wire loop is rotating within a fixed magnetic field. The FLUID flow may be water as in a hydroelectric plant, steam (nuclear power plant, fossil fuel burning power plant), wind as applied to wind-mill generators, piston ENGINE driven axle, and free-running cart with rotating axle as the core of the GENERATOR (turbine). Additional mechanisms are available, such as WAVE MECHANICS where a hinge attached to two plates is changing the ANGLE of attachment under the influence of ocean SURFACE WAVES. The hinge will thus provide an alternating change in captured magnetic flux from the interaction between the “knuckles” of the casing and the axle. An alternative configuration may be by means of a worm-wheel gear system, providing continuous rotation in response to a back-and-forth motion. Wind mills provide several work functions dating back to millennia. The use of wind power to PUMP water out of the GROUND may be the oldest. Wind mills have also been used to pump water from low areas to higher areas to dry out the land for habitation as was done in the north-western part of the Netherlands (north of Amsterdam) in 1533, further institutionalized by the engineer and architect Jan Adriaanszoon Leeghwater (1575–1650) in 1607 (by the way, the last name “Leeghwater” translates as “empty water,” where the original last name was most likely “Adriaanszoon,” but he is known as *Leeghwater*) (see [Figure T.89](#)).

Figure T.89 Schematic of gas turbine.

Turbo machine

[fluid dynamics, mechanics] An assembly of blades, or scoops that require ENERGY to operate (e.g., PUMP) or generate energy (e.g., TURBINE) by means of facilitating flow of a LIQUID through a system of channels, or passages that are configured around an axis of rotation to form a rotor. The turbo mechanism of action either adds energy to the system resulting from an external source of power to operate the system or extracts energy from flow and generates another form of energy, potentially ELECTRICITY (see [Figure T.90](#)).

Figure T.90 Turbo charger.

Turboprop engine

[fluid dynamics, mechanics] Combustion TURBINE engine that engages a PROPELLER through a reduction gear. The exhaust gases of the turbine transmit the power from the turbine by means of a shaft to a reduction gear. The use of a down shift in gear is required due to the fact that optimum propeller performance performs at much slower speeds than the revolutions per minute of the turbine. Turboprop engines are a compromise between turbojet engines and mechanical propeller engines (see [Figure T.91](#)).

Figure T.91 Turboprop engine.

Turbulence

[computational, fluid dynamics, geophysics] Fluid flow with a diverse vector spread of flow velocity as a function of location in a three-dimensional space. Turbulent flow will contain vortices, specifically near boundaries that are changing direction with respect to the flow; or obstructions. The potential for developing turbulence is indicated by the **REYNOLDS NUMBER**, which defines the boundary conditions for an incompressible, inviscid viscous flow as a function of flow velocity and interaction range. Under a low Reynolds number, a flow is laminar ($Re < 2000$), while turbulence will be in effect for $Re > 3000$. Turbulence can result from colliding/passing airstreams, as experienced during airplane flight. An associated phenomenon is turbulent **MIXING**, taking place in the **SURFACE BOUNDARY LAYER** with respect to airflow in close proximity to the earth's surface in response to the amalgamated relief patterns as well as colliding airstreams (see [Figure T.92](#)).

Figure T.92 Turbulent flow.

Twin "paradox"

[general] A popular concept in special relativity is traveling at velocities close to the speed of **LIGHT**. In this case, when two people (twins) are separated based on their profession to perform certain tasks, where one of the twins will have to travel to a distant planetary system at 6 light-years away, while the other twin remains on **EARTH** performing the data communications with the other twin. The spaceship travels at $v = 0.9c$, $c = 2.99792458 \times 10^8 \text{ m/s}$ the speed of light. Upon the return the time lapse is $t = (2 \times 6 \text{ light-years}) / 0.9c = 13.3 \text{ years}$. The person remaining on the Earth will have aged 13.3 years, while the person in the spaceship has only aged $\Delta t = 13.3 \text{ years} \cdot \sqrt{1 - (0.9)^2} = 5.8 \text{ years}$. The paradoxical part of this process is that both persons are going to **AGE** at the same rate. The traveling person may return sooner than anticipated (note that at this point the **GENERAL THEORY OF RELATIVITY** has not been considered). The two people may consider themselves at the origin of their own reference frame, traveling with respect to each other. The **INERTIAL REFERENCE FRAME** of the astronaut changes from the same as the twin to the inertial reference frame of the outbound voyage, followed by the inbound voyage (not stopping at the remote location) and returning to the fourth and final inertial reference frame that is the same as the inertial reference frame of the person remaining behind on the Earth. The fact that accelerations are involved for the traveling astronaut, leaving Earth, changing direction on location, and slowing down to land will affect the personal process of time. During the two trips themselves, there is no relativistic interaction. Due to the aspect of acceleration, the general theory of relativity needs to be invoked as well. Integration of all aspects of relativistic **MOTION** results in

a physical changes/differences in AGE, making the traveler arrive back younger (*also see* TIME DILATION, SPECIAL THEORY OF RELATIVITY, *and* GENERAL THEORY OF RELATIVITY (see [Figure T.93](#)).

Figure T.93 Twin paradox.

Two-photon absorption

[general, imaging, optics, quantum] Absorption process where two photons are converging on the identical absorbing atomic structure at the exact same time, and, based on the superposition principle, the ENERGY content will have doubled upon interaction, hence providing the exact same effect as the interaction of a single photon with half the wavelength. In this manner, the deeper penetration of long WAVE photons can provide the advantage of deeper penetration and hence avoiding surface effects. The only manner in which the conditions of two-photon absorption can be created is by increasing the PROBABILITY through the release of a massive amount of photons. This large PHOTON quantity corresponds to a high fluence, which can only be achieved under extremely short-pulse duration. Two-photon absorption provides an essential and useful spectroscopic tool.

Two-slit diffraction

[optics] *See* DOUBLE SLIT.

Tyndall, John (1820–1893)

[general, geophysics] Physicist from Ireland. John Tyndall worked on THERMODYNAMICS aspect related to the optical properties of gasses and constructed the first known relative spectrophotometer, measuring the absorption as a function of wavelength in relation to neighboring wavelengths (qualitatively). Based on his observation, Tyndall concluded that the water VAPOR in the Earth's ATMOSPHERE acted as a "blanket" preventing radiative heat loss, thus keeping the surface warm. Tyndall also worked on MAGNETISM and diamagnetic polarity. John Tyndall concluded in 1865 that the emission from a platinum wire heated to 1473 K was approximately 11.7 times more powerful than at 798 K. These experiments were repeated in 1879 by the Austrian scientist JOSEF STEFAN (1835–1893) who derived a generalized statement of emission proportionality with respect to TEMPERATURE (T) to the order T^4 . This was later supported by

LUDWIG EDUARD BOLTZMANN (1844–1906) in 1884 to provide the STEFAN–BOLTZMANN LAW for BLACK-BODY EMISSION as a power function $P = \sigma_{\text{SB}}AT^4$, where $\sigma_{\text{SB}} = 5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4$ the Stefan–Boltzmann coefficient, and A the emissive area (see [Figure T.94](#)).

Figure T.94 John Tyndall (1820–1893). (Courtesy of Chandler B. Beach, *The New Student's Reference Work for Teachers Students and Families*, Chicago, IL: F. E. Compton and Company, 1909 the private collection of Roy Winkelman.)

Taylor & Francis

Taylor & Francis Group

<http://taylorandfrancis.com>

U-234 ($^{234}_{92}\text{U}$)

[atomic, general, nuclear] Uranium isotope, the least prevalent ISOTOPE of uranium (TRACE).

U-235 ($^{235}_{92}\text{U}$)

[atomic, general, nuclear] Uranium, the second most abundant ISOTOPE of uranium (~0.72%). When a uranium $^{235}_{92}\text{U}$ ATOM is bombarded by a NEUTRON (^1_0n), the FISSION results are as follows: three neutrons, a barium atom ($^{138}_{56}\text{Ba}$), and a krypton atom ($^{95}_{36}\text{Kr}$) (see [Figure U.1](#)).

Figure U.1 Decay process for an unstable uranium isotope.

U-238 ($^{238}_{92}\text{U}$)

[atomic, general, nuclear] Uranium, the most abundant ISOTOPE of uranium ($\sim 99.27\%$) (see URANIUM) (see [Figure U.2](#)).

Figure U.2 Illustration of the element uranium.

Uhlenbeck, George Eugene (1900–1988)

[atomic, nuclear] Physicist and chemist from the Netherlands who, in 1925, introduced the concept of ELECTRON SPIN simultaneously but independently from SAMUEL GOUDSMIT (1902–1978) while working under PAUL EHRENFEST (1880–1933), based on the description of the four QUANTUM numbers associated with the electron introduced by WOLFGANG PAULI (1900–1958) (see [Figure U.3](#)).

Figure U.3 George Eugene Uhlenbeck (1900–1988).

Ultimate stress

[biomedical, general, mechanics, solid-state] Parameter defining the strength of a material, at this applied stress the material will fail.

Ultimate tensile strength

[general, mechanics, solid-state] Generally strength of a material indicates the ability to resist applied force without failure. The point in the stress–strain curve where the stress starts to decline with increasing strain is the ultimate strength. At the point of the ultimate strength, the material will start to “neck-down” as seen under the stress applied by a device such as an instron, a standard for quality control (see [Figure U.4](#)).

(a)

(b)

Figure U.4 Ultimate tensile strength, fracture under externally applied tension. (a) Graphical representation of the stress curve for a medium until failure and (b) device used to test for yield stress and ultimate tensile strength. (Courtesy of Kerina Yin.)

Ultracentrifuge

[biomedical, mechanics] Rotating device used for molecular analysis. The centrifuge spins vials, ampoules, or test tubes containing SOLVENT with SOLUTES to separate the SOLUTE primarily by weight or size. The functional purposes of the ultracentrifuge can be categorized as follows: (1) determine the VISCOSITY of the solutes and hereby derive the shape and size of the MACROMOLECULES in the SOLUTION, (2) classify constituents on DENSITY, BUOYANCE and density gradient, and (3) characterize the respective MOLECULAR WEIGHTS of dissolved molecules. The specimen containers can be spun at ANGULAR VELOCITIES greater than $120,000 \pi \text{ rad/s}$, which amounts to the radial ACCELERATION equivalent of $260,000g$. Molecular weight can be determined by four different means: SEDIMENT VELOCITY, SEDIMENT EQUILIBRIUM, SEDIMENT EQUILIBRIUM IN A DENSITY GRADIENT, and ARCHIBALD APPROACH TO EQUILIBRIUM METHOD. The segregation and molecular distribution in the container are determined primarily by optical means. The three optical mechanisms that are used are the SCHLIEREN IMAGING for CONCENTRATION, RAYLEIGH SCREENING,

and straight forward OPTICAL ATTENUATION SCREENING. An additional mechanism uses RADIOACTIVE LABELING and counts the RADIOACTIVITY in the sediment with spatial RESOLUTION (see Figure U.5).

Figure U.5 Ultracentrifuge.

Ultrafast biological events

[biomedical, chemical, mechanics, optics] Certain biological phenomena are faster than they might appear. In VISION, it has been shown that in contrast to the slow overall phenomenological mechanism of vision there are events in ROD and CONE sensibility that take place in the femtosecond and even picosecond range. The vision experience itself is however in the 20–100 Hz range with a response time in the order of a few hundredths of a second for the various species. The physiochemical process of the PHOTOCHEMICAL EFFECT in the RETINA is in the same time-scale range as the PHOTOELECTRIC EFFECT for metals. *Also see PHOTOVOLTAICS/ PHOTOELECTRIC EFFECT and SOLAR PANELS*, where the use of biochemical processes generates substantial amounts of electrical potential. Other photobiological processes are at the cellular MEMBRANE level. In the purple bacteria (*Halobacterium halobium*), for instance, light can energize the TRANSMEMBRANE PROTON PUMPING on a femtosecond time scale. In biological cells, there are vibrational mode transitions, specifically in amino-acids, that take place on a femtosecond or shorter scale. Two important spectroscopic phenomena in biological functionality in the ultrashort timeframe are found in PHOTOSYNTHESIS and VISION. The LIGHT interaction in the RODS and CONES of the EYE (receptor protein: rhodopsin, CHROMOPHORE derived from vitamin A) takes place on a femtosecond scale. Rhodopsin is present in both rods and cones for vision. In vision, the QUANTUM states of the excited molecules yield information on the ENERGY transfer. One significant detectable interaction is $C_{11} = C_{12}$ isomerization, which reveals itself through torsional vibrations; specifically the low $C_{12} - H$ VIBRATION frequency in bathorhodopsin that shows anomalous behavior. The first chemical process is

associated with a transition defined by the Frank–Condon state, which has an approximate lifetime of 200 fs (see Figure U.6).

Figure U.6 Ultrafast biological effect. Graphical representation of the chemical response for rhodopsin, transforming into bathorhodopsin. The photon interaction with the associated energy deposition takes place in the first 50 fs of the chemical energy process, depicted on the far right of the graph; indicated by a Franck–Condon event. The spectral information imbedded is shown by the detected Raman emission “a” as well as the detected broadband restructuring fs event with a time-dependent energy profile in the transition “b.” The chemical transformation into bathorhodopsin takes place approximately 1–2 ps into the process. The molecular interaction exemplified by a vibrational process is most pronounced at $\lambda = 568$ nm.

Ultrafast phenomena

[general, solid-state] Ultrashort light pulses can be produced by LASER and more recently light-emitting diodes have accomplished a femtosecond pulse duration. Lasers can operate in MODE-LOCKED MODE, Q-SWITCHED, or COLLIDING PULSE MODE to create femto- and picosecond pulses. Most ultrafast phenomena apply to spectroscopic events, the formation and breakdown of chemical links, either by external excitation (ENERGY source), or in the transition from one state to another (see ULTRAFAST BIOLOGICAL EVENTS and FRANCK–CONDON EFFECT). The phenomenon itself is so fast that the process cannot be observed and can only be derived from related physical conditions and measurements.

Ultrahigh pressure

[atomic, general, geophysics, thermodynamics] The pressure range from 50 to 250 GPa. Under ultrahigh pressure conditions, the PHASE transitions take place on a atomic/molecular LATTICE structure level, for general rocks as well as the formation of diamond. One topic of specific interest is the formation of diamonds from carbon under high temperature and high pressure. Graphite will form into a “diamond” lattice under temperatures ranging from 400°C – 1800°C under respective pressures ranging from 2.5 to 65 Gpa, which can be under normal geological conditions at depths of 150 km and more.

Ultrasonic ablation

[biomedical, mechanics] SOUND waves have ENERGY associated with the time-dependent pressure ($P(t)$) fluctuations (and the associated harmonic changes in the density as a function of time (t): $\rho(t)$) as a function of location based on the INTERNAL ENERGY ($U(t) = (1/\rho)[P(t)/(\gamma - 1)]$, with $\gamma = (1 - [\mu_0/v_s]^2)^{-(1/2)}$, the Lorentz factor, with μ_0 the eddy speed for acoustic propagation and v_s the speed of sound) and the kinetic energy in the direction of interest (which is generally the direction of propagation, which can be in three dimensions) ($KE(t) = \iint (1/2)\rho(\tau)\vec{v}(\tau) \cdot \vec{v}(\tau) d\tau dV'$, for an infinitesimally small volume ELEMENT V' , small enough to be adiabatic and relatively constant). Where the pressure gradient between the crests and troughs provides a mechanism of flow (flow velocity: $\vec{v}(t)$), a potentially rotational flow since the phenomenon can be in a three-dimensional medium (SURFACE WAVES may also have TURBULENCE associated with the WAVE propagation in the three-dimensional medium, but the effects can generally be negligible). Note that the pressure applies a FORCE (F) on the virtual surface, with area A , in the medium of the wave propagation. The total energy provided from the transverse WAVE MOTION in the direction of propagation can be expressed as $\bar{E} \sim A * P' * \overline{v'}|_{\text{direction}}$, for an ISENTROPIC medium ($k_b(\partial T/\partial x_i) = 0$, where T is the temperature and $k_b = 1.3806488 \times 10^{-23} \text{ m}^2\text{kg/s}^2\text{K}$ the Boltzmann coefficient; and $P = \text{Const} * \rho^\gamma$) that is also considered to act as an ideal system (i.e., $\sigma_{ij} = -P\delta_{ij}$, where σ is the local Cauchy stress TENSOR at the plane with “coordinate” i in direction j ; and δ_{ij} the Kronecker delta). This acoustic energy can be applied by focused directional application in the ablation of, for instance, KIDNEY stones, known as lithotripsy. The vibrational energy will intentionally exceed the ULTIMATE TENSILE STRENGTH and the associated shear stress threshold: yield stress of the crystalline aggregate formed from minerals extracted from the digested food products (see Figure U.7).

Figure U.7 Ultrasonic ablation; lithotripsy.

Ultrasonic computerized tomography

[acoustics] Imaging process that resembles the mechanism of action for X-RAY computerized TOMOGRAPHY, using pressure WAVE transmission IMAGE formation, and SIGNAL processing based on a line integral of the attenuation on a propagation path. The main difference from ULTRASOUND with X-ray is that the pressure wave PHASE and transmission velocity can be used as a mechanism to localize the mechanical properties of interest at any point along the length of the propagation path of the SOUND wave. The advantage of transmission tomography is the ability to image bulk tissues, not just interfaces, as is generally the case for REFLECTION ultrasound imaging. Hard materials however can significantly block the acoustic transmission, if not at least cause refraction distortions. Some of the density and related Young's modulus information of

the transmission media is also imbedded in the spectral profile of the received signal, which is deconvolved by FOURIER ANALYSIS. Specific material structures, such as fiber structure, can additionally result in DISPERSION that provides material details but also provides distortions if not recognized as such. Ultrasonic computerized tomography is starting to form an alternative to mammography. Note that reflection pulse-echo ULTRASOUND imaging (as used to image for instance a baby in the womb) with an imaging array is also providing a tomographic image reconstruction (see [Figure U.8](#)).

Figure U.8 Three-dimensional reconstruction form of multiple slices of ultrasound scanning arrays. Most well known in the rendering for baby embryo or fetus in the womb. Specifically clear in the comparison between the ultrasound tomography of the baby just prior to birth and a real image captured a few days after birth. Often these images are real time and can display the motions made by the fetus in the womb. In comparison to traditional B-mode ultrasound.

Ultrasonic flow meter

[fluid dynamics] Flow meter based on DOPPLER shift. Designs are available in various shapes and sizes, ranging from a tubular probe that wraps around an artery to a hand-help probe for external flow assessment of a subcutaneous vessels flow (see DOPPLER) (see Figure U.9).

Figure U.9 Ultrasonic flow meter.

Ultrasonic imaging

[biomedical, mechanics] See ULTRASOUND.

Ultrasonic levitation

[general] Lifting an object by means of the force exerted by a JET of FLUID; related to aerodynamic levitation, since SOUND is a pressure wave. The acoustic ENERGY produces a flow of a medium with density ρ , and flow velocity v , that has its roots in the Bernoulli equation and the resulting FORCE (F) is equivalent to the time-averaged gradient in the flow direction ($\hat{x}$) for the kinetic energy density: $F = \partial/\partial\hat{x}(-\rho(v^2/2))$.

The force produced by a standing wave is obviously more powerful than a free-flowing stream. Generally, frequencies in the kHz range are sufficient to produce LEVITATION (see Figure U.10).

Figure U.10 (a,b) Acoustic levitation. (Courtesy of Mike Szczys.)

Ultrasonics

[acoustics, electronics, mechanics] Using ULTRASOUND; composed of a combination of compressional waves, fast shear waves, and slow shear waves; part of acoustic imaging (*see* ULTRASOUND). Ultrasonics can be used to determine the SHEAR STIFFNESS and SHEAR VISCOSITY of LIQUIDS. Machines using TORSIONAL and SHEAR-WAVE distortions measure the ACOUSTIC RESISTANCE also referred to as ACOUSTIC IMPEDANCE. The acoustic impedance implies that the medium has both elastic and viscous properties. Ultrasonics can be considered a component of nondestructive acoustic testing for flaws in materials. Ultrasonics also refers to the high-frequency probing of animals with reference to their orientation within a volume filled with obstructions as well as recognizing potential targets based on the FREQUENCY SPECTRUM acquired from a back-scattered SOUND, such as the one used by, for instance, bats and dolphins (see Figure U.11).

Figure U.11 Example of ultrasonic nondestructive testing.

Ultrasonograms

[acoustics, biomedical, imaging] Image obtained by ULTRASOUND imaging, primarily in medical diagnostics, also referred to as SONOGRAM.

Ultrasound

[acoustics, biomedical, general, mechanics] Rhythmic pressure disturbances that are beyond the audible range of human detection (range approximately 20–20,000 Hz, depending on the AGE of subject and other factors) for the higher frequencies (ν). Generally ultrasound is considered operating at frequencies of $\nu \geq 20,000$ Hz. The existence of acoustic (pressure-wave) frequencies above 20 kHz was discovered around 1780, but it was not until 1942 that KARL THEODORE DUSSIK (1908–1968), engineer and physician from Austria, used high-frequency pressure WAVE for medical imaging applications. Prior to this, ultrasound was used for detection of flaws in metallic structures in nondestructive quality control. Earlier applications of ultrasound were in echo location, specifically for underwater guidance. REGINALD FESSENDEN (1866–1932) patented the echo-location mechanism of action in 1912. Diagnostic ultrasound relies on the wavelength (λ) for RESOLUTION: $\lambda = \nu/\nu$, with ν being the speed of SOUND in the medium. The smallest items that can be resolved are in the order of half the wavelength in the longitudinal direction when used for imaging. The LATERAL RESOLUTION primarily depends on the acoustic array density (*also see* RAYLEIGH CRITERION and PHASED ARRAY). In diagnostic imaging using ultrasound, the frequency range is generally from 2.0 to 60 MHz. Higher frequencies will have a shallower penetration due to the increased attenuation ($\alpha(\nu)$) according to the relationship $\alpha(\nu) = \beta \nu^n$, where β is a material constant and $1 \leq n \leq 2$ is also a function of the medium in which the compression wave travels. The material constants β and n can be derived from a least square curve fit to the measured attenuation as a function of frequency. Ultrasound is used in biological imaging (e.g., SONOGRAM of fetus), nondestructive testing, and echo location (e.g., submarine navigation, radar as well as navigation used by BATS). In diagnostic use, both MACROSCOPIC and MICROSCOPIC, there are various sources available that can generate longitudinal ultrasonic waves. In medical imaging, the use of anisotropic ferro-electric ceramic crystals has the upper hand, namely piezoelectric transducers (e.g., quartz [one of the initial sources], barium titanate [BaTiO₃], lead zirconate [PbZrO₃], LEAD ZIRCONATE TITANATE [PZT] and lead titanate [PbTiO₃]). Other LONGITUDINAL WAVE sources are lithium niobate (LiNbO₃), lead metaniobate (PbNb₂O₆), zinc oxide (ZnO), polyvinylidene fluoride (PVDF), and Poly(vinyl alcohol) film, PVA. Zinc-oxide can generate frequencies up to 96 GHz. In piezoelectric materials, there is an inherent anisotropy combined with the DIELECTRIC properties of the crystalline structure that will change the crystalline structure under the influence of an external electric field, allowing it to unidirectionally compress under an applied electric potential. The crystalline displacement can be translated to an external medium, causing this medium to compress and expand at the same rate as the crystal subjected to an alternating voltage. The longitudinal pressure wave forms the basis of acoustic imaging or, on a more basic level, DISTANCE gauging. Any vibrating mechanism can produce ultrasonic waves; bats use specialized vocal chords. The acoustic wave traversing the medium will encounter objects that will diffract, scatter, and reflect the wave, in addition to discontinuities in density in general that create acoustic discontinuities in the speed of propagation of sound also known as the acoustic index-of-refraction. Changes in speed of propagation will also obey SNELL'S LAW for ACOUSTICS. High-energy ultrasound can also be used in a destructive mode. Kidney stones are routinely pulverized with the use of intense focused ultrasound, whereas industrial applications include carving and etching of metallics and ceramics and other solids. As a nondestructive testing tool, ultrasonic surface ACOUSTIC WAVES (SAWs) are used to identify anisotropic behavior indicating weaknesses, operating in the GHz range. A similar principle is used for seismologic characterization; in this case the devices are large mechanical tools or even operating under explosive charges.

Other ultrasonic applications are in destructive high-power use from a sonicator, typically operating at 600 W at frequencies around 20 kHz (see [Figure U.12](#)).

Ultraviolet

[optics] Part of the ELECTROMAGNETIC SPECTRUM recognized in 1801–1804 by the Prussian scientist (now Poland) JOHANN WILHELM RITTER (1776–1810) with wavelengths shorter than the visible blue; wavelength range: ~12 to 360 nm. The ultraviolet spectrum is subdivided in three regions, where the extreme ultraviolet (EUV) covers the range: ~12 to 130 nm, and borders X-RAY RADIATION; far ultraviolet covers 130–200 nm; mid UV: 200–300 nm, and near ultraviolet is the spectrum: 300–400 nm. Note that these are approximations and that definitions vary based on the specific field of use or research. Another classification is in the general ranges of ultraviolet, which is more regulated, defining UVC as 100–280 nm; UVB 280–315 nm and UVA in the span 315–400 nm. Ultraviolet in the UVA provides the ENERGY for the CELL to generate vitamin K and changes the chromophores to create a SUN tan. Human VISION ranges roughly from

330 to 660 nm; however, these are not sharp cut-off thresholds. Note that the PERCEPTION has a curve with trailing edges for the CONES on the blue and the RED side, as well as for the “green” cone. Certain animals can see well into the ultraviolet. Most bacteria can be killed by ultraviolet radiation in the range 260–300 nm; wavelengths shorter than 260 nm are even more effective (see [Figure U.13](#)).

Figure U.13 Ultraviolet, as used in tannin bed. Used in forensics for highlighting chemical components without the direct need for chemical analysis, such as revealing finger print by means of the resident oils.

Ultraviolet catastrophe

[atomic, energy, general, nuclear] The original attempts to model the ENERGY of electromagnetic RADIATION to wavelengths were based on a WAVE theory only, whereas the introduction of QUANTUM MECHANICS applying the energy conversion $E = h\nu = b(c/\lambda)$, with $b = 6.6256 \times 10^{-34}$ Js PLANCK'S CONSTANT, ν the frequency of radiation, $c = 2.997925 \times 10^8$ m/s the speed of LIGHT, and λ the wavelength showed the energy drop in black-body radiation at short wavelengths in contrast to the original EMISSION THEORY as described in the radiation theory introduced by MAX PLANCK (1858–1947). The original radiation theory would allow for an ever increasing energy with a decreasing wavelength emitted under excitation, for instance heat; the ultraviolet catastrophe. Since the original Rayleigh–Jeans theory describes unlimited energy to be generated under limited resources ($E = c\epsilon_B T/\lambda^4$, where $\epsilon_B = 1.38066 \times 10^{-23}$ J/K is the Boltzmann constant, T the temperature), the “catastrophe” was introduced as the energetic conundrum. Experimental observations showed a peak in emission wavelength as a function of temperature, but at shorter wavelengths the emission would drop. QUANTUM THEORY introduced a Boltzmann energy distribution that compensated for the ever increasing WAVE ENERGY with decreasing wavelength (see [Figure U.14](#)).

Figure U.14 Ultraviolet catastrophe.

Umbilical cord

[biomedical, chemical, fluid dynamics] Hemodynamic link between the placenta in the mammalian mother and the unborn offspring, containing a variety of stem-cell lines and a BLOOD BARRIER that will not allow different blood types of host and fetus to interact. The umbilical cord provides a means of separation by semipermeable membranes among other mechanisms. There are four different blood group phenotypes: O, A, B, and AB, with rhesus factor either positive or negative (Rh factor). Specifically, since certain blood types cannot mix and will result in instant death for the fetus if no preventative action is taken. Specifically, when the mother is Rh negative and the baby is Rh positive, complications may arise during childbirth if no preventative action is taken. Latin: umbilicus (navel). In aerospace and aviation terms, the umbilical cord refers to the combination fuel-line and control cabling that attaches to a rocket to the main station and is detached on takeoff (see [Figure U.15](#)).

Figure U.15 Umbilical cord, and the chemical exchange through the placenta in the female womb.

Unbestimmtheitsprinzip

[atomic, computational, general, nuclear, solid-state] See **UNCERTAINTY PRINCIPLE**.

Uncertainty principle

[atomic, computational, general, nuclear, solid-state] **QUANTUM** mechanical principle formulated by **WERNER KARL HEISENBERG** (1901–1976). In Heisenberg's words: "UNBESTIMMTHEITSPRINZIP" (German). The uncertainty principle entails that the observation of a phenomenon will influence the phenomenon, more specifically either the location (x) or the momentum (p) can be known, but not both with total accuracy, expressed in one-dimensional analysis as $\Delta p_x \Delta x \geq (1/2)\hbar$, where Δ identifies the uncertainty in the parameter, $\hbar = h/2\pi$, with $h = 4.13567 \times 10^{-15}$ eVs = 7×10^{-34} Js the Planck constant, or referred to by Max Karl Ernst Ludwig Planck (1858–1947) as "the quantum of action." The use of a **PHOTON** to identify a phenomenon or an object will be linked to the photon momentum $p = h/\lambda$. During the probing action, the photon may transfer all of its momentum to the object; however, the resulting momentum of the object will be

uncertain by an amount $\Delta p = h/\lambda$, whereas the location of the object can only be defined as accurate as approximately half a wavelength: $\Delta x \cong \lambda$. The uncertainty principle ties in with QUANTUM MECHANICS due to the fact that the product of the uncertainty in location and momentum (c.q. ENERGY $[E]$): conceptually $\Delta E \Delta x \geq (1/2)\hbar$ is finite and not zero. Under classical mechanics conditions, the speed of LIGHT would yield $c = \infty$ and the constant, at this point undefined, would be $\hbar = 0$. Uncertainty with respect to nuclear electrons; based on the general terms of the uncertainty principle that no electrons can exist inside the NUCLEUS based on the fact that the nucleus has a diameter in the order of $\Delta x = d = 1.0 \times 10^{-14}$ m, providing a kinetic energy $KE = 9.3$ MeV greater than any electron ACTIVITY related phenomena, meaning that the nucleus has too much energy content for an electron. In three-dimensional analysis of a WAVEFUNCTION (ψ), the uncertainty principle can be expressed as $\psi, (\mathbf{p} - \bar{\mathbf{p}})^2 \psi \psi$, and $(\mathbf{x} - \bar{\mathbf{x}})^2 \psi \geq 9\hbar^2/4$, where $\mathbf{p} = -i\hbar\nabla$ is the momentum operator, with $\nabla = \sum_{i=1}^n d/d\xi_i$ the Laplace operator, ξ_i denoting the DEGREES OF FREEDOM, $\mathbf{x}$ the position operator in the ξ space, $\bar{\mathbf{p}} = \psi, \mathbf{p}\psi$ is the average momentum, and $\bar{\mathbf{x}} = \psi, \mathbf{x}\psi$ is the average position. Note the DE BROGLIE WAVE for moving objects still applies. Generally under these conditions, the expected value for an observable parameter (X) (i.e., operator) is expressed as $\psi, X\psi = \int \psi(\mathbf{x})^* X\psi(\mathbf{x}) d^3\xi$ (see Figure U.16).

Figure U.16 Graphical illustration of the uncertainty principle: the observation of the location for a phenomenon is obscured by the momentum and associated velocity of the phenomenon. One cannot identify the location of a moving object due to the combined velocity and mass of the phenomena associated with the object.

Uncorrelated states

[thermodynamics] Generally ENERGY has an additive quality, where a system containing two or more subsystems will contain the sum of the energy of both subsystems. This also means that the encompassing system will contain all the states of the subsystems to form a composite system. Keeping this in mind, the states will be interrelated. In certain cases, the environment of the system will have states of its own, when the external states do not influence the internal states, and as such are isolated (and hence autonomous), they are considered uncorrelated. The uncorrelated states are hence impervious to the values of the properties of external systems, which is most often the general assumption in describing a physical phenomenon unless there is a direct exchange with the environment, which would imply that the environment is part of the system and is not a separate system. One rudimentary example is a thermos flask that is being uncorked, which connects the outside system.

Underdamped system

[general] OSCILLATION with a slow decreasing AMPLITUDE after the driving FORCE has been removed. The driving force generates a FORCED OSCILLATION. Even though a true underdamped system would be energetically unsupported, the closest examples are the free oscillation of a gong or a tuning fork. In theory,

the only underdamped system is the PHOTON, where perfect MONOCHROMATIC LIGHT has an infinite wavelength. Compare to CRITICALLY DAMPED, UNDERDAMPED, DAMPED SYSTEM, and OVERDAMPED system (*also see DAMPED OSCILLATION*) (see [Figure U.17](#)).

Figure U.17 Underdamped system of the photon, underdamped system of the gong or tuning fork.

Unequal-arm balance

[general] Weighing system that uses a torque as a means of equating the (gravitational) force multiplied by the arm length from an unknown mass against that of a known and calibrated mass and the respective arm length on the balance.

Unified atomic mass units (*u*)

[atomic, general, solid-state] One kilo MOLE of an ELEMENT of choice has a mass in kilogram that is by definition equal to the molecular mass of that element expressed in units *u*.

Unified Fourier reconstruction

[acoustics] Graphic reconstruction from ULTRASOUND data using unevenly spaced data SAMPLING values to shape the outlines of an object/perimeter of a boundary relying on interpolation. The spatial domain FOURIER TRANSFORM is adjusted for discontinuities as such revealing the discontinuities by adaptively spatially limiting the range over which the Fourier transform is composed.

Unified theories of the weak and electromagnetic interactions

[computational, electrodynamics, electromagnetic, general, quantum] Even though weak interactions (very large vector field $W^{//} = C_1 \vec{p}_e \cdot \langle \vec{J} \rangle + C_2$, with $\vec{p}_e$ the momentum vector of the electron distribution and $\vec{J}$ the charge POLARIZATION for the NUCLEUS, C_i constants, which apropos, are nonconservative with respect to PARITY) and electromagnetic interactions (PHOTON) there is a computational analogy between the two mechanisms in vectorial form.

Unified theory

[computational, dynamics, electromagnetism, general, quantum] In the theoretical description of weak and electromagnetic interactions, there are commonalities that transgress the interactions of massless photons versus extensive values for the mass-equivalent weak interactions found in leptons and hadrons. The scale at which this phenomenon gains importance is of the order of 1/1000th the size of a NUCLEUS. The WEAK INTERACTION is described as a weak-interaction density distribution ($\mathcal{L}_W$) with the Lagrangian formulated in vectorial quantities as $\mathcal{L}_W = -(G/\sqrt{2})J_\alpha^\dagger(x)J^\alpha(x)$, where $J^\alpha(x)$ represents the charge current, $J_\alpha^\dagger(x)$ the current equivalence for raising a charge in a transition such as from n state to p state, and G is the gravitational constant (see Figure U.18).

Figure U.18 Unified theory in graphical form. (Courtesy of James N. Imamura, University of Oregon, Eugene, OR.)

Universal gravitation, law of

[astrophysics/astronomy, general] See LAW OF UNIVERSAL GRAVITATION.

Universal gravitational constant (G)

[astrophysics/astronomy, general] Based on SIR ISAAC NEWTON's (1642–1727) deduction that gravitational attraction is directly proportional to the product of the masses (m_i) of the respective objects involved, and inversely proportional to the square of the separating DISTANCE (r), as described in his LAW OF UNIVERSAL GRAVITATION; he introduced a constant that holds true for all planetary gravitational interactions: $F = G(m_1m_2/r^2)$, with the universal gravitational constant $G = 6.6720 \times 10^{-11} \text{ Nm}^2/\text{kg}^2$.

Universe

[astrophysics, general, geophysics] Collection of all galaxies, containing solar systems and meteors and galactic dust resulting in what is currently believed to be the result of an explosion that occurred approximately 1.5×10^9 years ago. Currently, the Universe is consistently expanding supporting this theory, making

certain galaxies move away from us, whereas other galaxies that we move toward seem to gain on us. The knowledge supporting the EXPANDING UNIVERSE is based on data acquired by Hubble, and the Hubble TELESCOPE in outer space. These relative galactic movements can be verified by the red- and BLUE-SHIFT phenomena (regular and relativistic DOPPLER EFFECT). One major dilemma with respect to the “BIG BANG” THEORY is that this seemingly requires the generation of ENERGY out of “nothing” (*also see* **BIG BANG THEORY**) (see [Figure U.19](#)).

Figure U.19 The universe, artist impression and images acquired by the Hubble Space Telescope.

Unstable equilibrium state

[atomic, geophysics, solid-state, thermodynamics] State of medium that can spontaneously transition into another state, or series of cascading states with associated short-lived interactions. An example of a specific unstable equilibrium would be a supercritical NUCLEAR REACTOR, without NEUTRON. Introducing a single neutron will cause a sequence of events that can generate a substantial amount of ENERGY. Alternatively, an object that is supported above the CENTER OF GRAVITY (center of mass) will be in stable equilibrium, whereas when the object is supported below the center of gravity this will provide an unstable equilibrium (see [Figure U.20](#)).

Figure U.20 Energy diagram for an unstable equilibrium state.

Unsteady flow

[fluid dynamics] Flow process that involves discharge at the initial or final segment of the flow process. There are multiple inlet and outlet access routes that add or subtract from the flow process. Unsteady flow is a complex mechanism and requires computational fluid-dynamic analysis (see [Figure U.21](#)).

Figure U.21 Flow changing over time, due to the flow developing process based on the boundary conditions as well as the initial conditions or changing flow conditions due to perturbations. (a) Hydrodynamics simulation of the Rayleigh–Taylor instability. (Courtesy Shengtai Li, Hui Li; the U.S. Department of Energy.) (b) Streamlines for flow development with respect to onset of flow (e.g., wind gust).

Unsteady state

[thermodynamics] The state of a medium that changes due to interactions with other systems. One specific example of an unsteady state is the electric charging of a BATTERY; this will proceed until the battery is fully charged.

Up antiquark

[atomic, general, nuclear] Antiquark that has flavor “up” (*also see* UP QUARK).

Up quark

[atomic, general, nuclear] Quark that has FLAVOR “up” (*also see* ELEMENTARY PARTICLE). Quark with the following characteristics: charge: $+(2/3)e$; SPIN: $(1/2)\hbar$; BARYON NUMBER: $1/3$; strangeness: 0; CHARM: 0; bottomness: 0; and topness: 0 (*see* QUARK).

U-quark

[atomic, general, nuclear] *See* UP QUARK.

Uranium ($^{238}_{92}\text{U}$)

[atomic, nuclear] The most prevalent uranium ISOTOPE (99.275%), discovered in 1789. Uranium-238 is a stable isotope with a half-life of 4.5 billion years. Uranium-238 can be made into a FISSION product to generate ENERGY by bombardment with a NEUTRON, with subsequent two beta decays rendering plutonium-239, a nuclear component for fission used in explosive devices. U-238 is also used as a coating for bullets, providing them with armor-piercing capabilities. Also known as depleted uranium, reduced commercial value with respect to the naturally fissile uranium-235 (used in the first ATOMIC BOMB: “Little Boy,” 1945). Uranium 238 is a by-product of the uranium enrichment process of extracting U-235, occurring at ~0.7% in natural state, where U^{235} is fuel for nuclear power plants; at 3%–4% concentration (*see* Figure U.22).

Figure U.22 Uranium, ($^{238}_{92}\text{U}$), electron configuration; McArthur River Uranium Mine; drill core mineralized stable $^{238}_{92}\text{U}$ uranium; uranium ore (uraninite) from Příbram, Czech Republic.

Urey, Harold Clayton (1893–1981)

[atomic, nuclear] Chemist and physicist from the United States who performed pioneering work in ISOTOPE analysis. Harold Urey is best known for his discovery of the deuterium isotope of hydrogen in 1931. Urey received the Nobel Prize in Chemistry for his work in nuclear PHYSICS in 1934, specifically the principal mechanisms of NUCLEAR FUSION. Additional work was in the isolation of various isotopes, including carbon, nitrogen, and sulphur (see [Figure U.23](#)).

Figure U.23 Harold Clayton Urey (1893–1981). (Courtesy of Columbia University, New York.)

Taylor & Francis

Taylor & Francis Group

<http://taylorandfrancis.com>

V particles

[atomic, mechanics, nuclear, quantum] Generic name introduced in the 1940s describing unstable subatomic PARTICLE that, when undergoing its principle DECAY mechanism, will produce a pair of particles that are emitted in a v-form when observed in a BUBBLE CHAMBER. Since then these particles have been identified as MESON or BARYON particles (for instance, K-MESON and sigma-baryon) and the term v-particle has not been used anymore, but may still be found in reference material concerning the interaction of COSMIC RAYS with upper atmospheric conditions.

Vacuum

[general] Description of lower limit of pressure. Pressure by definition is the force per unit area for a volume that has an infinitesimal small surface area (A), expressed as $P = \lim_{A \rightarrow 0} (\rho g V / A)$, with the local density ρ , volume V , and GRAVITATIONAL ACCELERATION g . For vacuum $P \downarrow 0$, which means that for a finite volume the density shall approach zero, so that there are no intermolecular collisions possible that could yield a net force. Pressure in general was first measured in 1644 by one of GALILEO GALILEI's (1564–1642) assistants; the Italian scientist EVANGELISTA TORRICELLI (1608–1647) and this was expanded on by the French mathematician BLAISE PASCAL (1623–1662) in 1648, both man have their names associated with the units for the MAGNITUDE of pressure, specifically the “TORR” (1 torr = 1 mmHG; mercury) from Torricelli for low

pressure, and Pascal for ATMOSPHERIC PRESSURE and high pressure. Generally, the Pascal sets the standard for all pressure measures; 1 torr = 133.3 Pa (see Figure V.1).

Figure V.1 Vacuum; examples of conditions and applications of a pressure below atmospheric value. (a) outer space at deep (mm Hg) vacuum conditions, (sealed food with air removed to increase storage shelf-life) CRT scope tube with vacuum to increase electron flow conditions. (b) Suction pad used to attach to flat surfaces in order to facilitate lifting by means of the vacuum device.

Vacuum field equations

[astrophysics/astronomy, computational, optics] Description of gravitational interaction, including GRAVITATIONAL WAVES, and specifically the interaction with electromagnetic RADIATION known as Einstein's field equations under conditions at ABSOLUTE ZERO temperature, expressed as $\text{Ric} - (1/2)g_{\mu\nu}R + R_{\mu\nu}\Lambda = (8\pi/c^4)G\tau_{\mu\nu}$, where $\text{Ric} = R_{\mu\nu} = R_{\mu\nu}^v$ the Ricci curvature TENSOR; a contracted Riemann tensor ($R_{\mu\nu}^v$), which vanishes in VACUUM, $\tau_{\mu\nu}$ the stress ENERGY tensor, $g_{\mu\nu} = (\partial/\partial y^\mu)(\partial/\partial y^\nu)((1/2)F^2)$ the metric tensor derived from a matrix diagonal in Finsler structure (the metric tensor is directly linked to the Ricci factor, however with only half the number of independent components: 10) and F the Finsler structure; with property: $F(x, \lambda y) = \lambda F(x, y)$, operating in Finsler geometry, not Riemann geometry, subsequently: Λ the cosmological constant (the energy density of space vacuum, assuming a stationary universe), R the SCALAR curvature, G the gravitational constant, and c the speed of LIGHT. Einstein had to admit to an error in his assumption of the UNIVERSE, being an EXPANDING UNIVERSE, as revealed by EDWIN HUBBLE (1889–1953) in 1915; leading to a significant adjustment for the cosmological constant (Λ). Additionally, under the condition of absolute zero the energy density tensor ($\tau_{\mu\nu}$) drops to zero as well. Defined by ALBERT EINSTEIN (1879–1955), as part of his GENERAL THEORY OF RELATIVITY, in 1915.

Vacuum pump

[general] Mechanism used to achieve high VACUUM or ultra-high vacuum. High vacuum can be reached by a variety of methods with pressures down to 10^{-12} Torr $\sim 10^{-10}$ Pa. Vacuum can be achieved by rotary piston (roots pump), bellows pumps or reciprocating piston pumps; single (limit: 5×10^{-3} Torr) or

double stage (limit: 1×10^{-4} Torr). In order to reach a deeper vacuum additional techniques need to be incorporated, often applied in stages or in unison. High vacuum techniques include fluid jet, cryogenic means (GAS is frozen and hence removed), chemical reactions with solid residue, and IONIZATION with an applied electric field that forces the ions/polarized molecules out, with lower limit down to 1×10^{-8} Torr. For even lower pressure stages special techniques are required, such as a turbomolecular pump, reaching 1×10^{-10} Torr. Combinations of pumping techniques and potentially the introduction of cryogenic cooling and the assistance of helium or hydrogen can result in pressures as low as 1×10^{-12} Torr, operating at temperatures in the order of 10 K. Generally, the process of vacuum application will involve removing the gasses trapped in the WALL of the container as well, a process called “outgassing.” Outgassing may require heating the container. Proper material selection for the construction of the PUMP and container are crucial for ultra-low pressure consistency, seals in the junctions as well as in the pumps are all influencing the final outcome. Most vacuum chamber are constructed of high-grade stainless steel.

Valence

[atomic, general] The number representing the combining or displacing power of an ATOM; number of electrons lost, gained, or shared by an atom in a compound. The valence is the number of hydrogen atoms with which an atom will combine, or the number it will displace. Valence electron describes any electron which is gained, lost, or shared in a chemical reaction. Usually valence electrons are the outermost electrons in the BOHR ATOM model.

Valence band

[atomic, energy, general, quantum] Overlapping of ENERGY bands of individual atoms, creating a continuous energy band instead of discrete energy levels as described by the Bohr model. Electrons that move beyond the valence band into the CONDUCTION BAND are free to move. The valence band can provide a mechanism for sharing of the outermost electrons in this shared energy band, specifically in a CONDUCTOR; whereas in a semiconductor or INSULATOR the valence electrons are held close by the respective atoms. For an insulator the conduction band and valence band are separated by an energy gap greater than 10 eV, whereas for a semiconductor the separation is 1 eV or less. For a semiconductor the conduction process can be facilitated by DOPING, for instance introducing GALLIUM in silicon introduces a shared energy band that provides an escape mechanism for electrons bound to silicon, leaving holes in the silicon (i.e., POSITIVE CHARGE surplus) (see Figure V.2).

Figure V.2 Valence band concept illustrated by means of energy configuration for a hypothetical atom.

Valve

[fluid dynamics, thermodynamics] Closure mechanism applied to pipes and junctions in order to regulate the flow of fluids. Many types of valves exist, geared to achieve a specific goal or ease of use. Examples of

valves in use are butterfly, ball, gate, globe (one of many type found in water faucets as well as other applications), GATE VALVE or check valve. The flow control mechanism can depend on a seal or gasket made, for instance, out of rubber or cork, or can be METAL-on-metal with a through-hole that can be made to misalign. Check valves were common in the airflow regulation in older model automobiles with GAS MIXTURE supplied by a carburetor system, controlling the ANGLE of the flap that determines the opening area by depressing the gas pedal that connects through a level system (see Figure V.3).

Figure V.3 Various valve designs.

Valves closure, Allievi's equations

[fluid dynamics] Equation of MOTION for flow and EQUATION OF CONTINUITY defined in 1925 by the Italian mechanical engineer LORENZO ALLIEVI (1856–1941) with specific relevance to the “WATER HAMMER” effect. The equation of motion is defined by the flow (Q ; [m^3/s]) and the change in height (h , also for instance associated with a diverging tube) as $Ag(dh/dx) + (\partial Q/\partial t) + kQ|Q| = 0$, where g is the GRAVITATIONAL ACCELERATION, A the cross-sectional area of the tube, and k is the equation of continuity reads $(\partial h/\partial t) + (v_{ch}^2/Ag)(\partial Q/\partial x) = 0$, where v_{ch} is the rate of change in flow (for instance, due to closure), or the velocity of propagation. Both are also found as $(\partial v/\partial t) + (1/\rho)(\partial P/\partial x)$, where the velocity v is the velocity parallel to the PIPE axis and averaged over the CROSS SECTION, P the pressure, and ρ the density of the FLUID. Alternatively, $E_Y(\partial P/\partial t) + (\partial v/\partial x)$, with E_Y the effective COMPLIANCE for the system.

Van Allen, James Alfred (1914–2006)

[astrophysics/astronomy, electromagnetism] Astrophysicist from the United States, specifically known for his discovery of the toroidal charged-particle bands encapsulating Earth: the VAN ALLEN BELTS (see Figure V.4).

Figure V.4 James Alfred Van Allen (1914–2006). (Courtesy of North American Space Agency [NASA], Washington, DC.)

Van Allen belts

[astrophysics/astronomy, electromagnetism] PLASMA belts around EARTH. The two torus shaped zones of energetic particles (primarily electrons and protons) emit RADIATION discovered and described by the astrophysicist from the United States, JAMES ALFRED VAN ALLEN (1914–2006). The belts represent particles that are “trapped” in the earth’s MAGNETIC FIELD configuration. The existence of the belts was confirmed by the spaceship Explorer I in 1958. The Van Allen radiation belts form part of the mechanism leading to the AURORA BOREALIS. The Van Allen radiation belts form a protection from the sun’s radiation and are formed resulting from the collision SHOCK WAVE of the sun’s SOLAR WIND with the earth’s magnetic field. Also known as the Van Allen radiation belts (see [Figure V.5](#)).

Figure V.5 (a,b) Van Allen belts.

Van de Graaff, Robert Jemison (1902–1967)

[general] Scientist, experimental PARTICLE physicist from the United States. Robert van de Graaff constructed the first belt-operated (electrostatic) charge GENERATOR in 1931 (see [Figure V.6](#)).

Figure V.6 Robert Jemison van de Graaff (1902–1967). (Courtesy of Massachusetts Institute of Technology, Cambridge, MA.)

Van de Graaff generator

[atomic, energy, nuclear] Static charge generator and collection station using a conveyor belt to transport charges that are generated by a high potential source, generating the equivalent to a CATHODE ray, positioned close to an insulating moving belt. The moving belt enters a hollow CONDUCTOR, while in contact with the sphere by means of a wire brush, transferring the charges on the belt to create a relatively high electric potential on a the hollow sphere over time, which is a function of the time and the radius of the sphere (generally several hundred thousand volts; see COULOMB'S LAW). The Van de Graaff generator was designed by ROBERT VAN DE GRAAFF (1902–1967) in 1931 to examine the conditions of high electrical potential and electric discharge. Static charge had been known for millennia prior to this invention, rubbing AMBER with

fur to generate a static charge, dating back to 600 BC recorded by the Greek astronomer Thales (Thales of Miletus: ca. 624–546 BC) (*also see* **WIMSHURST MACHINE**) (see [Figure V.7](#)).

Figure V.7 Van de Graaff generator design, with Robert van de Graaff (1902–1967) operating the charge conveyor belt. (Courtesy of Massachusetts Institute of Technology, Cambridge, MA.)

Van der Meer, Simon (1925–2011)

[general] Scientist from the Netherlands, who together with the Italian scientist Carlo Rubbia (1934–), led a team of scientists to the discovery of the “intermediate vector bosons” (in particular the W and Z bosons) in 1983, for which they received the Nobel Prize in Physics in 1984 (see [Figure V.8](#)).

Figure V.8 Simon van der Meer (1925–2011). (Courtesy of Conseil Européen pour la Recherche Nucléaire [European Council for Nuclear Research]. Copyright CERN, Geneva, Switzerland.)

Van der Pol, Balthasar (1889–1959)

[electromagnetism, theoretical] Electrical engineer from the Netherlands who recognized the characteristic NOISE in VACUUM tubes while operating under an alternating current of specific driving frequencies (see [Figure V.9](#)).

Figure V.9 Balthasar van der Pol (1889–1959). (Courtesy of International Telecommunication Union (ITU), Geneva, Switzerland.)

Van der Pol equation

[biomedical, electromagnetism, geophysics, mechanics] Second-order differential equation describing the damped OSCILLATION in a dynamic system that is not subject to CONSERVATION OF ENERGY. $(d^2x/dt^2) - \epsilon(1-x^2)(dx/dt) + x = 0$, where x can be a location or other time-dependent variable, t is time, ϵ is a coefficient indicating COMPLIANCE (including system nonlinearities) and dampening, specifically $-\epsilon(1-x^2)(dx/dt)$ is the definition of RESISTANCE or FRICTION. In case $-\epsilon(1-x^2)(dx/dt)$ is negative positive the term applies to “negative resistance” and applies, for instance, to the gain (nonlinear) of a power amplifier. This equation is also used in biological application to describe the ACTION POTENTIAL of neurons in a planar field geometry, other relevant uses are in SEISMOLOGY to model the MOTION of TECTONIC PLATES at a FAULT LINE and to describe RESONANCE phenomena in compliant media, such as in NONDESTRUCTIVE TESTING using ACOUSTICS. The equation will need to solved numerically with for instance specialized segmented methods as described by the RUNGE–KUTTA METHOD.

Van der Pol oscillator

[biomedical, electromagnetism, geophysics, mechanics, theoretical] An OSCILLATION (primarily electric, but additional applications in MECHANICS and geophysics are supported) which is nonlinearly damped and as such inherently nonconservational (*also see* OSCILLATION). A forced Van der Pol oscillator is described by $(d^2x/dt^2) + \epsilon(x^2-1)(dx/dt) + x - A\sin(\omega t) = 0$, where x is a Cartesian coordinate, t is time, ϵ is a coefficient indicating COMPLIANCE (including system nonlinearities) and dampening, $A\sin(\omega t)$ is the driving alternating source with AMPLITUDE A , and frequency $2\pi\omega$.

Van der Waals, Johannes Diderik (1837–1923)

[atomic, solid-state, thermodynamics] Physicist and engineer from the Netherlands whose main contribution to SOLID-STATE PHYSICS was the description of medium-range attractive forces, the VAN DER WAALS FORCE (also described as VAN DER WAALS BONDING). Van der Waals made significant theoretical contributions to the description and understanding of the EQUATION OF STATE of gases and liquids, some substantial contributions were in his doctoral thesis. In 1910 Johannes van der Waals was awarded the Nobel Prize in Physics (see [Figure V.10](#)).

Figure V.10 Johannes Diderik van der Waals, (1837–1923). (Courtesy of Collection of the Van der Waals family.)

Van der Waals bonding

[biomedical, condensed matter, dynamics, general, nuclear, quantum, solid-state, thermodynamics] Also referred to as VAN DER WAALS FORCE. The force between molecules. This force distinguishes itself from the other known molecular forces defined as ELECTROSTATIC FORCE, covalent attraction, and hydrogen bonds. The Van der Waals force is a MACROSCOPIC force balance primarily applying to dipoles, both permanent and induced. Van der Waals forces act between molecules within the same structure, but also across an interface between different species of molecules such as at a surface, and work between atoms. The force is primarily derived from the fact that the atoms and molecules become charge polarized, the balance of negative and POSITIVE CHARGE shift to opposite sides respectively and forms an induced DIPOLE with limited lifetime or applies to permanent dipoles. The electrostatic interaction is also known as KEESOM FORCE. Groups of molecules can form charge distributions that lead to attractive force due to DISPERSION of the combined

charges forming multipoles. Examples of clear Van der Waals bonds are for instance found for graphite and clay (see [Figure V.11](#)).

Van der Waals force

[atomic] See VAN DER WAALS BONDING.

Van Helmont, Johannes (Jan) Baptista (1579–1644)

[general] Alchemist from the Netherlands attributed with the formal introduction of the concept of GAS as a material PHASE, not as a unique phenomenon (see Figure V.12).

Figure V.12 Johannes (Jan) Baptista van Helmont (1579–1644) c. 1674, painted by Mary Beale.

Van Laar equations

[thermodynamics] Description of mixtures with molar fractions of the (r -) constituents (μ^{mol}_i ; this forces $\sum_{i=1}^r \mu^{\text{mol}}_i = 1$). The van Laar equations are pertaining to binary mixtures specifically, yielding: $\ln \gamma'_1 = \ln \mu^{\text{mol}}_1 + (A/RT)/[1 + (A\mu^{\text{mol}}_1/B(1 - \mu^{\text{mol}}_1))]^2$ and $\ln \gamma'_2 = \ln(1 - \mu^{\text{mol}}_1) + (A/RT)/[1 + (B(1 - \mu^{\text{mol}}_1)/A\mu^{\text{mol}}_1)]^2$, where $A = \Delta H_{1,\text{mix}}$ and $B = \Delta H_{2,\text{mix}}$, with $H_{i,\text{mix}}$ the enthalpy of the constituent, and $\gamma'_1 = \gamma'_1(T, P, \mu^{\text{mol}}_1, \mu^{\text{mol}}_2, \dots, \mu^{\text{mol}}_{r-1})$ is the ACTIVITY of the ingredient (defining the excess in chemical potential relative to the state at reference pressure P_0 while at the same temperature) as a function of PRESSURE (P) and TEMPERATURE (T); however, not dependent on chemical composition.

Van Leeuwenhoek, Antonie Philips (1632–1723)

[biomedical, optics] Scientist, engineer, and merchant salesman from the Netherlands. Perfected the compound MICROSCOPE, reaching magnifications of 500X. Van Leeuwenhoek investigated biological materials such as bacteria, muscles, and spermatozoa. He also used his optical instrumentation to IMAGE

the **PERFUSION** of superficial vasculature and described capillaries. Considered the “father” of microbiology (see [Figure V.13](#)).

Figure V.13 Antonie Philips van Leeuwenhoek (1632–1723), painted by Jan Verkolje.

Van Musschenbroek, Petrus (1692–1761)

[energy, general] Physicist and mathematician from the Netherlands, instrumental in the development and experimental observations leading to the discovery of stored charge and the **CAPACITOR** (see [Figure V.14](#)).

Figure V.14 Petrus (Pieter) Van Musschenbroek (1692–1761), painted by Hieronymus van der Mij. (Courtesy of Leiden, Universiteits-Bibliotheek, Icones 147; Leiden, the Netherlands.)

Van Royen, Willibrord Snel (1591–1626)

[optics] See **SNEL** (“**SNELL**”), **WILLEBRORD SNEL VAN ROYEN** (**SNELLIUS**) (1591–1626).

Van't Hoff, Jacobus Henricus (1852–1911)

[biomedical, chemical, thermodynamics] Scientist and chemist from the Netherlands. Johannes van't Hoff received the Nobel Prize in Chemistry in 1901. One of Van't Hoff most memorable contributions is the definition of partial pressure of a dissolved solution as the OSMOTIC PRESSURE: $\Pi_{\text{osmotic}} = P - P_{jj} = (RT/v_{jj}) \sum_{k \neq j} \mathcal{Y}_k$, with $\mathcal{Y}_k = n_k/n = (x_k/M_k)/(\sum_{\ell=1}^r (x_\ell/M_\ell))$ the mole fraction of the dissolved constituent $_k$, with M_ξ the mean MOLECULAR WEIGHT OF SOLUTE $_\xi$, for the amount of constituent n_k summing to a total of solutes $n = \sum_{k=1}^r n_k$, x_ξ the fractional mass for constituent $_\xi$, P_{jj} the molar partial pressure of constituent $_j$ in SOLUTION, v_{jj} the volume of the INCOMPRESSIBLE FLUID per mole, PRESSURE P and TEMPERATURE T , and $R = 8.3145 \text{ J/molK}$ is the universal gas constant (see Figure V.15).

Figure V.15 Jacobus Henricus van't Hoff (1852–1911).

Van't Hoff equation

[biomedical, chemical, thermodynamics] Equation defining the pressure resulting from the gradient in concentration of solutes across a DISTANCE or a more physical BARRIER such as a SEMIPERMEABLE MEMBRANE. The Van't Hoff equation was defined by JACOBUS HENRICUS VAN'T HOFF (1852–1911), and is sometimes associated with the Starling equation. The OSMOTIC PRESSURE of a SOLUTION has the same value as if the particle solution would have as a GAS with the same volume and temperature as the solution. The OSMOTIC PRESSURE (Π_{osm}) can be expressed in the form used by the ideal gas law: $\Pi_{\text{osm}} = nRT/V = [C]RT$, where $R = 8.135 \text{ J/molK}$ is the gas constant, T the local temperature in Kelvin, n is the quantity of solutes in mol, and $[C]$ the concentration. The osmotic pressure is also referred to as the COLLOID OSMOTIC PRESSURE. Note that all solutions will add to the sum of the osmotic pressure of the LIQUID.

Van't Hoff factor

[fluid dynamics, geophysics, thermodynamics] Osmotic coefficient that applies to the partial pressure (Π_{osm}) of a SOLUTE described by the VAN'T HOFF EQUATION: $\Pi_{\text{osm}} = \Phi_{\text{osm}} RT \Delta[C]$, with $\Delta[C]$ the concentration gradient across a SEMIPERMEABLE MEMBRANE, where $R = 8.135 \text{ J/molK}$ is the GAS constant and T the local temperature in Kelvin. The expression $n_{\text{ion}} \times \Phi_{\text{osm}}$, where Φ_{osm} the osmotic coefficient or Van't Hoff factor, n_{ion} the number of ions respectively the solute concentration; yields the physically dissolved concentration contributing to the OSMOTIC PRESSURE. For NaCl (SALT) $\Phi_{\text{osm}} = 0.93$. Note that for electrolytes the Van't Hoff factor < 1 , however for nonelectrolytes the SOLUTION of particles becomes convoluted and complicated, rendering Van't Hoff factors < 1 , for instance, for hemoglobin the Van't Hoff factor $= 2.57$.

Van't Hoff law

[biomedical, chemical, thermodynamics] See **VAN'T HOFF EQUATION**.

Vapor

[thermodynamics] Material phase of a medium where the molecules or atoms are spaced relatively far apart, generally achieved when exceeding the boiling point for the material, a gaseous phase. Note that a solid may transform into GAS under **SUBLIMATION** ("steam" rising from ice). The heat of vaporization (h_v , or **LATENT HEAT OF VAPORIZATION**, based on the constant temperature of the process) defines the **ENERGY** required to convert 1 kg of liquid phase into vapor at constant temperature. Water vapor is referred to as steam. The phases of a material are represented by the **PHASE DIAGRAM**. At the **TRIPLE POINT** (three phase): solid, liquid, and gas/vapor exist at the same time under the same conditions in equilibrium. When a vapor cannot be described as an **IDEAL GAS** the Van der Waals equation needs to be used, specifically when the vapor is a dense mixture. The reverse **PHASE TRANSITION** process is condensation from vapor to **LIQUID**, or from vapor to solid **desublimation**, respectively (see [Figure V.16](#)).

(a)

(b)

Figure V.16 (a) Vapor for boiling water and (b) vapor in the refrigeration cycle for freon or other cooling liquid.

Vapor pressure

[nuclear, thermodynamics] The pressure of a vapor in equilibrium with its condensed state (**LIQUID** or **SOLID**). The vapor pressure of a medium (P_v) is defined by the **Clausius–Clapeyron equation**: $\ln P_v = -(\Delta H_v/RT) + (\Delta S_v/R)$, where H_v is the enthalpy of vaporization, S_v the entropy of vaporization, T the local temperature, and $R = 8.3144621(75)$ J/Kmol the universal gas constant. The vapor pressure of mercury is of particular importance with respect to its use as an **ENERGY** transferral in certain types of nuclear power plants, primarily due to the toxicity of mercury. Other examples of **METAL** coolants are sodium, lead, and tin.

Vapor pressure equation

[atomic, fluid dynamics] See **CLAUSIUS–CLAPEYRON RELATION**.

Variable capacitor

[general] Plate capacitor with variable surface area, primarily used as a tuning mechanism for radios in the late 1900s. The change in surface area (A) directly influences the value of the CAPACITOR (C) as $C = \epsilon A/d$, where ϵ represents the permittivity of the medium between the plates and d the plate separation (generally, the tuning plate capacitor has multiple plates). The capacitance determines the RESONANCE FREQUENCY of the RC circuit (resistor (R)-capacitor (C) circuit, with specific time constant: $\tau_c = RC$); hence providing a mechanism of influencing the PHASE-LOCKED LOOP that will collect only the RADIO signal that matches the resonance frequency of the tuner (see Figure V.17).

Figure V.17 Variable capacitor used for tuning an early model analog radio design.

Variable resistor

[general] Electrical device that can be adjusted for total resistance by means of rotation of a dial, which generally changes the length of a wire (ℓ) that the current passes through, hence changing the RESISTANCE since the SPECIFIC RESISTANCE ($\rho_{R, \text{spec}}$) of a METAL wire is a function of length: $R = \rho_{R, \text{spec}} \ell$. Also referred to as POTENTIOMETER (see Figure V.18).

Figure V.18 (a) Variable resistor, (b) potentiometer, and (c) circuit diagram icons.

Variance (σ^2)

[computational, quantum, signal, thermodynamics] The square of the standard deviation for a series (with sample size: N) of measurements (x_i), defined as $\sigma^2 = 1/(N-1) \sum_{i=1}^N (x_i - \bar{x})^2$, with the mean: $\bar{x} = 1/N \sum_{i=1}^N x_i$. The variance provides an indication of the physical spread in data, how far are the data removed from the mean value, and hence is an indication of risk. A large variance is an indication of a broad spread of the measured values, not particularly correlated to the likelihood (probability distribution), more an indication of how far out can numbers enter into the analysis with respect to the mean value.

A variance close to zero is an indication of a very close grouping of data. Additionally, variance is one of the moments of a distribution. The standard deviation for a sample distribution is the square root of the variance. In THERMODYNAMICS the concept of “variance” (F_{var}) relates the PHASE change of a chemical reaction to the number of coexisting phases of a system with r constituents defined as $F_{\text{var}} = r + 2 - q - \tau_{\text{ch}}$, where q is derived from the Gibbs PHASE RULE as the system operating in a q -phase state (heterogeneous stable equilibrium of coexisting phases; allowing each phase to be modeled as a simple system), and τ_{ch} represents the ordered number of potential chemical reactions, τ_{ch} is captured as a series (two constituents can have maximally one reaction, yielding $\tau_{\text{ch}} = 0,1$) (see Figure V.19).

Figure V.19 Statistical variance.

Vector boson

[general] Bosons that are the exchange particles in a weak nuclear interaction, in particular the W and Z bosons. The WEAK INTERACTION delineates the interaction between electrons and neutrinos.

Vein

[biomedical] Anatomical feature, BLOOD vessel that is returning blood to the HEART. Blood in the veins is generally oxygen poor, except for the veins carrying blood from the lungs, which is oxygen rich. Veins have valves in intermittent locations to prevent blood from pooling and flowing back due to the lack of applied pressure. Veins are fairly similar to arteries, with the exception that the veins do not have a muscular WALL and rely on externally applied pressure from SKELETAL MUSCLE to provide the pumping action, mediated by the valves to force the flow in the direction of the heart (see Figure V.20).

Figure V.20 Vein, blood vessel.

Velocity ($\vec{v}$)

[acoustics, biomedical, biophysics, dynamics, electromagnetism, engineering, general, geophysics, optics, ultra-fast phenomena] (syn.: speed) {use: energy, motion} Vector describing the MAGNITUDE and direction of the change in location (i.e., displacement) as a function of time: $\vec{v} = dL(x(t), y(t), z(t))/dt$, where $L(x(t), y(t), z(t))$ is the position in the three-dimensional Cartesian coordinate system as a function of time t .

Velocity potential

[fluid dynamics, geophysics] A dynamic function that has many similarities with potential theories of attraction (e.g., potential ENERGY), ELECTRICITY and magnetism, and ELECTROSTATICS (e.g., electrical potential). The velocity potential defined by the energy involved in FLUID flow moving from a fixed point A^* to variable point P^* is for an irrotational MOTION defined as $\phi = -\int_{A^*}^{P^*} (u dx + v dy + w dz)$, where in CARTESIAN COORDINATES $u = -(\partial\phi/\partial x)$ is the velocity in the x -direction, $v = -(\partial\phi/\partial y)$ is the velocity in the y -direction, and $w = -(\partial\phi/\partial z)$ is the velocity in the z -direction. For a VORTEX motion the velocity potential needs to include directional information defined by $\psi = \int_{A^*}^{P^*} (\chi_x \cos \Theta_x u + \chi_y \cos \Theta_y v + \chi_z \cos \Theta_z w) ds$, where $\cos \Theta_i$

described the respective **ANGLE** for all velocities with respect to the normal to the curved velocity profile and χ_i is a proportionality constant. The velocity gradients are now defined by $dw/dz = ((\partial\phi/\partial x) + (\partial\phi/\partial y)) + i((\partial\psi/\partial x) + (\partial\psi/\partial y))$, respectively, and so on. In turn the velocity profile for rotational flow is now defined by $\phi = (\kappa/4\pi) \iiint (\chi_x \cos \vartheta_x (\partial/\partial x') + \chi_y \cos \vartheta_y (\partial/\partial y') + \chi_z \cos \vartheta_z (\partial/\partial z')) (1/r) ds'$, where $\kappa = \varpi' \sigma'$ is a measure of the strength of the vortex with ϖ' an indication of the vorticity and σ' a **SURFACE ELEMENT ON THE VORTEX** filament, s' denotes the surface bounded by the vortex element, and $r = \sqrt{(x - x')^2 + (y - y')^2 + (z - z')^2}$ with (x', y', z') the location on the surface bounded by the vortex filament of importance and (x, y, z) the location in P^* where the velocities (u, v, w) will need to be derived. The work (W) done by rotational motion of an incompressible **LIQUID** can be related to the velocity profile (in accordance with general potential theories) as $W = (1/2)\rho \iiint [(\partial\phi/\partial x)^2 + (\partial\phi/\partial y)^2 + (\partial\phi/\partial z)^2] dx dy dz$ (see **Figure V.21**).

Figure V.21 Velocity potential for the geographic wind flow, averaged over 1 year. (Courtesy of University of Reading, Reading, UK; European Centre for Medium-Range Weather Forecasts [ECMWF].)

Ventilation

[biomedical, fluid dynamics, mechanics] Expansion and contraction of the chest cage coinciding with respective inspiration and expiration, known as breathing (*also see* **RESPIRATION**).

Ventilator

[biomedical, chemical, electronics, fluid dynamics, mechanics] Mechanical device providing an assist function to transport oxygen into the lungs by forcing **AIR** into the lungs by a **PUMP** mechanism. Ventilators are required during anesthesia since the normal muscular action that facilitate the volume **EXPANSION** of the lungs (inhaling) by means of either pulling down the diaphragm in the stomach by contraction (the diaphragm in relaxed state is curved upward), or elevating the ribs in the rib cage is rendered inoperable. Exhaling is an elastic process and relies on the **ANATOMY** to return to the position with the lowest **ENERGY**. In addition to mechanical ventilators that operate at the same frequency as with respect to unchallenged **ACTIVITY** for the person in question, other mechanisms are required as well. The **VENTILATION** process for premature babies is challenging to the extremely small size of the infants, size of a fist. In some cases the

use of high-frequency modulation is used to induce a net flow, operating under kHz acoustic perturbation. The high-frequency approach provides a minimal net force/pressure to the lungs of the infant, thus preventing damage to the lungs resulting from excessive force (see [Figure V.22](#)).

Figure V.22 Neonatal baby connected to special design ventilator specifically designed for the small tidal volume and respiratory rate boundary conditions.

Venturi, Giovanni Battista (1746–1822)

[fluid dynamics] Engineer and scientist from Italy who described the “suction” aspect of flow when passing through a narrowing tube with a hole in the wall of the tube in 1791 (see [Figure V.24](#)).

Figure V.24 Giovanni Battista Venturi (1746–1822).

Venturi

[fluid dynamics] Mechanical configuration with respect to flow that results in an increase in flow velocity with a resulting drop in pressure, based on Bernoulli's law. Two boats that are traveling side by side will cause a localized increase in flow velocity due to the narrowing passage between the boats (specifically due to the curved outer hull of the ships), which will force the boats to move closer together due to the undisturbed pressure experienced on the hull of the boats on the perimeter. Another example is the flow of water over a container with chemical SOLUTION, drawing the chemical solution into the flow stream as a result of a venturi with an appropriately placed opening connecting to the reservoir. This mechanism is used to

facilitate the diluted and controlled spread of fertilizer or weed killer. The physical process of creating “suction” by means of flow is referred to as the venturi effect. The process is named after the Italian scientist GIOVANNI BATTISTA VENTURI (1746–1822) who described this phenomenon in 1791. The venturi effect is also responsible for creating the mechanical MOTION of loose tissues in the nose and throat (airways in general) resulting in the snoring SOUND (see [Figure V.23](#)).

Figure V.23 Asthma inhaler with venturi for drug distribution: nebulizer.

Venus

[astrophysics/astronomy, general] Second PLANET from the SUN with an average diameter of 12,103.6 km, a mass of 4.86732×10^{24} kg, and an average surface temperature of 480°C. One SPIN revolution takes 243 Earth days, in the opposite direction with respect to earth’s rotation, and the revolution around the Sun lasts 225 Earth days. The Magellan space mission has explored Venus with great detail, and a total of 40 spacecraft have been sent to Venus so far (see [Figure V.25](#)).

Figure V.25 Venus.

Verlet method

[computational] Numerical integration technique, specifically designed to solve Newton's EQUATIONS OF MOTION, based on a TAYLOR EXPANSION with respect to the coordinates, introduced by the French physicist Loup Verlet (1931–) in 1967.

Versorium

[general] Elementary ELECTROSCOPE. One of the first devices used to measure static charge. The versorium was invented by the English astronomer and physician SIR WILLIAM GILBERT (1544–1633) around 1600 (see [Figure V.26](#)).

Figure V.26 Electroscope that uses the same principle as the versorium, a rod that can pivot freely. The original versorium had a close similarity to a compass needle, only for charge (i.e., electric field) and not for magnetic field. The illustrated gold-leaf electroscope was developed almost two centuries later, in 1787, by the clergyman and physicist Abraham Bennet (1749–1799) from Great Britain, following the introduction of the A pith-ball electroscope, which was a ball suspended from a thread, invented in 1754 by school teacher and physicist John Canton (1718–1772) from Great Britain, inspired by Benjamin Franklin (1706–1790) from the United States.

Vesalius, Andreas (1515–1564)

[biophysics, general] Scientist from Belgium describing the first documented dissection of the human ANATOMY: *Humani Corporis Fabrica* in 1543. This was a dissention from the Galenian school of biological

investigation (see **CLAUDIUS GALENUS** [130–201] also named “Galen”), focusing on animal observation and bodily composition examination (see **Figure V.27**).

Figure V.27 (a) Andreas Vesalius (1515–1564). (Courtesy of UCL Media Services; Collection: University College London Hospitals, London, Great Britain, example of the anatomic artwork by Andreas Vesalius.) (b) Epitome of Vesalius, Basel, 1543. (Courtesy of University of Glasgow Library, Special Collections; Glasgow, UK.)

Vibration

[acoustics, mechanics, solid-state, thermodynamics] Rhythmic motion with respect to a point of equilibrium, often with fixed frequency. Vibrations can be rotational (including “scissor action”), linear/translational, and “spherical” (general three-dimensional) EXPANSION, and are generally not confined to any single dimensional orientation; for instance, a drum SKIN, or GUITAR casing (acoustic guitar) can have a variety of oscillatory modes. The acoustic vibration, pressure wave, generates sound. Vibrations require an ENERGY source to support the MOTION, when the source is removed the OSCILLATION will dampen based on the elastic modulus of the medium. Vibrations supported by an external FORCE (F) obey the WAVE EQUATION with respect to the displacement $u(\vec{r}, t)$ as function of location $\vec{r}$ and time t : $\nabla^2 u(\vec{r}, t) = (1/v_s^2)(\partial^2 / \partial t^2)u(\vec{r}, t) - F$, where the displacement wave propagates through the medium with velocity v_s , the speed of SOUND for an acoustic wave (∇^2 is the Laplace operator, defining a second-order derivative with respect to location). Whistling generates a vibration with virtual single frequency, described by a sinusoidal function for the AMPLITUDE: $A(t) = A_0 \sin(\omega t - \phi)$, where $\omega = 2\pi\nu$ the ANGULAR VELOCITY and ν the frequency (the term “frequency” was introduced by GALILEO GALILEI [1564–1642]); as well as ϕ a PHASE difference depending on the boundary conditions. Vibrations are periodic motions with a periodicity or time constant that repeats the process for each cycle: $T = 1/\nu$, the total duration of a single oscillation (period). Vibration of an ELECTRIC CHARGE will provide a localized alternating current with associated alternating electric field and ensuing induced alternating MAGNETIC FIELD, providing an electromagnetic wave (PHOTON). Vibrations will have a base frequency and often higher harmonics superimposed. The harmonics will provide “COLOR” to a sound, or spectrum in the acoustic or optical analysis. Molecular vibrations are the main source for temperature, the mean kinetic energy; next to electronic vibrations as a result of temperature from a source of signal noise superimposed on the data, requiring filtering and smoothing to regain the clarity of the SIGNAL information. Undamped (“undamped”) or underdamped oscillations with a continuous force source will result in

RESONANCE phenomena that can lead to excessively large amplitudes. It is also referred to as oscillation (see [Figure V.28](#)).

Figure V.28 Vibration: (a) soil compactor based on tempering by combustion engine and (b) weight-loss vibration belt.

Villard, Paul Ulrich (1860–1934)

[general] Chemist from France who discovered gamma RADIATION in 1903. The studies of Villard on radium involved a PHOTOGRAPHIC PLATE that was sealed by a sheath of lead (known to stop the already discovered alpha-particles), but still yielded exposure, which was shown to consist of two types of radiation, one being beta rays (electron radiation, also known at the time) and a new unknown type of radiation. ERNEST RUTHERFORD (1871–1937) proposed the name gamma rays since they were more penetrating than alpha- or beta rays (named by Rutherford in 1899). Villard made the introduction of quantifying radiation exposure, later quantified by the unit Röntgen, after the elementary work performed by WILHELM CONRAD RÖNTGEN (1845–1923). These exposure QUANTIFICATION efforts still determines the current field of dosimetry in both medical applications and nuclear power plants (see [Figure V.29](#)).

Figure V.29 Paul Ulrich Villard (1860–1934).

Viscoelastic

[biomedical, fluid dynamics, mechanics, solid-state] Non-Newtonian behavior that has both viscous and elastic characteristics under deformation. Viscoelastic media have time-dependent strain, whereas a viscous medium has a linear relationship for strain under flow and deformation conditions; that is, exposure to stress. A viscoelastic medium has a dependence to shear rate with respect to the equation of motion. Examples of viscoelastic behavior are pseudoplastic and dilatant media. The equation of motion for fluids is generally defined by the Navier–Stokes equation for the velocity of motion $\vec{v}$ in a liquid with density ρ under applied forces $\vec{F}$ and pressure P as a function of time (t), which will integrate compensation for elastic dampening: $\rho((\partial\vec{v}/\partial t) + (\vec{v} \cdot \nabla)\vec{v}) = \rho\vec{F} - \nabla \cdot P + \eta_{\text{visc}} \nabla^2 \vec{v} + (\eta_{\text{bulk}} + (\eta_{\text{visc}}/3)) \nabla(\nabla \cdot \vec{v})$, where $\eta_{\text{visc}} = (5/16\sqrt{\pi})(\sqrt{(k_b T)/\sigma_r^2 \Omega_c^{2,2}})$ defines the viscosity ($k_b = 1.3806488 \times 10^{-23} \text{ m}^2 \text{ kg/s}^2 \text{ K}$ the Boltzmann constant, temperature T , σ_r molecular diameter, $\Omega_c^{2,2} = n_i n_j \int_{-\infty}^{\infty} \int_{4\pi} \{\phi_i(v^{*i})\phi_j(v^{*j}) - \phi_i(v^*)\phi_j(v^{**})\} \chi \sigma_R d\Omega d^3 v$ the Fokker–Planck collision integral, a special case of the Boltzmann collision integral ($\sigma_R = 1/4(Z_i Z_j / 4\pi \epsilon_0 m)^2 (1/\chi^2 \sin^4(\varpi/2))$ the RUTHERFORD CROSS SECTION; $m = m_i m_j / (m_i + m_j)$ the average mass for a two-component medium, Z_n the respective charges, $\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{Nm}^2$ the permittivity of free space, χ the SCALAR location within the vector potential, ϖ the ANGLE of impact, and $\phi_n(v^{**})$ the respective intermolecular potential for the interdependent constituents), η_{bulk} the bulk viscosity and the KINEMATIC VISCOSITY associated with the flow: $\eta_{\text{kin}} = \eta_{\text{visc}}/\rho$. The viscosity η_{kin} is linked to the material STRESS ($\sigma_s(t)$) and STRAIN ($\epsilon_s(t)$) as $\sigma_s(t) = \eta_{\text{kin}}(d\epsilon_s(t)/dt)$. The elastic compensations are introduced by the Volterra equations linking stress and strain as $\epsilon_s(t) = (\sigma_s/E_{Y,\text{creep}}) + \int_0^t K(t-t')[\partial\sigma_s(t')/\partial t']dt'$, where $K(t)$ is a CREEP function; $\sigma_s(t) = E_{Y,\text{relax}}\epsilon_s(t) + \int_0^t R(t-t')[\partial\epsilon_s(t')/\partial t']dt'$, $R(t)$ a relaxation function, E_Y a elastic modulus for creep and relaxation (*also see DAMPER*). For a Maxwell damper the stress–strain relationship can be written as $d\epsilon_{\text{tot}}(t)/dt = \sigma_s(t)/\eta_{\text{kin}} + (1/E_Y)[d\sigma_s(t)/dt]$. Alternatively, for the Kelvin–Voigt model the stress–strain relationship can be written as $\sigma_s(t) = E_Y\epsilon_s(t) + \eta_{\text{kin}}[d\epsilon_s(t)/dt]$. More complex models are available, combining serial and parallel elastic arrangement of the first two models, for instance, the Maxwell–Wiechert (also known as the generalized Maxwell model, after JAMES MAXWELL [1831–1879], respectively with contributions by Emil Wiechert [1861–1928]) approach. An extreme example of viscoelastic behavior is for chewing gum. BLOOD behaves as a Newtonian liquid only for high shear rate (greater than 100 s^{-1}) and for large vessel diameters (see [Figure V.30](#)).

Figure V.30 Diagram representing the viscoelastic behavior for a medium.

Viscoplastic

[fluid dynamics, general, mechanics] Decomposition of the strain rate into an elastic and a plastic component; application of elastic stress–strain applied to the strain rate; the use of plastic flow potential and compliant with the plastic flow rule. The plastic flow rule defines the conditions of flow under multiaxial loads, with additional boundary condition confinement provided by the evolution of the state variables with respect to PLASTIC STRAIN and RESISTANCE of the state variables to flow (analogous to yield stress). The strain rate decomposition is formulated by separation of the rate of STRAIN ($\epsilon_s(t)$) over time in elastic (e) and plastic (p) components: $(d/dt)\epsilon_s^{ij}(t) = (d/dt)\epsilon_{s,e}^{ij}(t) + (d/dt)\epsilon_{s,p}^{ij}(t)$, note $\epsilon_s^{ij}(t) = 1/2((\partial v_i/\partial x_j) + (\partial v_j/\partial x_i))$, with v_n the velocity of flow in the respective directions. This provides for the elastic strain rate: $(d/dt)\epsilon_{s,e}^{ij}(t) = E_{Yijkl}^*(d/dt)\sigma_s^{kl}(t) = [(1 + \nu_{\text{Poisson}})/E_Y](d/dt)\sigma_s^{ij}(t) - (\nu_{\text{Poisson}}/E_Y)(d/dt)\sigma_s^{kk}(t)\delta_{ij} + \alpha(dT/dt)\delta_{ij}$, where E_{Yijkl}^* is referred to as the Elastic COMPLIANCE tensor (Note: inverse to the generalized elastic modulus), E_Y is the Young's modulus, $\nu_{\text{Poisson}} = -(\epsilon_{\infty}/\epsilon_z) = -(\epsilon_{\text{transverse}}/\epsilon_{\text{logitudinal}})$ the Poisson ratio where ϵ_i is the strain in direction i , δ_{ij} the Kronecker delta, α_m a material property, and T the temperature (also see CREEP) (see Figure V.31).

Figure V.31 Diagram representing the viscoplastic behavior for a medium.

Viscosity

[fluid dynamics, general, mechanics] The relation in torque between a rotating object and a stationary object separated by a LIQUID.

Viscosity (η)

[atomic, biomedical, computational, fluid dynamics, mechanics, nuclear, solid-state] Apparent RESISTANCE a fluid applies to a body in MOTION, and even itself (equating to flow resistance), measured as a standard by dropping a sphere in a FLUID and measuring the rate of decent, expressed as $\eta = [2(\rho_{\text{sphere}} - \rho_{\text{liquid}})gR^2]/9v$, where ρ the density of the sphere or LIQUID respectively, g the GRAVITATIONAL ACCELERATION, R radius of the sphere, and v velocity of the sphere dropping through the liquid (see also DYNAMIC VISCOSITY OR COEFFICIENT OF VISCOSITY). Proportionality constant connecting the SHEAR STRESS (τ_s) between two plates in linear parallel movement with respect to each other and the speed of respective motion $\tau_s = F/A = \eta(U/h)$, where A is the

area of the contact surface between the two planes, b the separation DISTANCE between the planes, F the force applied to move one of the plates, and U the constant velocity of the MOTION. Another way of describing the viscosity of flow is in a tube where a column of flow experiences the resistance from the neighboring shell layer as a FRICTION force (F_f) expressed as a function of radius (r): $F_f(r) = \eta 2\pi r L (dv/dr)$, where L the characteristic length over which the pressure drop is measured, dv/dr the radial velocity gradient, for a laminar Newtonian flow the flow velocity will be a quadratic function with respect to radius, forming a parabolic velocity pattern with the maximum flow velocity in the center of the tube. Units centiPoise, dimensions: ML^2T^{-1} (also see NEWTONIAN FLUID, SHEAR THICKENING, and SHEAR THINNING) (see Figure V.32).

Figure V.32 Impact of the particulate concentration on the viscosity.

Viscosity, apparent

[general] See APPARENT VISCOSITY.

Viscosity, dynamic (η_{dyn})

[atomic, biomedical, computational, fluid dynamics, mechanics, nuclear, solid-state] Viscosity pertaining to the “mechanical flow resistance” of a FLUID with the neighboring shell layer as a FRICTION force (F_f) is expressed as a function of DISTANCE to the WALL of the solid (y): $F_f(r) = \eta_{dyn} A (dv/dy)$, where A is the area of interaction with, for instance, a flat wall, where $A = Lw$, L the characteristic length of interaction over a width w , also: dv/dr . the shear velocity gradient. Units centiPoise and dimensions: $ML^2 T^{-1}$. The wall can also be the surface of a sphere subject to flow, dropping through a LIQUID. The area of the sphere (only the area subject to flow) will replace the linear area mentioned earlier for the wall. The DYNAMIC VISCOSITY of gases can be determined by the absolute MANOMETER of Knudsen.

Viscosity, intrinsic

[fluid dynamics, general, nuclear] $[\eta] = \lim_{[c] \rightarrow 0} (\eta_{reduced})$, where $[c]$ is the SOLVENT concentration and $\eta_{reduced}$ the REDUCED VISCOSITY.

Viscosity, kinematic

[fluid dynamics] The standard viscosity multiplied by the GRAVITATIONAL ACCELERATION (g) and divided by the DENSITY (ρ) of the FLUID: $\eta_K = \eta(g/\rho)$, units St , dimensions: L^2T^{-1} . One specific example of KINEMATIC VISCOSITY applies to MOTOR OIL. To insure uniformity, the Society of Automotive Engineers (SAE) has designed specific tests to measure the flow rate of oil. The OIL grades are designated by a “weight” or viscosity grade, for instance, referred to as an SAE number. The SAE number is defined by a process that measures the time it takes for a predetermined quantity of oil to seep through an opening in a canister with a fixed diameter performed at a standard temperature. The temperature used for grading the viscosity of motor oil is generally $100^\circ C$. This temperature has been chosen to resemble the operating temperature for the average automobile engines. The higher the “weight” number in the SAE rating system, the thicker the oil, with respective slower flow; this refers to a single weight oil. In order to compensate for the changing temperature and LOAD conditions multiviscosity lubricants have been introduced. Multiweight lubricants are created by adding what is known as viscosity improver (VI) additives to oil, which makes the oils remain thicker at higher temperatures. Multiweight oils is designed to remain relatively constant in viscosity over a broad range of temperatures. The SAE classification for multigrade oils is described by two viscosity grades; for example, 10W-30, a common multigrade oil used in modern engines. Older engines were prescribed thicker oils such as 20W-50. The first number designates the viscosity at low temperature (“10W”), while the second number (“30”) represents the viscosity at $100^\circ C$. The “W” refers to cold weather use, and is derived from Winter. The viscosity rating scale for lubricants has been standardized by the American Petroleum Institute (API). The oil specifications from the ENGINE manufacturer will best suit all of the LUBRICATION requirements, over the lifetime of the engine. The actual MEASUREMENT temperature used to evaluate the performance (e.g., “cold start”) and define the grade of oil depends on the W-grade. For example, an oil with grade SAE 5W must be evaluated at $-35^\circ C$, while an SAE 10W grade oil must meet the shear rate viscosities ranges defined by the SAE J300 standards at $-30^\circ C$ (see Figure V.33).

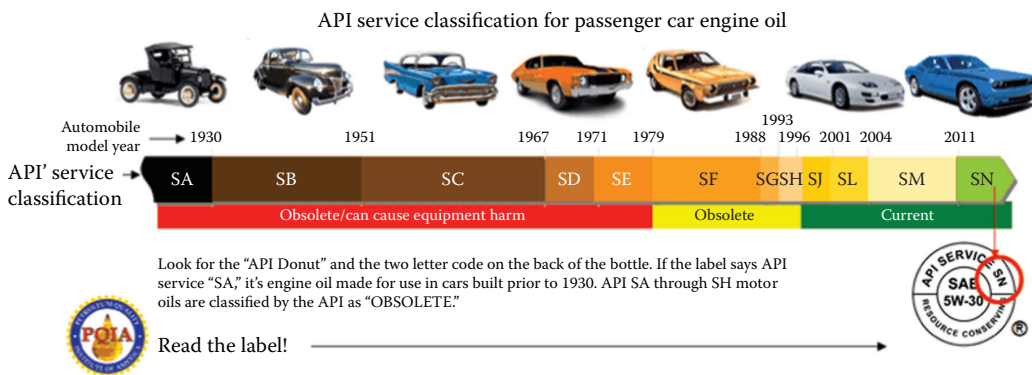

Figure V.33 Kinematic viscosity.

Viscosity, reduced

[fluid dynamics, general, nuclear] $\eta_{\text{reduced}} = \eta_{\text{specific}}/[c]$, where $[c]$ is the colloid concentration and η_{specific} the SPECIFIC VISCOSITY.

Viscosity, relative

[fluid dynamics, general, nuclear] $\eta_r = \eta_{\text{suspension}} / \eta_0$, where $\eta_{\text{suspension}}$ is the colloid viscosity and η_0 the viscosity of the SOLVENT.

Viscosity, specific

[fluid dynamics, general, nuclear] $\eta_{\text{specific}} = (\eta_{\text{suspension}} - \eta_0) / \eta_0$, where $\eta_{\text{suspension}}$ is the colloid viscosity and η_0 the viscosity of the SOLVENT.

Viscosity, static

[fluid dynamics, mechanics] Friction between two plates, one plate is moving with respect to the other plate, creating a force with respect to the stationary plate. Units $\text{centiPoise} \times \text{gram} \times \text{m}^{-3} = \nu$, dimensions: $M^5 L^2 T^{-1}$.

Viscosity, structural

[fluid dynamics] $\eta = \eta_0 \kappa_{\text{visc}}^{n-1}$ where η_0 is a material constant or baseline viscosity (Newtonian), $\kappa_{\text{visc}} = v(r, t) / b$ is the shear velocity with $v(r, t)$ the flow velocity of a COUETTE FLOW and b the DISTANCE between the walls (e.g., thickness of the viscous layer), and n is an indicator for the type of viscous behavior, with $n = 1$ for Newtonian, $n < 1$ for pseudoplastic (SHEAR-THINNING FLUID) and $n > 1$ for dilatant (SHEAR-THICKENING FLUID), as introduced by Ostwald and De Waele (1924) (see Figure V.34).

Typical response of materials with various viscosity structures
to a step change in shear rate

Figure V.34 Diagram illustrating the concept of structural viscosity.

Viscosity index

[fluid dynamics] See VISCOSITY.

Viscosity meter

[fluid dynamics, general] The viscosity of a flowing liquid can be determined from the flow: Q [m^3/s] as $Q = [\pi(P_2 - P_1)r^4] / 8\eta L$, where η is the VISCOSITY, L the length of the flow segment separating point 1 and 2 with pressures: P_i at the respective cross sections, and r the radius of the tube used to measure the flow. The viscosity is primarily determined by determining the time it takes for a fixed volume to pass through a segment of uniform tube.

Viscosity model

[biomedical, fluid dynamics] In flow DYNAMICS, the following FLUID characteristics can be defined: Newtonian: $\tau_s = \eta \dot{\gamma}$. Alternatively, for NON-NEWTONIAN FLUIDS—expressing the viscosity as a power function: $\eta = C \dot{\gamma}^{n'-1}$. The non-Newtonian behavior can be described for many different models: Pseudoplastic: $\tau_s = K \dot{\gamma}^n$ power function: ($n < 1$) $\{n' < 1\}$; Dilatant: $\tau = K \dot{\gamma}^n$ ($n > 1$) $\{n' > 1\}$; Bingham: $\tau_s = \tau_y + \eta \dot{\gamma}$; Casson: $\tau_s^{1/2} = \tau_0^{1/2} + \eta_c^{1/2} \dot{\gamma}^{1/2}$; Cross: the material stress σ_s is split for viscosity under low shear rate ($\dot{\gamma}$) η_0 , or viscosity under high shear rate η_∞ as a power function (power n) as $\sigma_s = \dot{\gamma} \left(\eta_\infty + (\eta_0 - \eta_\infty) / (1 + m_{Cr} \dot{\gamma}^n) \right)$, m_{Cr} a model constant; Herschel–Bulkley: $\tau = \tau_y + K \dot{\gamma}^n$; where τ_s is the shear stress, $\dot{\gamma}$ the shear rate, η the APPARENT VISCOSITY, K the consistency index for the medium, n is what may be best described as the “flow behavior index,” the subscript: c indicates a critical value or threshold (see Figure V.35).

Figure V.35 Viscous models.

Viscosity of deformable spherical particles (η_{sph})

[fluid dynamics, general, nuclear] Spherical objects in SOLUTION that are forced into a spherical configuration by SURFACE TENSION will be compliant in contrast to rigid particles. The viscosity is defined by the FLUID viscosity of the droplets $\bar{\eta}$ and the material constant baseline Newtonian viscosity η_0 as $\eta_{sph} = \eta_0 \left(1 + c_1 \left[(1 + (5/2)(\bar{\eta}/\eta_0)) / (1 + (\bar{\eta}/\eta_0)) \right] \right)$, which also shows that for rigid droplets the fluid viscosity of the droplet becomes infinite ($\bar{\eta} \rightarrow \infty$) and the INTRINSIC VISCOSITY becomes $5/2$.

Viscous lubrication

[fluid dynamics] Flow BOUNDARY LAYER formed in close contact between a BUBBLE, red BLOOD CELL or solid object, and the WALL of the FLUID container.

Vision

[biomedical, chemical, optics] Conversion of electromagnetic RADIATION into electrical impulses by chemical conversion in the EYE. The eye is the anatomical component responsible for the electrochemical mechanism of vision. The electrical impulses are transmitted to the brain by neurons, which in turn generates a PERCEPTION with associated interpretation by the observer. In early Greek times the concept of EXTRAMISSIION, postulated by EUCLID (c. 325–270 BC), PTOLEMY (90–168 AD), and PLATO (427–347 BC) in various versions, was used to describe vision. It was proposed that the eye supposedly emits radiation, which is returned by objects in its path back to the eye to be recognized as vision. Extramission, however, does not account for not being able to see when no external LIGHT is provided. Two kinds of vision are recognized based on the biological and anatomical features next to the chemical processes involved. The two types of vision are intensity (grayscale) and COLOR vision. Intensity vision is achieved by the anatomical feature of the RODS, whereas the color vision is achieved through the CONES. Human vision and vision of specific species can be very different due to the specific requirements in the daily routine. For instance, birds of prey have a segmented vision which relies on two components of the RETINA to act as low and high RESOLUTION vision as described under ABBE CONDITION. Vision in the mammalian and reptilian eye is primarily controlled by accommodation of the CRYSTALLINE LENS. In insects the vision has an entirely different compound structure, constructed of a multitude of fixed APERTURES arranged in a honeycomb structure, providing a similar structure as multiple CAMERA-OBSCURA projections (*also see* SCOTOPIC and PHOTOPIC VISION).

- Trichromat: sees using all three colors (red/green/blue)
- Color vision problems
- Anomalous trichromat: reception of one pigment is reduced or misaligned (anomalous)
- Dichromat: only two of the three visual pigments exist—red, green, or blue is missing
- Protanomaly: reduced red sensitivity in an anomalous trichromat
- Deuteranomaly: reduced green sensitivity in an anomalous trichromat
- Protanopia: unable to receive first visual pigment (RED)

- Deuteranopia: unable to receive second visual pigment (green)
- Tritanopia: unable to receive third visual pigment (blue) (see Figure V.36)

Figure V.36 Vision. (From Dreyfuss, H., *The Measure of Man; Human Factors in Design*, John Wiley & Sons, New York, 1959.)

Visual acuity

[biomedical, optics] The ability to see with high precision. One reference is with respect to the expression 20/20 vision for visual acuity. The statement 20/20 vision represents the ability to distinguish objects at a DISTANCE of 20 ft, set as the standard in the United States. Any deviations are expressed with different numbers; for instance, 20/100 vision reflect the fact that this person can see at 20 ft distance what a person with standard VISION can see at 100 ft distance. The statement 20/20 vision is no indication of perfect vision, just an indication of clarity; while vision clarity as high as 20/10 is possible for a normal person. An international standard for visual acuity is obtained with a reading chart, the Snellen chart (see [Figure V.37](#)).

Figure V.37 Vision acuity scale. As set as standards by the International Council on Ophthalmology in 1984.

Vital capacity (VC)

[biomedical, fluid dynamics] The maximum potentially exhaled volume of gas from the lungs after the lungs are filled to TOTAL LUNG CAPACITY (TLC) during inspiration. Vital capacity and other TIDAL BREATHING parameter can be measured with a spirometer (*see* RESPIRATION).

Vitreous humor

[biomedical, optics] Gel-like substance between the backside of the CRYSTALLINE LENS and the RETINA in the HUMAN EYE. The vitreous humor has an index of refraction of $n_{\text{vitreous humor}} = 1.337$, keeping in mind that water has $n_{\text{H}_2\text{O}} = 1.331$, and AIR $n_{\text{air}} = 1.0001$. The vitreous humor also has a designated canal within the gel

that leads a confined path with a lower index of refraction directly to the FOVEA, the area of the retina with the highest density of RODS and CONES for high-resolution COLOR and brightness VISION (see [Figure V.38](#)).

Figure V.38 Vitreous humor.

Voice

[biomedical, general] SOUND generated by the vocal cord of humans. Several factors determine the frequency content of the spoken sounds, specifically the difference between male and female voice spectrum is generally recognized, but is not defined absolute. A adult male bass voice can have an approximate frequency range from 65 to 400 Hz (starting at a “low-C” note), where an alto voice roughly ranges from 200 to 70 Hz, and a soprano spans in the range 261 to 1047 Hz ranging to a “high-C;” respectively for a female 261 to 1280 Hz. The adult female voice for general speech ranges generally from 165 to 255 Hz, while a female scream can reach 3000 Hz; whereas the male conversational voice is on average in the spectrum 85 to 155 Hz. Children may reach higher tones, up to 3500 Hz (see [Figure V.39](#)).

Figure V.39 Voice, as generated by the larynx, representative average spectral profile for man, woman, and child. (Courtesy of DPA Microphones, Alleroed, Denmark.)

Volcano

[acoustic, astrophysics, chemistry, electromagnetism, fluid dynamics, geophysics, mechanics, solid-state, thermodynamics] The study of the physical phenomena at the planet's surface due to eruption from the magma contained in the ASTHENOSPHERE when penetrating the lithospheric plates (see [Figure V.40](#)).

Figure V.40 Volcano; the erupting magma is hot enough to emit visible light under the Planck black-body radiation.

Volta, Alessandro Giuseppe Antonio Anastasio Gerolamo Umberto, Count (1745–1827)

[biomedical, electronics, energy, general] Italian scientist with a focus on PHYSICS, whose work was instrumental in the development of the BATTERY as well as the understanding of capacitance. Alessandro Volta was awarded the title Count by the Emperor Napoléon Bonaparte (1769–1821) in 1801 for his scientific contributions. Volta and his contemporary LUIGI GALVANI (1737–1789) had a close collaboration that formed the basis of several electrostatic and electrical current discoveries. Galvani was the inspiration to the formulation (1780) of the battery concept by Conte Alessandro Volta, as revealed in 1800 (see [Figure V.41](#)).

Figure V.41 Count Alessandro Giuseppe Antonio Anastasio Gerolamo Umberto Volta (1745–1827).

Voltage (V)

[electronics, general] Parameter used to define the electrical potential. Voltage is the electrical potential ENERGY per unit charge. Voltage difference between two POINT CHARGES is the electric field between the two locations multiplied by the separation of the two charges, expressed in units volt (V). The voltage between point A and point B is also equal to the work performed on an ELECTRIC CHARGE to move it from point A to point B, per unit charge (V_{AB}).

Voltaic pile

[general] Stack of alternating media designed by ALESSANDRA VOLTA (1745–1827) that provides a potential difference between the opposite ends of the stack. The pile was created out of disks made of zinc cardboard, silver and cardboard (i.e., cells), repeated (see [Figure V.42](#)).

Figure V.42 Voltaic pile.

Voltaire

[general] Pseudonym of the writer and scientific activist from France: FRANÇOIS-MARIE D'AROUET (1694–1778). Voltaire used science to arouse the public awareness and to guard people against the unfounded tales of natural phenomena, specifically his fight against superstition. Although not a scientist himself, he used science to raise the standards of analytical thinking (see [Figure V.43](#)).

Figure V.43 Voltaire; François-Marie d'Arouet (1694–1778).

Voltmeter

[electromagnetism, general] Galvanometer in series with a resistor with the primary purpose of measuring the electrical potential between two points. The RESISTANCE is chosen to provide the idealized conditions of zero current, in order to prevent influencing the charge storage on the device being measured for voltage difference. Generally, the voltmeter is integrated in a multifunctional device that can measure current, voltage, and resistance called a multimeter (see [Figure V.44](#)).

Figure V.44 Voltmeter: (a) analog and (b) digital.

Volume (V)

[general] Parameter with the primary meaning as the indication of three-dimensional containment. Reservoir with specific size, expressed in liter, m^3 in SI UNITS, or in gallon or FLUID ounces in the obsolete English (Imperial) unit system. Alternatively, the volume of SOUND is an indication of the AMPLITUDE of the acoustic WAVE, used for QUANTIFICATION of listening to audio (see [Figure V.45](#)).

Figure V.45 Volume measurement with calibrated flasks and beakers.

Volume charge density (ρ_e)

[general] The total charge ($Q = \sum q$) in a volume of medium divided by the respective volume (V): $\rho_e = Q/V$. In contrast, the charge can be spread over the surface of a medium, specifically a plate, but also for a CONDUCTOR all charge will be concentrated on the surface. The charge spread over a surface is expressed by surface density, respectively: σ_e . On a wire the charge density will be a line-charge density (one-dimensional), expressed as λ_e .

Von Fraunhofer, Joseph (1787–1826)

[optics] Scientist and physicist from the Prussian Empire (Germany) that was influential in optical discoveries. Joseph was born into a family of glassmakers, which led him to work on LENS development, making very accurate and proficient achromatic lenses. Based on his interests in OPTICS, Von Fraunhofer discovered the ATOMIC EMISSION SPECTRUM for the SUN in 1814, separating out more than 574 lines. Additional work by Fraunhofer was in the experimental and theoretical work on the diffraction from multiple thin slits, using closely spaced wires; DIFFRACTION GRATING. Josef von Fraunhofer is frequently referred to as “Fraunhofer.” (see [Figure V.46](#))

Figure V.46 Joseph von Fraunhofer (1787–1826).

Von Guericke, Otto (1602–1682)

[astronomy, general] Scientist, physicist, and engineer from Germany (Prussian Empire). The first static electricity charge generator was developed by Otto von Guericke in 1650. Additional work by Von Guericke was in. The VACUUM work by Von Guericke was performed on a system referred to as the Magdeburg hemispheres, two copper hemispheres with flanges attached on respective tips of the dome, and an outlet VALVE to provide the means to evacuate the dome. The flanges gave the hold to apply tensile force on both hemispheres. Von Guericke provided the foundation for modern METEOROLOGY, and worked on

ELECTROSTATICS as well. His electrostatic efforts provided one of the first documented devices to generate a substantial electrostatic charge (see [Figure V.47](#)).

Figure V.47 Otto Von Guericke (1602–1682), engraving after a portrait by Anselm van Hulle.

Von Helmholtz, Hermann Ludwig Ferdinand (1821–1894)

[biomedical, electrodynamics, energy, mathematics, thermodynamics] Physicist and mathematician from the Prussian Empire (Germany) (see **HELMHOLTZ, HERMANN LUDWIG FERDINAND VON**) (see [Figure V.48](#)).

Figure V.48 Hermann Ludwig Ferdinand von Helmholtz (1821–1894).

Von Kármán, Tódor (Theodore) (1881–1963)

[astrophysics, fluid dynamics] Physicist and mathematician from Hungary. Theodore von Kármán contributed to the theoretical description of vortices and TURBULENCE, next to his work in aerospace ENGINEERING. Von Kármán designed one of the first functioning helicopters in the early 1920s. Later in his career Von Kármán provided guidance to the design and development of rockets, guided missiles, and PROPULSION jets for fighter planes. Von Kármán's work in FLUID DYNAMICS has made significant contributions to the

understanding of boundary layers and turbulence phenomena; specifically the “KÁRMÁN VORTEX STREET” description (see [Figure V.49](#)).

Figure V.49 Theodore von Kármán (1881–1963). (Courtesy of United States Army, United States Army Scientific Advisory Board, Washington, DC, USA.)

Von Kármán vortex street

[fluid dynamics, general] See **KÁRMÁN EDDY CURRENT VORTEX STREET**. It is also known as “Kármán vortex street.” (see [Figure V.50](#))

Figure V.50 Satellite image of von Kármán vortex street in the cloud cover, downwind from Guadalupe Island. (The Guadalupe island is located off the west coast of Baja, California). (Courtesy of University of Wisconsin, Madison, WI.)

Von Kleist, Ewald Jurgens (1700–1748)

[energy, general] Administrative clerk and engineer from Prussia (former greater German Empire) who discovered the mechanism of storing charge in a jar with LIQUID, the LEYDEN JAR. The charge storage was performed during his studies in Leiden (old Dutch vernacular: “Leyden”), hence the name (see [Figure V.51](#)).

Figure V.51 Ewald Jurgens von Kleist (1700–1748).

Von Laue, Max Theodor Felix (1879–1960)

[computational, electromagnetism, nuclear] Physicist from Germany. Max von Laue received the Nobel Prize in Physics for his X-RAY diffraction work (performed in 1912), and the ensuing understanding of crystal and LATTICE structure of atomic and molecular configurations. The lattice structure theory was supported by contributions from Sir WILLIAM LAWRENCE BRAGG (1890–1971) in 1913. Von Laue worked on crystallography, OPTICS, relativity, SUPERCONDUCTIVITY, and QUANTUM THEORY (see [Figure V.52](#)).

Figure V.52 Max Theodor Felix von Laue (1879–1960). (Courtesy of German Federal Archive [Deutsches Bundesarchiv], Koblenz, Germany.)

Von Laue's method

[computational, nuclear] Mathematical method based on the work of MAX THEODOR FELIX VON LAUE (1879–1960) describing electron and NEUTRON diffraction on atomic level, revealing the atomic and LATTICE structure of crystals and solid-state configurations. The Laue method provides a lattice description based on observations. The Laue method is based on the Miller index for lattice planes, using the lattice vector ($\vec{b}$), describing the plane spacing and orientation for the various lattice p -lanes, and the correlation with the respective LATTICE SPACING distance d_i , defined as $d_i = 1/|\vec{b}|$. The refraction of X-rays in a crystal is described by the Laue equation (based on the Bragg's law), in one dimension as $(AB - CD) = a \{ \cos(\alpha_n - \cos \alpha_0) \} = n_x \lambda$, where λ is the wavelength of the probing RADIATION. The diffraction pattern of the crystal resulting from exposure to a collimated narrow the X-RAY beam produced a pattern of spots which were supposedly correlated to the internal symmetry of the crystal; which was experimentally and theoretically confirmed (see Figure V.53).

Figure V.53 Von Laue method diagram of action.

Von Leibniz, Gottfried Wilhelm

[general] See LEIBNIZ, GOTTFRIED WILHELM VON.

Von Lenard, Philipp Eduard Anton (Lénárd Fülöp Philipp Eduard Anton von Lenard) (1862–1947)

[atomic, nuclear] Scientist from Slovakia/Austria-Hungary, now Germany. Von Lenard's work revealed important details about the "cathode ray." Other work was with respect to the MECHANICS, that is, oscillations, of precipitated water droplets. His interests in PHOSPHORESCENCE and luminescence led him to artificially

generate RADIATION. Lenard was able to generate LUMINESCENCE using a CATHODE ray in a VACUUM tube lined with aluminum, his discovery of the “Lenard window.” (see [Figure V.54](#))

Figure V.54 Philipp Eduard Anton von Lenard (1862–1947), approximately in 1900. (Courtesy of VendégVáró archív, <http://lexikon.vendegvaro.utazom.com/lenard-fulop-philipp-e-a-von-lenard>.)

Von Mayer, Julius Robert (1814–1878)

[general, thermodynamics] Physicist, physician, and engineer from Prussia (Germany), one of the founding fathers of THERMODYNAMICS. Von Mayer described the law of the CONSERVATION OF ENERGY (the FIRST LAW OF THERMODYNAMICS), and formulated the vital chemical process as the primary source of ENERGY for any living creature as OXIDATION, both in 1842. Von Mayer also proposed the rudimentary concept of PHOTOSYNTHESIS. His conservation of energy statement was largely overlooked and is mainly attributed to JAMES JOULE (1818–1889) who made his proclamation 1 year after Julius von Mayer (see [Figure V.55](#)).

Figure V.55 Julius Robert von Mayer (1814–1878).

Vortex

[computational, fluid dynamics, mechanics, thermodynamics] Conglomeration of particles involved in rotational motion, primarily relating to fluids. A detailed theoretical description of the velocity DISPERSION

in rotational MOTION of a LIQUID was first provided by HERMAN VON HELMHOLTZ (1821–1894). Due to the complex three-dimensional velocity profile Helmholtz-introduced velocity profiles with respect to the axis of rotation (i.e., vortex line) as the following directional gradient components of the vorticity:

$\xi_V = (\partial w / \partial y) - (\partial v / \partial z)$; $\eta_V = (\partial u / \partial z) - (\partial w / \partial x)$; $\zeta_V = (\partial v / \partial x) - (\partial u / \partial y)$, in CARTESIAN COORDINATES

$u = -(\partial \phi / \partial x)$ is the velocity in the x -direction, $v = -(\partial \phi / \partial y)$ is the velocity in the y -direction, and

$w = -(\partial \phi / \partial z)$ is the velocity in the z -direction, with ϕ is the VELOCITY POTENTIAL. The vortex line is defined

as $(\partial x / \partial \xi_V) = (\partial y / \partial \eta_V) = (\partial z / \partial \zeta_V)$. In general, the rotation motion of a FLUID can be derived by solving:

$(P/\rho) + (1/2)q_*^2 + E_V = (\partial \phi / \partial t) + F_V(t)$, where P is the local pressure on a streamline, ρ the fluid density,

the resultant velocity in the vortex is defined by $q_* = \sqrt{u^2 + v^2 + w^2}$, $E_V = -\int P d(1/\rho)$ is the work performed

by a unit of fluid mass in response to the external pressure, and $F_V(t)$ is a time function (t) describing the

rotational characteristics. More accurately the vector potential with respect to two moving particles A and B

along the streamline can be derived from: $\left[\int_A^B ((P/\rho) + \Omega - (1/2)q_*^2) \right] = -(D/Dt) \int_A^B (u dx + v dy + w dz)$, where

Ω is the force potential resulting from all external forces involved in the movement of the particles in the

vortex with potential ENERGY: $PE = \iiint \Omega \rho dx dy dz$. Since the velocity potential is tied to the kinetic energy

the velocity potential can be linked to the force potential as $(P/\rho) = (\partial \phi / \partial t) - \Omega - (1/2)q_*^2 + F_V(t)$. The

velocity field distribution: $\vec{v}(\vec{r}_p)$ (i.e., vector potential) in the vortex can be derived based on the VORTICITY

$(\vec{\omega})$ as $\vec{v}(\vec{r}_p) = 1/4\pi \int_V (\vec{\omega}(\vec{Q}, t) \times \vec{r}_{pQ}) / r_{pQ}^3 dV_Q$, where $\vec{P}$ and $\vec{Q}$ are positions on the axis or rotation and at the

revolution trajectory in the plane of interest and $\vec{r}_{pQ} = \vec{r}_p - \vec{r}_Q$, respectively. Using the vorticity $(\vec{\omega}(\vec{r}, t))$, the

linear impulse (I) and angular impulse ($\mathbb{A}$) of a vortex within a VOLUME (V) at location $\vec{r}$ can be defined as

follows: $I = (1/2)\rho \int_V \vec{r} \times \vec{\omega}(\vec{r}, t) dV$, and $\mathbb{A} = -(1/2)\rho \int_V \vec{r}^2 \vec{\omega}(\vec{r}, t) dV$, where ρ is the local density of the

INCOMPRESSIBLE FLUID with no viscosity (i.e., inviscid) (see Figure V.56).

Figure V.56 Vortex: (a) formation of vortex on wing tip and (b) vortex behind wing of plane landing. (Courtesy of NASA Langley Research Center, Hampton, VA.)

Vortex, Kármán

[fluid dynamics] See **KÁRMÁN EDDY CURRENT VORTEX STREET**.

Vortex shedding

[computational, fluid dynamics, mechanics, thermodynamics] During the flow around a bluff body a KÁRMÁN VORTEX street is formed which has a pattern of flow that detaches from different locations on the circumference of the body to form a VORTEX pattern in the WAKE of the body. This detachment (shedding) occurs at a characteristic frequency. The shedding frequency is characterized by flow conditions and geometry. For a cylindrical object with flow condition defined by a Keulegan–Carpenter number equal to or greater than 20 ($K_C \geq 20$; *Note*: in this range the REYNOLDS NUMBER is relatively constant), the vortex-shedding frequency can be defined. This range categorizes QUASI-STEADY-STATE shedding conditions. For $K_C < 20$ the flow has fractional vortex shedding which does not allow for a steady frequency pattern to develop. The vortex-shedding frequency for $K_C \geq 20$ can be defined as $v_V = \text{Sr}(U_o/D)$, where Sr is the STROUHAL NUMBER (accounting for the SURFACE ROUGHNESS of the cylindrical object, e.g., PIPE), U_o the instantaneous flow velocity, and D the diameter of the cylindrical object in the flow path. In the case of flow around a prolate spheroid the unsteady Navier–Stokes equation for incompressible flow at a function of TIME (t) will need to be solved: $\nabla \cdot u = 0$ and $(\partial u / \partial t) + u \cdot \nabla u = -\nabla P + (1/\text{Re}_\infty) \nabla^2 u$, where ∇ is the Laplace operator, u is the flow velocity, P the pressure, Re_∞ the Reynolds number based on the free-stream flow velocity u_∞ , and d the diameter of the sphere. This spheroid vortex shedding frequency SOLUTION can only be obtained by NUMERICAL analysis.

Vorticity ($\vec{\omega}$)

[fluid dynamics] The degree of “rotation” experienced in flow VELOCITY ($\vec{v}$) as a function of location ($\vec{r}$) and TIME (t) expressed as $\vec{\omega}(\vec{r}, t) = \nabla \times \vec{v}(\vec{r}, t)$, which is the “curl” of the velocity at a given place (i.e., vector operator performing the rotation in infinitesimal steps of a three-dimensional vector field; curl: operator defining the rotation of the vector in infinitesimal steps, hence describing the projection of the vector upon all possible lines passing through the location in the three-dimensional space). The vorticity defines the CIRCULATION density derived from the flow velocity vector field. For an inviscid FLUID the rate of change in time for the VORTEX is described as $[d\vec{\omega}(\vec{r}, t)/dt] = \vec{\omega}(\vec{r}, t) \cdot \nabla \vec{v}(\vec{r}, t) + \nabla \times \vec{F}$, where $\vec{F}$ is the externally applied force density.

Voxel

[computational, fluid dynamics, imaging] Three-dimensional configuration with unique and uniform parameters and characteristics. This is the three-dimensional equivalent of the two-dimensional PIXEL in IMAGE reconstruction. The voxel is an ELEMENT in finite element analysis, used in computer simulations (e.g., Monte Carlo, finite element), image reconstruction and geometric deconvolution of real-time events in well-defined compartments. The three-dimensional representation of PET, computed-tomography, ULTRASOUND and other imaging techniques uses voxels as the smallest unique geometric unit in the visualization rendering process (see [Figure V.57](#)).

Figure V.57 Voxel.

V(z) inversion

[acoustics, imaging] SIGNAL processing technique used in acoustic microscope that allows for the extraction of material properties based on the power of the signal as a function of the location (position: “z;” the focal position) of the collection LENS. The spectral profile of the power profile of the acoustic imaging provides the means to derive the Young’s modulus. The ν -curve is a graphical deduction from the power losses per phase in a vector analysis of the Rayleigh wave velocities. The ν -inversion extracts the material properties based on ν -curves and applying PERTURBATION THEORY to the representation.

Taylor & Francis

Taylor & Francis Group

<http://taylorandfrancis.com>

Wake

[fluid dynamics] Vortices where the BOUNDARY LAYER of a flow detaches from the fixed surface. This phenomenon is more pronounced when the flow separates around the back side of a symmetric body totally submerged, reducing it to a two-dimensional flow such as a symmetric round pillar or a stick sunken into a solid foundation. This process becomes increasingly noticeable with an ascending REYNOLDS NUMBER, separation at the 180° point starts in the approximate range $2 < Re < 30$, depending on the boundary conditions. When the Reynolds number comes in the range $10^2 < Re < 10^5$, separation occurs before the midway point of the bluff rounded object, mainly before the 80° angle on the curved surface of the rod, measured from the centerline with the rod. This detachment generates KÁRMÁN EDDY CURRENT vortices (see [Figure W.1](#)).

Figure W.1 Wake.

Walecka, John Dirk (1932–)

[nuclear, quantum] Nuclear physicist from the United States. Walecka is known for his work on QUANTUM THEORY, specifically for many particles. John Walecka led the electron accelerator research at CEBAF (Continuous Electron Beam Accelerator Facility in Newport News), Virginia (see [Figure W.2](#)).

Figure W.2 John Dirk Walecka (1932–). (Courtesy of Jefferson Lab, Newport News, VA; the U.S. Department of Energy's Thomas Jefferson National Accelerator Facility; U.S. Department of Energy; College of William and Mary, Williamsburg, VA.)

Wall

[biomedical, fluid dynamics, general, mechanics] Solid structure, mechanical separating structure, specifically with respect to objects or fluids in MOTION. The wall of a flow system determines the flow boundary conditions and flow-separation parameters. In biological context, a wall can have COMPLIANCE, such as the arterial wall, which stretches to accommodate the periodic in-flow with a high down-stream impedance (i.e., the vessel wall). The biological wall is different from many structural or industrial wall structures in the fact that it also provides a mechanism for osmotic DIFFUSION through the wall, well known as the diffusion of oxygen and carbon dioxide in the alveolar wall and the CAPILLARY wall of the lung organ structure. Generally walls are rigid and are designed mechanically to perform a specific function with thresholds for stability and durability. The wall of a confinement for a hydroelectric plant can burst when the security thresholds set as acceptable limits under design are exceeded. PIPE walls are generally made with metallic or POLYMER compounds, which can DECAY in strength over time and require frequent quality

control inspections to identify hairline cracks, which may propagate and generate conditions where the pipe may break. The process of crack propagation is an elaborate and complex procedure (see Figure W.3).

Figure W.3 (a) Wall, rigid drain pipe and compliant blood vessel (b) with an uneven surface structure.

Wall attachment phenomenon

[fluid dynamics] Fluid flow in close proximity to a **WALL** will form a **BOUNDARY LAYER** where the **FLUID** may attach to the wall and form a thin boundary layer in which there is no flow, that is, flow velocity is zero. The boundary layer can effectively generate the conditions to sustain the flow of the fluid with minimal friction (viscosity effects). Flow bordering a wall can result in detachment that results in turbulent pocket formation (the Coandă effect). Under Navier–Stokes dominated flow conditions, a boundary layer is formed with a thickness that is a function of the flow velocity (v) and the time constant (t') associated with the flow (respectively, periodic or continuous), defined as $\delta_b = \sqrt{vt'}$. At a low **REYNOLDS NUMBER** ($Re < 1$), the flow will not separate due to superior viscous behavior over inertial effects, maintaining a **LAMINAR FLOW** around an object. Certain sports ball designs use **SURFACE ROUGHNESS** to influence the boundary layer behavior and promote an early transition from a laminar to a turbulent flow. These ball games rely on operating in a Reynolds number range that is near the “minimum” of the “**DRAW COEFFICIENT**” ($C_d = F_d / (1/2)\rho v^2 A$, where F_d is the **FRICTION** of flow, the drag force, ρ density, and A the contact surface area) versus Reynolds number (Re) curve. Under these conditions, the drag will be lowest (*also see BOUNDARY LAYER*) (see Figure W.4).

Figure W.4 Wall attachment phenomenon.

Wall factor 1 ($K_2 = 2(d_{PV}/D_C)$)

[fluid dynamics] Ratio of the sphere diameter to the column diameter for a ball falling down a LIQUID column, where d_{PV} is the sphere diameter equivalent to the PARTICLE volume, and D_C column diameter (see [Figure W.5](#)).

Figure W.5 Outline of the concept of Wall factor.

Wall factor 2 ($K_3 = (d_{PV}/D_C)(Z/D_C)$)

[fluid dynamics] Ratio of the sphere diameter to the column diameter for a ball falling down a LIQUID column multiplied by the relative SURFACE ROUGHNESS expressed as the size of the sediment (the bed height Z) over the flow diameter, where d_{PV} is the sphere diameter equivalent with the PARTICLE volume, and D_C is column diameter.

Wallis, John (1616–1703)

[general] Mathematician from Great Britain, involved in the scientific analysis of collisions. Wallis has one of the first documented applications of conservation of momentum, published in 1663. John Wallis formulated a method to solve for spatial indivisibles by means of interpolation (see [Figure W.6](#)).

Figure W.6 John Wallis (1616–1703) painted by Sir Godfrey Kneller. (Courtesy of The Wallis Project, University of Oxford, UK.)

Wall-tracing method

[fluid dynamics] Mechanism for visualization in close proximity to the WALL of flow, either by tufts or release of dye or BUBBLES. The wall-tracing method yields insights into attachment and detachment of flow at the BOUNDARY LAYER, flow velocity direction, and transition layers. One of several mechanism available to visualize flow patterns. Other techniques available are smoke lines, BIREFRINGENCE, wall tufts, bubble, dye, surface powder, schlieren, and PARTICLE suspension (equal density to the FLUID). These methods can elucidate four concepts: (1) streamlines, (2) timelines, (3) pathlines, and (4) streaklines. Streamlines are indicators of the flow-velocity vector, tangent to the flow direction. Timelines provide an instantaneous snapshot of the flow pattern of the mechanism used for visualization. Pathlines follow individual particles over a specific time interval. Streaklines yield information about a range of identifying units for a locus (single point) in the flow over a specific interval of time. The flow visualization techniques can be classified based on the mechanism of action as optical (Schlieren, shadow, birefringence, etc.), marker (SOLUTE, bubble, etc.), or mechanical (tufts, surface release, etc.) (see [Figure W.7](#)).

Figure W.7 Wall-tracing method for fluid flow.

Walton, Ernest Thomas Sinton (1903–1995)

[atomic, nuclear] Scientist from Ireland, primarily known for his work on PARTICLE ACCELERATOR technology to enhance the efficacy of nuclear interactions (the Cockcroft–Walton accelerator). The work of Ernest Walton was different from the earlier efforts by ERNEST RUTHERFORD (1871–1937) using helium ions (ALPHA PARTICLES) and were based on PROTON interaction under an applied force resulting from an external electric field in 1932. Ernest Walton and the British physicist John Cockcroft (1897–1967) received in 1951 the Nobel Prize in Physics for their combined effort on the particle accelerator (see [Figure W.8](#)).

Figure W.8 Ernest Thomas Sinton Walton (1903–1995).

Water (H₂O)

[biomedical, chemical, fluid dynamics, general] CHEMICAL COMPOUND consisting of hydrogen and oxygen in a two to one ratio, joined by covalent bonds. The water molecule is shaped in the form of a V, but spread out at an ANGLE between the O–H bonds of approximately 104.5°. The “lob-sided” configuration provides the platform for the polarity of the water MOLECULE. Water is one of the most abundant substances on the EARTH, covering more than 70% of the earth’s surface area. Water is an essential medium to sustain biological life-forms, the HUMAN BODY for instance consists of approximately 59% of water. The constituents of water form one of the many options in the fuel-cell technology. Water forms the LIQUID phase of H₂O; alternatively ice is the solid phase and water VAPOR (steam) provides the GAS PHASE. Water forms the base for several scientific definitions of material properties. The SPECIFIC HEAT of water at standard pressure and temperature is $h_p = 1 \text{ cal/g}^\circ\text{C}$ (old units, but illustrating the historical value). The density of water under standard conditions is $\rho = 1 \text{ kg/L} = 1 \text{ g/cm}^3$. Note that water has the highest density at 4°C. The “acidity” of water has a PH of 7, on a scale ranging from 0 to 14; considered neutral. A pH lower than 7 indicates ACID (acidic) and a higher pH is “alkali” or base. Water has formed the foundation for the temperature scale in Celsius and Fahrenheit. On the CELSIUS SCALE, the FREEZING point yielding 0 (0°C), and the boiling point providing the landmark 100 (100°C) on the scale, as introduced by the Swedish scientist ANDERS CELSIUS (1701–1744) in 1742. The Celsius scale is the most widely used temperature scale, in comparison to the Fahrenheit scale devised by the Polish (Prussian) scientist GABRIEL DANIEL FAHRENHEIT (1686–1736) in 1724 based on the MELTING POINT of a mixture of ice, water, and ammonium chloride SALT (brine) at 0°F, versus the human body temperature (his wife’s oral temperature) as the second calibration point, providing 96°F at the time of the recordings (the Fahrenheit scale originally had a 12 base,

hence 96 as the body temperature, later adjusted for accuracy and on a decimal scale; currently the average human body temperature is set at 98.6°F). The Fahrenheit scale is primarily used only in the United States, whereas the rest of the world uses the Celsius scale for household and medical use. The Kelvin scale is technically the standard for temperature, as devised by the Scottish (British) scientist SIR WILLIAM THOMSON, LORD KELVIN (1824–1907) in 1854, which is not based on water (see [Figure W.9](#)).

Figure W.9 Water.

Water clock

[fluid dynamics] Next to the SUN dial, one of the oldest methods for measuring time. The water clock was first described based on historic finds dating back to the sixteenth century BC, whereas there are claims of Chinese water clocks as far back as 4000 BC. The Babylonian (city of Babylon; now part of Iraq [cultural and scientific center of Mesopotamia]), and later Greek, water clock was based on a set of bowls with fixed ORIFICE regulating the outflow rate (see [Figure W.10](#)).

Figure W.10 Modern day equivalent of the ancient water clock concept.

Water hammer

[fluid dynamics] Hydraulic shock produced when the flow of a liquid (GAS or fluid) is suddenly interrupted. The phenomenon was first described by Lorenzo Allievi. In water VAPOR flow, the condensation of steam due to EXPANSION and the resulting cooling can remain in flow but the increased density will carry additional momentum that will be released in another form of ENERGY when impacting a WALL of the tube system (curve, flange or valve). This phenomenon can be solved in two different ways, as an INCOMPRESSIBLE FLUID, or as a compressible fluid. When the kinetic event is gradual (e.g., slow valve closure), the FLUID may be considered as incompressible with the maximum pressure ($P_{\max}$) in the fluid-filled tube using the rigid column theory: $F_{\text{hammer}} = AP_{\max} = A((v_f L/t) + P_i)$, where P_i is the inlet pressure, v_f is the flow velocity, t is the VALVE closing time in seconds, and L is the PIPE length leading up to the event. Note that A is the area of the obstruction. Any sudden/instantaneous change in flow conditions or abrupt closure of the valve will incorporate the compressibility of the medium in flow primarily with respect to the role of the WAVE speed propagation. The force exerted by the fluid compartment in free flow is calculated by the JOUKOWSKY EQUATION, where the change in force yields: $\Delta F = (dP/dt)A_{\text{surface}} = \rho v_w (dv_f/dt)A_{\text{surface}}$, where v_w is the SPEED OF WAVE PROPAGATION in the fluid, ρ the density of the fluid, and v_f the velocity of flow on closure or impact on the surface area A_{surface} that equals the maximum force exerted since the impact force is initially zero (open) (see Figure W.11).

Figure W.11 Water hammer as the mechanism of action in a pressure-washer system.

Water reactor

[nuclear, thermodynamics] Modern NUCLEAR REACTOR with ordinary water as the MODERATOR under pressurized conditions. A separate CIRCULATION system with a LIQUID coolant transfers the ENERGY generated by the FISSION process to a third system that powers a steam TURBINE electrical GENERATOR (see NUCLEAR REACTOR).

Water wave

[electronics, general, mechanics] Water waves are generated because of the fact that the surface is disturbed by the shear stress force resulting from the wind with a component perpendicular to the normal to the water surface. There is a minimum wind speed of $v \geq 1.1$ m/s that needs to be exceeded to affect the surface. The flow of AIR over the water surface creates pressure gradients based on the Bernoulli principles that cause the surface to break out and allow the parallel component of the wind to apply a force directly

on the protruding ripples. Under uniform and continuous exposure over a significant area of water surface, the height of the surface elevation departing from equilibrium (b_s) will develop a FREQUENCY (ν) spectrum profile that is primarily a function of the wind velocity, expressed as $b_s(\nu) = A_w(g^2/\nu^5)\exp(-1.25[\nu_m/\nu]^4)$, where $A_w = 5.2 \times 10^{-6}$ is a constant, $\nu_m = 0.13 g/U_w$ is the frequency of the central peak of the spectrum, with U_w the wind velocity at 10 m above the water surface, and g the GRAVITATION acceleration. The length of the surface area minimally subjected to the surface wind shear stress is referred to as the fetch. Near the coast line with a wind blowing off-shore the fetch is limited, and both the constant (A_w) and central peak frequency (ν_m) become a function of the fetch. Due to the viscosity of the water, there is a nonlinearity in propagation (specifically nonlinear acceleration) where the short waves are damped more dramatically than long waves, resulting in long propagation distances for low-frequency waves, that is, swells (e.g., $\nu \sim 0.10$ Hz yields undisturbed waves over thousands of kilometers with little loss of ENERGY). Waves propagating in the opposite direction of a local water current will concurrently grow in height. Due to various conditions, the waves generated in one direction will not necessarily remain confined and generally will spread out angularly over the surface (θ , with respect to the original path of the wind or the primary WAVE direction) similar to a Lambertian angular distribution of LIGHT emitted from a surface approximated by the following mathematical formulation: $b_s(\nu, \theta) = b_s(\nu)(2/\pi)\cos^2 \theta$; $\theta \leq (\pi/2)$ and $b_s(\nu, \theta) = 0$; $\theta > (\pi/2)$ (see TROCHOIDAL WAVE; also see SURFACE WAVE, CAPILLARY WAVES, SURFACE WAVES, TIDAL WAVES, and WAVE) (see Figure W.12).

Figure W.12 Water wave.

Water wheel, power

[fluid dynamics] Consider a centrifugal blade-pump. The TORQUE (T) applied to the scoops is directly proportional to the force resulting from the FLUID between sections A_1 and A_2 , expressed as $T = m(r_2 v_2 \cos \alpha_2 - r_1 v_1 \cos \alpha_1)$, where α_i is the ANGLE with the reference frame with regard to the absolute velocity vectors u_1 and u_2 respectively, r_i the respective radii at the inner (1) and outer (2) area of the scoop with mass flow rate m along the blade. In this way, the torque on the impeller shaft can be derived from the states of

the fluids, respectively the velocities on the inlet and the outlet relative to the impeller. Combining the ANGULAR VELOCITY (ω) of the impeller with the torque yields the POWER (P) to the shaft as $P = T\omega$ (see [Figure W.13](#)).

Figure W.13 (a) Water wheel; water wheel used to generate power, and water wheel as a mechanism of propulsion in the shape of a river boat paddle wheel (b).

Waterspout

[fluid dynamics, geophysics, meteorology] Updraft of water from a large water reservoir (lake, ocean), under an ATMOSPHERIC PRESSURE VORTEX. The pressure VORTEX is the result of the merging of two or more atmospheric pressure systems, generating a relatively small, confined rotational flow of AIR (air flowing from high- to low-pressure systems). The greatest ACTIVITY for water spout formation is over the Florida Keys in Florida. Larger waterspout contains more kinetic ENERGY and subsequently have a longer life-time. Waterspouts on the northern hemisphere generally rotate counter clockwise and on the southern hemisphere clockwise, due to the influence of the Coriolis forces. Occasionally the rotation will be clockwise on the northern hemisphere, as a result of the prevailing climatological conditions. Water VAPOR condensation provides an additional source of energy that fuels the TORNADO/waterspout mechanism of action (see [Figure W.14](#)).

Figure W.14 Waterspout.

Watson, James Dewey (1928–)

[general] Biologist (specialty: microbiology) and zoologist from the United States. James Watson and the scientist from Great Britain FRANCIS HARRY COMPTON CRICK (1916–2004) published the discovery of the double helix configuration of DNA in 1953, which makes up the human biological characteristics. Together with the third person, the physicist and biologist from New Zealand, MAURICE HUGH FREDERICK WILKINS (1916–2004), they received the Nobel Prize in Physiology/Medicine for their discovery in 1962 (see [Figure W.15](#)).

Figure W.15 James Dewey Watson [general], (1928–). (Courtesy of National Institutes of Health (NIH), Bethesda, MD.)

Watt, James (1736–1819)

[general] Scottish mechanical engineer and instrument maker by training, initially associated with the University of Glasgow. Watt never obtained the master title and was forced to seek employment outside the instrument maker guild's role of influence. He was a major contributor to developmental improvements to the recently introduced steam ENGINE developed by Thomas Newcomen in the early stages of the industrial revolution. At the AGE of 36, he partnered with Matthew Boulton to manufacture steam engines. His steam engine work inspired the development of the unit of power, the horse power (hp), later renamed after him as a credit to his contributions in the refinements to the steam engine (see [Figure W.16](#)).

Figure W.16 James Watt (1736–1819). (Courtesy of C. E. Wagstaff.)

Watt (W)

[general] The unit of power introduced by JAMES WATT in 1783, the horse power (hp), was derived from the fact that by general observation a horse walking at 2.5 miles per hour could consistently pull 150 lb of mass, but is currently officially replaced by the watt (W) as a unit for power; $1 \text{ hp} = 550 \text{ ft}(\text{lb}/\text{s}) = 746 \text{ W} = 0.746 \text{ kW}$. The watt is also defined as ENERGY (i.e., joule) per SECOND: ($1 \text{ W} = 1 \text{ J/s}$).

Wave

[electronics, fluid dynamics, general, mechanics] Periodic phenomenon with specific, unique spatial or temporal profile, generally propagating with a velocity that is defined by both the WAVE mechanism and the local conditions for the medium of propagation. A wave is an ENERGY fluctuation with a fixed frequency, operating around a general EQUILIBRIUM STATE. Mechanical waves rely on the displacement of a medium, either as a transverse or LONGITUDINAL WAVE; TRANSVERSE WAVES appear in surfaces or structures (rope), whereas longitudinal waves are for instance pressure waves. A wave is part of an OSCILLATION. Mechanical waves are for instance water waves, SEISMIC shear waves (s-waves; part of EARTHQUAKE), waves in a rope, as well as sound waves. Another wave action is found in electromagnetic waves. Depending on the mechanism of action for the wave formation and propagation, the wave will conform to either then MECHANICAL WAVE equation, expressed in a one-dimensional format for a wave with displacement u traveling in the x -direction with velocity v as a function of time (t): $(1/v^2)(\partial^2 u / \partial t^2) = (\partial^2 u / \partial x^2)$; or the electromagnetic MAXWELL EQUATIONS. The general SOLUTION to the WAVE EQUATION travels in two opposite directions and has the format: $u(x, t) = u_0 \exp(\pm kx - \omega t + \phi)$, where $k = 2\pi/\lambda$ is the wavenumber, with λ the wavelength, and $\omega = 2\pi\nu$ the ANGULAR FREQUENCY, with ν the FREQUENCY (the period $[T]$ of the wave is linked to the frequency as $T = 1/\nu$), and ϕ is a location-specific phase shift. Individual waves are subject to the superposition principle, adding the respective local displacement/magnitude or electric/magnetic energy magnitude from all waves converging in one location. Another wave phenomenon, directly related to superposition is INTERFERENCE, where identical waves will depend on the superposition principle to provide PHASE information about the merging waves, specifically the respective difference in phase. A group of waves with various wavelengths traveling together propagate with the group velocity ($v_g = \partial\omega/\partial k|_{\omega=\omega'}$, with ω' the “central” frequency of the spectrum), whereas the individual waves travel with the PHASE VELOCITY ($v_p = \omega/k$). Group and phase velocities can be different, which results in DISPERSION. The MAGNITUDE of a wave phenomenon is generally expressed by means of the square of the maximum AMPLITUDE of the wave, the intensity; however, electromagnetic waves have two mechanisms that are at orthogonal directions and require a different means of quantifying the magnitude and use “fluence” or “radiance” as the parameter. A single waveform is identified by a sinusoidal expression, and in physical form will resemble a sinus function; under superposition, the addition of a broad range of frequencies can yield specific waveforms, for instance: sawtooth, square, or triangular. Electronically another phenomenon is introduced, the rectified wave, which has no negative deflection. A standing wave is the result of the superposition of two identical waves traveling under well-defined boundary conditions adding to a wave that does not migrate; the crests remain in single

respective locations. For an open tube, the crest/through (maximum displacement in either direction) will be at the opening (for instance an acoustic wave in a tube or the free end of a string) by definition, similarly for a closed tube (SOUND) the zero-displacement “node” (equilibrium-point) will be at the closed end WALL, or the attached part of the string. For electromagnetic waves, the direction of the electric field defines the POLARIZATION direction of the RADIATION. The flow of water from a faucet consists of a superposition of a multitude of waves, creating interference. The three-dimensional interference in the water flow will make the stream appear as turning throughout its flow process, or it will make the stream expand and contract, next to a multitude of other visible wave and fluid-dynamic phenomena (*also see BEAT FREQUENCY and AIR WAVES*). See TIDAL WAVES, TIDAL BORE, TROCHOIDAL WAVE, WATER WAVES, HARMONIC OSCILLATION, and VIBRATION (see Figure W.17).

Figure W.17 Wave.

Wave dispersion

[acoustics, biomedical, biophysics, electromagnetism, engineering, fluid dynamics, general, geophysics, mechanics, optics, theoretical, ultrafast phenomenon] (syn.: crest, LIGHT, SOUND, surf, TIDAL WAVE, spatial domain fluctuations) {use: energy, imaging, spectroscopy} Wave propagation is controlled by various factors, such as liquid DENSITY (ρ) and discontinuities in the path. Wave dispersion is directly correlated to the definition of the GROUP VELOCITY OF WAVES: $v_g = d\omega/dk$. In GEOPHYSICS, the wave pattern produces a phenomenon called surf that is the result of the interrelation of the FREQUENCY (f) or WAVELENGTH (λ) (since: $f = v/\lambda$) and the average depth of the liquid level h_a , providing a dependency of the speed of propagation (v). The phase velocity of surface waves ($v_{p,s}$). The wave dispersion is caused by the phase velocity dependence on depth which in turn is also a function of wavelength. The phase velocity of SURFACE WAVES is gives as $v_{p,s} = \sqrt{((g\lambda/2\pi) + (2\pi T_s/\rho\lambda)) \tanh(2\pi h_a/\lambda)}$, where g is the GRAVITATIONAL ACCELERATION, T_s is the liquid surface tension in the liquid surface under disturbed equilibrium conditions, and ρ the liquid density. The higher order Fourier components will have a higher speed of propagation as a result of a nonlinearity in acceleration (*also see SURFACE WAVES*) and will thus “run away” from the lower frequencies, creating a breaking wave approaching the shore. Generally the phase velocity equation can be reduced based on the boundary conditions; for instance, for long waves in deep water, the PHASE VELOCITY ($v_{p,s}$) for GRAVITATIONAL WAVES reduces to $v_{p,s} = \sqrt{(g\lambda/2\pi)}$, where: $\omega = 2\pi/T =$ angular frequency $= 2\pi v$ and the wavenumber $k = 2\pi/\lambda$. MATERIAL DISPERSION: wavelength dependence on the REFRACTIVE INDEX (n). Wave GROUP VELOCITY (v_g) will depend on the material properties, that is, the (localized) index of refraction. When the group velocity is smaller than the phase velocity ($v_g < v_p$), there is normal dispersion since $(dn/d\omega) > 0$. When the group velocity is greater than the phase velocity ($v_g > v_p$), the propagation suffers from anomalous dispersion. The group velocity for longitudinal propagation related to material dispersion is described by filling in the parameter definitions in the equation for group velocity:

$v_g = d\omega/dk = c/[n + \omega(dn/d\omega)]$ revealing a dependence on the index of refraction of the medium, which may vary locally based on material properties and temperature effects (*also see* SURFACE WAVE, MASS–SPRING SYSTEM *and see* DISPERSION) (see Figure W.18).

Figure W.18 Wave dispersion.

Wave energy

[electromagnetism, fluid dynamics, mechanics] The ENERGY of a WATER WAVE is proportional to the square of the height of the WAVE with respect to “sea level,” expressed as $U = (1/8)\rho g h^2$, where ρ is the LIQUID density and g is the local GRAVITATIONAL ACCELERATION. For electromagnetic waves, the energy is defined by the pointing vector as a function of the MAGNETIC FIELD strength and electric field strength: $\vec{S} = \sqrt{\epsilon_0 \mu_0} / 4\pi (\vec{E} \times \vec{B})$, units: W/m^2 , $c = \sqrt{\epsilon_0 \mu_0}$ the speed of LIGHT, ϵ_0 the DIELECTRIC permeability of VACUUM, and μ_0 the dielectric permittivity. Acoustic wave energy is expressed as $E = I/v_s = v^2 \rho = P_{ac}/v_s A$, where I is the intensity of the SOUND, v_s the speed of sound, P_{ac} the acoustic pressure at the crest, A the area on which the acoustic wave is impinging, v the PARTICLE velocity of the medium in the wave, and ρ the density of the medium in which the wave travels.

Wave equation

[mechanics, nuclear, quantum] Correlation between displacement as a function of location and elapsed time $\nabla^2 \Psi = -(1/v^2)(\partial^2 \Psi / \partial t^2)$, where ∇^2 is the Laplace operator (i.e., second-order differential operator in the n -dimensional EUCLIDEAN SPACE), the derivative in all relevant spatial coordinates, Ψ the function describing the phenomenon (e.g., electric or MAGNETIC FIELD, position), t the time, and v the propagation velocity of the phenomenon. For linear WAVE problems (small AMPLITUDE approximation), one can consider FOURIER SERIES decomposition of any complicated surface elevation pattern, and this leads to the study of the simple Fourier components of $\sin(\lambda x - ct)$ and $\cos(\lambda x - ct)$ (*also see* SCHRÖDINGER EQUATION).

Wave motion

[general, mechanics] The progressive disturbance propagated in a medium by a periodic vibration of the particles of the medium. Transverse wave motion is that in which the VIBRATION of the particles is perpendicular to the direction of propagation. Longitudinal wave motion is that in which the vibration of the particles is parallel to the direction of propagation (*see* WAVE).

Wave number (k)

[atomic, nuclear, optics] Abbreviated from “angular wave number,” defined as $k = 2\pi/\lambda$, with λ the wavelength of the electromagnetic RADIATION. The standard use of WAVE number identifies the spatial frequency of an OSCILLATION in the direction of travel (units, radians per meter). The historical significance of the wave number is the MAGNITUDE of the momentum of a wave in the direction of propagation $k = |\vec{k}| = |\vec{p}|/\hbar$ (where $\vec{p} = (E/c)\vec{e}_t = \hbar\nu/c$, with E representing the ENERGY, and $\vec{e}_t$ the direction of travel). In SPECTROSCOPY, the “ordinary wave number,” defined as $1/\lambda = k/2\pi = \nu/c$ ($c = 2.99792458 \times 10^8$ m/s being the speed of LIGHT, and ν the frequency), is used to specify spectral lines in cm^{-1} . The ordinary wave number spells out the number of wavelengths per DISTANCE, and is an expression of energy content.

Wave particle duality

[electromagnetism, nuclear, optics] The concept of LIGHT as a particle was proposed by SIR ISAAC NEWTON (1642–1727), expressed in 1704 in his work “Opticks” (with a rudimentary introduction in his “Principia” in 1687). This followed on CHRISTIAAN HUYGENS’s (1629–1695) proposition describing light as acting as a WAVE phenomenon in 1678. The particle concept was based on the ideas of ROBERT HOOKE (1635–1703). Newton’s particle theory was however based on the AETHER concept, but still holds true for pure ENERGY. Newton’s particle theory (the corpuscular theory of light) surpassed the wave theory and was generally accepted until THOMAS YOUNG (1773–1829) illustrated the concept of INTERFERENCE (e.g., DOUBLE-SLIT EXPERIMENT) in 1801, almost 100 years later. Meanwhile the experimental work by the scientists ARMAND HIPPOLYTE LOUIS FIZEAU (1819–1896) and JEAN BERNARD LÉON FOUCAULT (1819–1868), both from France, in 1850 revealed that the speed of light is different for different media, placing the PARTICLE definition in discredit, but it was still not abandoned. The theoretical work by the scientist from Scotland, Great Britain, JAMES CLERK MAXWELL (1831–1879), provided additional insights into the wave–particle duality, but did not fully convince the scientific community of the full extent of this concept. The particle model still held firm through the mid-1800, but the full duality was not fully understood until the 1920 experiments from the US physicist ARTHUR HOLLY COMPTON (1892–1962), who proved a particle phenomenon of photons: momentum. This provided the support to introduce the theory that matter and energy are interchangeable. In the same period, in 1923, the scientist and aristocrat PRINCE LOUIS VICTOR PIERRE RAMOND DE BROGLIE (1892–1987) from France, proposed that both MATTER and RADIATION have properties that equate to both a particle and a wave phenomenon (*also see* WAVELENGTH, DE BROGLIE).

Wave propagation speed

[biomedical, fluid dynamics, mechanics] The speed of propagation of waves can be described for various conditions; however, the basic definition is the rate of change in traversed DISTANCE: $v = dx/dt$, which is compounded by a host of material and WAVE characteristics. For mechanical waves, the following conditions can be distinguished: free medium (e.g., GAS), transverse wave in a stretched string, solids, and liquids. For a free medium, the speed of propagations is given as $v = v\lambda$, with v the frequency and λ the wavelength; string under tension: $v = \sqrt{F_t/m_L}$, with F_t the tensile force on the string and m the mass per unit length of the string; longitudinal density wave in LIQUID: $v = \sqrt{B/\rho}$ (also accounts for EARTHQUAKE mantle-wave propagation) with ρ the density and B the BULK MODULUS ($B = \Delta P/(\Delta V/V_0)$; pressure P and volume V); longitudinal density wave in gas: $v = \sqrt{\gamma P/\rho}$ with P the local gas pressure and γ a thermodynamic constant defined by the ratio of the SPECIFIC HEAT at constant pressure and at constant volume of the gas respectively ($\gamma = c_p/c_v$), which reduces to $v = \sqrt{P/\rho}$ for ideal gasses, taking the temperature dependence in consideration this becomes $v = v_0\sqrt{1 + (T_c/T_0)}$, where v_0 is the speed at the reference temperature ($T_0 = 0^\circ\text{C}$), and T_c the temperature of the IDEAL GAS ($^\circ\text{C}$); longitudinal compression wave in elastic and rigid solids: $v = \sqrt{Y/\rho}$ with Y the Young’s modulus. In terms of TRANSVERSE WAVES, the speed for electromagnetic radiation is

defined as $c = 1/\sqrt{\epsilon_0\mu_0}$, with ϵ_0 the (DIELECTRIC) permittivity and μ_0 the (dielectric) permeability, both in VACUUM. Also $v = c/v\lambda$, in vacuum; $v = v(\lambda_0/n) = c/n$, in the medium with n the local index of refraction, λ the wavelength (sub zero in vacuum).

Wavefront

[general] The graphical and physical connections between points that are in the same PHASE and time stamp of a WAVE pattern. For instance, the (cylindrically symmetric) curve connecting all points of a radially expanding wave resulting from a centrally located perturbation. For LIGHT, the wavefront may be composed of a range of frequencies; considering a single wavelength, the wavefront for a oscillating source will form a spherically symmetric shell that travels outward, for a laser the wavefront will be within the beam only and travel in unison across the diameter of the beam as part of the coherence conditions associated with laser light.

Wavefunction

[nuclear] The SOLUTION to the SCHRÖDINGER WAVE EQUATION in the DE BROGLIE WAVE model for a PARTICLE: $\Psi = \Psi(x, y, z, t) = \psi(x, y, z)\tau(t) = C_1\psi(x, y, z)e^{-iE/\hbar} = C_1\psi(x, y, z)e^{-i\omega t}$. The wavefunction has the following properties: (1) it must be single valued, (2) it must be continuous everywhere, and (3) the first respective partial derivatives must be continuous. The first partial derivatives for all components are directly related to the particle FLUX, that is, the quantity of particles intercepting per unit cross-sectional area at a given point in time (removing the time dependence).

Wavelength (λ)

[general, mechanics, solid-state] The DISTANCE traveled by a WAVE over the duration of one period (T) defined as $\lambda = vT = v/v = c/v$, with v the speed of propagation (c for light) and v the frequency of OSCILLATION. This temporal definition translates into the following spatial definition: the linear distance between any two similar points of two consecutive wave segments, for example, crest or trough, compression or expansion (i.e., rarefactions). The wavelength on a string is connected to the POTENTIAL ENERGY (PE_λ) and kinetic energy (KE_λ) in the string under the external force vibrating with AMPLITUDE A and ANGULAR FREQUENCY ($\omega = 2\pi v$), defined by the total energy stored in one wavelength: $E_\lambda = PE_\lambda + KE_\lambda = (1/2)m_L\omega^2 A^2\lambda$, where m_L is the mass per unit length of the string. This converts for a gas into: $E_\lambda = PE_\lambda + KE_\lambda = (1/2)\rho A(s_{\max}\omega)^2\lambda$, where ρ is the density of the gaseous medium and s the transverse displacement with amplitude: $s_{\max} = \Delta P_{\max}/\rho v\omega$, where $\Delta P_{\max}$ is the maximum deviation in pressure from equilibrium in the wave pattern (i.e., full compression or maximum rarefaction). A standing wave in a string or a tube with length L with both ends fixed/closed satisfies $n(\lambda/2) = L$, whereas when one of the ends is loose or open, this becomes: $n(\lambda/4) = L$, with n an integer >0 . In a disk, the process becomes more involved due to the various modes of standing waves in the area (e.g., drum, tambourine, xylophone, or cymbals). In case the membrane is symmetric with radius R , the standing waves need to satisfy the following conditions in cylindrical coordinates (due to symmetry; radial and angular, only two-dimensional): $\lambda^2 r^2 + [r^2/J_0(r(\alpha_{0n}/R))][d^2 J_0(r(\alpha_{0n}/R))/dr^2] + [r/J_0(r(\alpha_{0n}/R))][dJ_0(r(\alpha_{0n}/R))/dr] = \text{Constant} \Rightarrow m^2$, as well as $-(1/\Omega(\omega))(d^2 \Omega(\omega)/d\theta) = \text{Constant} \Rightarrow m^2$, where $J_0(r(\alpha_{0n}/R))$ is a Bessel function of order 0, r the radius of the membrane or plate, α_{0n} are roots of the Bessel function ($n = 1, 2, 3, \dots$), where $\lambda R \propto \alpha_{0n}$. With solutions to the angular equation $\Omega(\omega) = C_1 \cos m\theta + C_1 \sin m\theta$; C_i and m are constants. Light consisting of one single wavelength is considered monochromatic. The wavelength of the LIGHT emitted from an excited atomic state during the regrouping of electrons in the GROUND STATE is derived from the CONSERVATION OF ENERGY for the degenerating ATOM as $1/\lambda = (2\pi^2 k_0^2 e^4 m_e Z^2 / h^3 c) [(1/n_f^2) - (1/n_i^2)]$, where the electron decays from the initial

(n_i) energy level indicated by $E_n = (2\pi^2 k_0^2 e^4 m_e / h^2) [Z^2 / n_i^2]$, with k_0 the material constant for VACUUM ($k_0 = 1/4\pi\epsilon_0 = 8.98755179 \times 10^9$, ϵ_0 the permittivity of vacuum), e the electron charge, m_e , the electron mass, h PLANCK'S CONSTANT, and Z is the atomic number, or the number of protons. This expression holds for the Lyman, Balmer, and PASCHEN SERIES (see Figure W.19).

Figure W.19 Waveforms, in particular, modes of vibration for a circular thin sheet (e.g., drum skin, metal surface of a drum, and plastic area of the bottom of a bucket).

Wavelength, de Broglie

[atomic, nuclear] Based on the principle that every moving object has an associated DE BROGLIE WAVELENGTH λ_d tied to the momentum of a particle (p) to the inherent wavelength as $\lambda_d = h/p$, where h is PLANCK'S CONSTANT. For PROTON and neutron with $v \ll c$, this translates into $\lambda_d = 28.6/\sqrt{\text{KE}}$ (in MeV), units fm.

Weak force

[general] See WEAK INTERACTION (also see VAN DER WAALS FORCE).

Weak interaction

[atomic, computational, electromagnetism, general, quantum, theoretical] The weak interaction is described as a weak-interaction density distribution ($\mathcal{L}_W$) with the Lagrangian formulated in vectorial quantities as $\mathcal{L}_W = -(G/\sqrt{2}) J_\alpha^\dagger(x) J^\alpha(x)$, where $J^\alpha(x)$ represents the charge current, $J_\alpha^\dagger(x)$ the current equivalence for raising a charge in a transition such as from n -state to p -state, and G is the gravitational constant. The current is described by polar and axial terms as illustrated by the charged weak current for leptons: $J_{\text{lept}}^\alpha(x) = \bar{e} \gamma^\alpha (1 - \gamma_5) \nu_e + \bar{\mu} \gamma^\alpha (1 - \gamma_5) \nu_\mu + \bar{\tau} \gamma^\alpha (1 - \gamma_5) \nu_\tau$, where the leptons are $\bar{e}$ is the electron; ν_e the electron neutrino; $\bar{\mu}$ the MUON; ν_μ the muon neutrino and $\bar{\tau}$ the third charged LEPTON,

tau (the heaviest); and ν_τ the “third-lepton/tau” NEUTRINO, with $\gamma_\Sigma = i\gamma^0\gamma^1\gamma^2\gamma^3\gamma^4$ the current matrix with partial SCALAR terms (*also see FEYNMAN DIAGRAM*) (see [Figure W.20](#)).

Diagram of one of several potential weak interaction decay processes

Figure W.20 Example of the concept of weak interaction.

Weber, Ernst Heinrich (1795–1878)

[biomedical, general] Physicist and scientist from Prussia (Germany). Apart from his work as a physician, Heinrich was interested in the scientific work of his brother WILHELM EDUARD WEBER (1804–1891), and together they described the culmination of two WAVE trains (sequence of wavefronts) to form a standing wave, which was made visible by mercury spread out over a sheet that was excited by acoustic (mechanical) waves from opposite sides. The mercury would under certain conditions pool in fixed locations, the nodes of the standing wave. Ernst Weber was interested in human locomotion and in particular the PHYSICS aspects of walking (see [Figure W.21](#)).

Figure W.21 Ernst Heinrich Weber (1795–1878). (Courtesy of Max Planck Institute for the History of Science, Berlin, Germany; lithographie von Rudolf Hoffmann, 1856; Österreichische Nationalbibliothek, Vienna; Austria.)

Weber, Wilhelm Eduard (1804–1891)

[general] Scientist and mathematician from Prussia (Germany). Wilhelm Weber was influenced by the work of his contemporary JOHANN FRIEDRICH PFAFF (1765–1825) as well as CARL FRIEDRICH GAUSS (Gauß; 1777–1855). Next to the acoustic work with his brother ERNST HEINRICH WEBER (1795–1878),

Wilhelm Weber worked on the MAGNETISM produced by an electric current and MAGNETIC radiation in general. Wilhelm Weber was responsible for designing a mechanism to quantify magnetic flux and the unit was named after his work performed in 1821, the weber. Additional work of Wilhelm Weber was in collaboration with Friedrich Gauss, which produced the first electromagnetic TELEGRAPH machine, used for long-distance communications. Wilhelm Weber also provided support for the observations by HIPPOLYTE FIZEAU (1819–1896) with his experimental conclusions in 1856, supporting the rudimentary formation of the WAVE–particle duality concept, as well as providing components for the theoretical efforts of JAMES CLERK MAXWELL (1831–1879). One of Wilhelm Weber’s pupils was the German mathematician Georg Friedrich Bernhard Riemann (1826–1866) (see [Figure W.22](#)).

Figure W.22 Wilhelm Eduard Weber (1804–1891). (Courtesy of Max Planck Institute for the History of Science, Berlin, Germany.)

Weber (Wb)

[general, electromagnetism] Unit of magnetic FLUX, $\text{Wb} = \text{Tesla}/\text{m}^2$, named after WILHELM EDUARD WEBER (1804–1891). The MAGNITUDE of magnetic flux is tied to the FARADAY LAW.

Weber number ($We = \text{Const}(\rho v^2 L / \sigma)$)

[fluid dynamics] Ratio of the inertial force to the SURFACE TENSION expressed as a dimensionless number, with the help of a dimensional constant, Const, where ρ is the density, v the velocity (for instance the velocity at impact on a surface where the droplet will experience the surface tension), L the characteristic length of the phenomenon (e.g., droplet diameter), and σ the surface tension. The Weber number is used to scale the phenomena in droplet formation, LIQUID jets, and momentum transfer in general. Under certain Weber number conditions, a water JET can be created, known as a WORTHINGTON JET.

Wedgwood, Josiah (1730–1795)

[general, solid-state] Material scientist (ceramist and potter) from Great Britain. The observations of Thomas Wedgwood as a manufacturer of fine china also made him interested in the physical aspects of the material treatment process. In 1792 Wedgwood described the thermal RADIATION associated with objects in a kiln, outlining the concepts of black-body radiation, well before the publication of the Kirchhoff

radiation law in 1859. GUSTAV KIRCHHOFF (1824–1887) added his own theoretical contributions and provided physical proof in 1861 (see [Figure W.23](#)).

Figure W.23 Josiah Wedgwood (1730–1795). (Courtesy of the photographer Stephen Betteridge.)

Weight (F_w)

[general] The force on a body resulting from a gravitational pull. Note that mass is a material property, but weight is a function of GRAVITATIONAL ACCELERATION.

Weinberg, Steven (1932–)

[general] Physicist from the United States, best known for his theoretical work on electroweak interaction. Steven Weinberg received the Nobel Prize in physics for his work on unified weak and electromagnetic interaction between ELEMENTARY PARTICLES with SHELDON LEE GLASHOW (1932–) and Abdus Salam (1926–1996) in 1979 (see [Figure W.24](#)).

Figure W.24 Steven Weinberg (1932–).

Weir, John B. de V. (?–?, twentieth century)

[biomedical, chemical, energy] Physiologist from Great Britain. Weir is most known for his analysis of ENERGY production based on oxygen (O_2) consumption in metabolic reactions, producing carbon dioxide (CO_2). Weir described the energy production independently for carbohydrates, proteins, and fatty constituents in three equations based on measurable quantities of chemical reagents fueling the reaction and products from the reaction. The resting energy equation is known as the WEIR EQUATION.

Weir equation

[biomedical, chemical] Heuristic formulation of the ENERGY expenditure ($E_{\text{metabolic}}$) from a protein and/or CARBOHYDRATE oxidation chemical reaction based on volumetric oxygen intake (V_{O_2}), volumetric carbon dioxide production (V_{CO_2}), as well as nitrogen volume equivalent released in the urine (M''_N), calculated per liter of oxygen. The Weir equation used nowadays combines the three influences and is expressed in Kcal/L as $E_{\text{metabolic}} = 3.941 + 1.106(V_{CO_2}/V_{O_2}) - 2.17(M''_N/V_{O_2})$. Derived by JOHN B. DE V. WEIR in 1948.

Weissenberg, Karl (1893–1976)

[fluid dynamics, imaging] Physicist and mathematician from Austria. Karl Weissenberg was involved in the definition of the X-RAY diffraction crystallography for which he devised a goniometer in addition to his work in RHEOLOGY (see [Figure W.25](#)).

Figure W.25 Karl Weissenberg (1893–1976).

Weissenberg number, ($Wi = t_f |\vec{v}|/D$)

[fluid dynamics] Dimensionless number used in VISCOELASTIC (i.e., non-Newtonian) flow as an indication of anisotropy resulting from flow deformation under a constant stress. The Weissenberg number is used to scale the deformation rate describing the ratio of the RELAXATION TIME to the flow timescale: $Wi \sim (t_r/t_f)$, where $t_f = \sqrt{(\text{tr}(\dot{\epsilon}))^2/2} = \text{tr}(\dot{\epsilon})/\sqrt{2}$ describes the flow timescale, tr denotes TRACE, $\vec{v}$ the flow velocity, and D the PIPE diameter or characteristic size of the phenomenon. The flow timescale is dependent on the strain rate $\dot{\epsilon}$,

which is defined by the flow velocity with the CAUCHY STRAIN TENSOR as $\dot{\epsilon} = \nabla \vec{v} + (\nabla \vec{v})^T$ with T the transposed matrix. For a steady low REYNOLDS NUMBER shear flow, the flow time factor is a function of the shear rate (γ): $t_f = 1/\gamma$ describing simple shear, whereas the flow timescale for extensional flow is $t_f = 1/\epsilon$, where ϵ is the extension rate or strain of the flow. The Weissenberg number becomes important when the flow timescale for the viscoelastic FLUID is less than the relaxation time (τ_r), and elastic effects become dominant. The Weissenberg number is closely related to the DEBORAH NUMBER ($De = t_f |\vec{v}|/L = Wi(D/L)$), with L the length of the phenomenon or tube length), whereas the Deborah number refers to a nonconstant stretch.

Weisskopf, Victor Frederick (1908–2002)

[atomic, computational, general, nuclear] Physicist from Austria. Weisskopf was part of the MANHATTAN PROJECT team. Weisskopf contributed to the development of the QUANTUM THEORY and worked on the basic understanding of the ENERGY structure of the atomic NUCLEUS. Weisskopf also contributed to the calculation of the LAMB SHIFT (see Figure W.26).

Figure W.26 Victor Frederick Weisskopf (1908–2002). (Courtesy and copyright CERN®, Conseil Européen pour la Recherche Nucléaire [European Laboratory for Particle Physics], Geneva, Switzerland.)

Weisskopf half-life

[atomic] Theoretical estimation for the single ($_{sp}$) gamma photon (γ) HALF-LIFE ($\tau_{1/2}$) for either nuclear electric transitions or MAGNETIC transitions. The PROBABILITY of transition within a certain time frame is expressed for either electric (EL) or magnetic (ML) DECAY phenomena as $\tau_{1/2}(\gamma)(EL)_{sp} = [\ln(2) L \{ (2L+1)!! \}^2 \hbar] / [2(L+1) e^2 R^{2L}] [(3+L)/3]^2 (\hbar c / E_\gamma)^{2L+1}$ and $\tau_{1/2}(\gamma)(ML)_{sp} = [\ln(2) L \{ (2L+1)!! \}^2 \hbar] / [80(L+1) \mu_N^2 R^{2L-2}] [(3+L)/3]^2 (\hbar c / E_\gamma)^{2L+1}$ respectively, where $\hbar = h/2\pi$ with PLANCK'S CONSTANT $h = 6.62606957 \times 10^{-34} \text{ m}^2 \text{ kg/s}$, $R = 1.2 \times 10^{-13} \text{ A}^{1/3} \text{ cm}$ a constant, which is linked to the Bohr shell model, $e^2 = 1.440 \times 10^{-10} \text{ keV cm}$, $\mu_N^2 = 1.5922 \times 10^{-38} \text{ keV cm}^3$, L the orbital angular QUANTUM NUMBER for the transition, and $c = 2.99792458 \times 10^8 \text{ m/s}$ the speed of LIGHT.

Weisskopf single particle transition probability

[atomic] The theoretical PROBABILITY for the emission of a PHOTON resulting from a single PARTICLE degeneration based on the WEISSKOPF HALF-LIFE expressed as $P_{\text{prob}}(EL, ML)(W, u) = (\tau_{1/2}^\gamma(EL, ML)_{sp}) / (\tau_{1/2}^\gamma(EL, ML)_{\text{exp}})$.

Wentzel, Gregor (1898–1978)

[computational, general, quantum] Physicist and mathematician from Germany best known for his theoretical work on the QUANTUM THEORY of fields and fueled the development of QUANTUM MECHANICS. Together with the Dutch scientist HENDRIK KRAMERS (1894–1952) and the French physicist Léon Brillouin (1889–1969), they formulated the WKB solution (Wentzel–Kramers–Brillouin) model for solving the one-dimensional time-independent SCHRÖDINGER EQUATION in 1926 (see [Figure W.27](#)).

Figure W.27 Gregor Wentzel (1898–1978). (Courtesy of University of Leipzig, Leipzig, Germany.)

Wentzel–Kramers–Brillouin (WKB) solution method

[acoustics, computational, fluid dynamics, mechanics, quantum] Mathematical method for obtaining an approximate solution to the one-dimensional time-independent SCHRÖDINGER equation proposed by the German scientist GREGOR WENTZEL (1898–1978), the Dutch scientist HENDRIK ANTHONY KRAMERS (1894–1952), and the French physicist Léon Nicolas Brillouin (1889–1969) in 1926. This SOLUTION method specifically has QUANTUM MECHANICS applications, using a classical mechanics approach. The roots for this solution method date back to the French mathematician JOSEPH LIOUVILLE (1809–1882) from his work published in 1837.

Westinghouse, George (1846–1914)

[general] Engineer and entrepreneur from the United States known for his innovation and commercialization of electrical products and electrical support industry. George Westinghouse was an inventor and businessperson creating one of the largest electrical corporations at the early stages of electrical integration. George Westinghouse created the hydroelectric plant at Niagara Falls in 1896. One of George's inventions was the TRANSFORMER, allowing ELECTRICITY to be distributed and transmitted over long distances.

The Westinghouse Electric Corporation was created in 1886 and was a major player in the electric distribution network for the entire United States until it went defunct in 1999 (see [Figure W.28](#)).

Figure W.28 George Westinghouse (1846–1914), photograph by Joseph G. Gessford. (Courtesy of U.S. Library of Congress Prints and Photographs Division)

Wet-bulb temperature

[thermodynamics] Temperature recording made with a THERMOMETER that has the “bulb” (liquid reservoir with mercury, ALCOHOL, or other expanding LIQUID) covered with a wick that is soaked in water, and the device is placed in a stream of MOIST AIR. The term comes from the field of PSYCHROMETRY (ENGINEERING dedicated to the thermodynamic properties of gas–vapor mixtures).

Wheatstone, Charles (1802–1875)

[energy, optics] Engineer and scientist from the Great Britain. Sir Charles Wheatstone is known for several inventions, one being the electric TELEGRAPH, and even though Wheatstone did not invent the MICROPHONE he did bring the term in CIRCULATION in 1827. In 1838, Sir Wheatstone designed a mechanism to view images in three dimensions by means of an optical structure, generating the 3D illusion. Additional work of

Charles Wheatstone was in the determination of unknown electronic components, introducing the WHEATSTONE BRIDGE (see [Figure W.29](#)).

Figure W.29 Charles Wheatstone (1802–1875).

Wheatstone bridge

[energy] Electric balancing circuit designed by CHARLES WHEATSTONE (1802–1875) in order to determine the value of an undetermined resistor by placing it in a PARALLEL CIRCUIT with power supply and adjust other known resistor values to form a circuit that has no current flowing. The RESISTOR value is derived from $R_1/R_2 = R_3/R_4$ (see [Figure W.30](#)).

Figure W.30 Wheatstone bridge concept.

Wheeler, John Archibald (1911–2008)

[astrophysics/astronomy, atomic, computational, nuclear] Theoretical physicist from the United States. John Wheeler coined the term “BLACK HOLE” for phenomena in the UNIVERSE that seemed to have exceeding gravitational pull. Additional work by Wheeler was in the theoretical description of NUCLEAR FISSION in

collaboration with NIELS BOHR (1885–1962). One of Dr. Wheeler’s students was RICHARD FEYNMAN (1918–1988) (see [Figure W.31](#)).

Figure W.31 John Archibald Wheeler (1911–2008). (Courtesy of Princeton University, Princeton, NJ.)

White

[general, optics] Range of ELECTROMAGNETIC SPECTRUM covering the range blue through RED, perceived by the HUMAN EYE as white (see [Figure W.32](#)).

Figure W.32 White emission as the superposition of broad-band red, green, and blue light sources, in technicality covering the entire visible spectrum. Note that the combined paint of red, green, and blue dye will form a black appearance, whereas the lack of electromagnetic radiation absorbent dyes provides the reflected light of the superposition of all incident color wavelengths.

White dwarf

[astrophysics/astronomy, general] Medium size stars (with sizes less than eight times the size of our SUN) will degenerate into white dwarfs, processing through a stage of “RED GIANT” (for our Sun this object will have a diameter reaching the orbit of the planet EARTH) for approximately 1 billion years (in comparison to operating as a hydrogen FUSION STAR in the order of 10 billion years). Medium size stars are fusion engines producing helium from hydrogen in their cores. As the red giant collapses, the

helium will fuse into carbon and other heavier ELEMENTS. The first observation pertaining to a white dwarf was made by FRIEDRICH WILHELM BASEL (1784–1846) in 1844, with respect to his observations of Sirius, which was recognized as an unexplained anomaly. In 1863, Alvan Graham Clark (1804–1887) recognized this anomaly as a white dwarf. Large stars will degrade into NEUTRON stars or “black hole.” White dwarfs are extremely dense, approximately equivalent to the mass of our Sun compacted in the size of our Earth (see [Figure W.33](#)).

Figure W.33 Nova outburst with the White dwarf star in an orbit around a giant red star.

White light

[general] Temperature COLOR greater than 6000 K, broad range of emission wavelengths stretching from 340 nm or less through 650 nm or greater in the visible PERCEPTION. The SUN has an EMISSION SPECTRUM on the EARTH that equates to a black-body radiance of 5780 K, based on the Planckian radiator model (*also see* WIEN'S DISPLACEMENT LAW *and* CIE COLOR CHART).

White noise

[general] Indiscriminate and unsystematic arrangement of frequencies mixed in with the SIGNAL covering a broad wavelength range, with randomly fluctuating magnitudes as a function of frequency (see [Figure W.34](#)).

Figure W.34 Generalized frequency spectrum of White noise.

Wiedemann–Franz ratio

[atomic, nuclear, thermodynamics] See **LORENTZ NUMBER**.

Wien, Wilhelm Carl Werner Otto Fritz Franz (1864–1928)

[atomic, general, nuclear, thermodynamics] Scientist from the Prussian empire (Lithuania), known for his contributions to RADIATION spectra, specifically “black-body” radiation. Additional work of Wien contributed to a rudimentary model of the ATOM, based on the CATHODE ray interaction with atomic compounds, creating positive particles that are deflected by both electric and MAGNETIC fields. Since his work predates the QUANTUM THEORY, the close resemblance to quantum PHYSICS in his atomic model was remarkable. The empirical WIEN’S DISPLACEMENT LAW devised by Wilhelm Wien was adjusted by his colleague MAX PLANCK (1858–1947) to form the WIEN–PLANCK LAW, with a theoretical basis (see [Figure W.35](#)).

Figure W.35 Wilhelm Carl Werner Otto Fritz Franz Wien (1864–1928), along with the Swedish ophthalmologist Allvar Gullstrand (1862–1930).

Wien–Planck law

[atomic, nuclear, thermodynamics] RADIATION law theorized by MAX PLANCK (1858–1947), based on the work of his colleague WILHELM WIEN (1864–1928) in 1900. The Wien–Planck law, also referred to as the Planck radiation law provides a spectral distribution, accounting for the emission in the longer (low-energy) wavelengths expressed as $I_{\nu,T} = 2b\nu^3/c^2 \left\{ \exp(b\nu/k_bT) - 1 \right\}^{-1}$, which reduces to the WIEN’S DISPLACEMENT LAW when assuming $b\nu \gg k_bT$, where $I_{\nu,T}$ represents the energetic emission as a function of wavelength (with the associated frequency $\nu = c/\lambda$, with c the speed of LIGHT), at any specific wavelength, emitted per unit solid angle (Ω), as a function of

TEMPERATURE (T) per unit time (t) radiated over a normalized surface area (A), $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK'S CONSTANT, and the Boltzmann coefficient $k_b = 1.3806488 \times 10^{-23} \text{ m}^2\text{kg/s}^2\text{K}$ (see Figure W.36).

Figure W.36 Wien–Planck law.

Wien's displacement law

[atomic, nuclear, thermodynamics] RADIATION wavelength (emission peak in the distribution spectrum: λ_{peak}) versus temperature of the black-body (T) equivalence described by WILHELM WIEN (1864–1928) in 1893: $\lambda_{\text{peak}} T = \text{Const}$. In a greater detail, the energetic emission ($I_{\nu,T}$) spread out over a wavelength bandwidth, with a peak emission at λ_{peak} (with the associated frequency $\nu = c/\lambda$, with c the speed of light), per unit solid angle (Ω), as a function of temperature, per unit time (t) radiated over a normalized surface area (A) expressed as the spectral envelope function $I_{\nu,T} = (2b\nu^3/c^2)\exp(-b\nu/k_bT)$, with $b = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK'S CONSTANT and $k_b = 1.3806488 \times 10^{-23} \text{ m}^2\text{kg/s}^2\text{K}$ the Boltzmann coefficient (see Figure W.37).

Figure W.37 Wien's displacement law.

Wigner, Eugene (Jenő Pál) (1902–1995)

[atomic, computational, nuclear, quantum] Physicist and mathematician from Hungary. Jenő Pál Wigner received the Nobel Prize in Physics for his work on ELEMENTARY PARTICLES and the theoretical description of the atomic NUCLEUS in 1963, shared with MARIA GOEPPERT-MAYER (GÖPPERT) (1906–1972) and JOHANNES HANS DANIEL JENSEN (1907–1973). Jenő Pál Wigner may be considered one of the founding fathers of QUANTUM chemistry (see [Figure W.38](#)).

Figure W.38 Eugene (Jenő Pál) Wigner (1902–1995). (Courtesy of Oak Ridge National Laboratory, U.S. Department of Energy, Oak Ridge, TN.)

Wigner distribution

[atomic, computational, nuclear] Momentum PROBABILITY distribution function expressed in 1932 by JENŐ PÁL (EUGENE) WIGNER (1902–1995), defining the WAVEFUNCTION ($\psi(q)$, as a function of location q ; the wavefunction can contain electric and MAGNETIC FIELD) and the representative state of the medium in QUANTUM MECHANICS. The general Wigner distribution for the state of a system is defined as $W(q, p) = (1/\pi\hbar) \int_{-\infty}^{\infty} \psi^*(q+y) \psi(q-y) e^{i2py/\hbar} dy$ semiclassical $(1/\pi\hbar) \int_{-\infty}^{\infty} q-y \hat{\rho} |q+y e^{i2py/b} dy$, where $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34} \text{ m}^2\text{kg/s}$ the PLANCK'S CONSTANT, ψ^* is the complex conjugate, p the momentum, y the position in free space, and $\hat{\rho}$ a density matrix that can be applied for a classical mechanical approach. The Wigner distribution can be used to analyze audio signals and the representative audio PERCEPTION as well as electrocardiograms next to quantum mechanical applications. In classical mechanical terms, the Wigner distributions hold information about the FREQUENCY SPECTRUM the group delay and the response function.

Wilkins, Maurice Hugh Frederick (1916–2004)

[biomedical, general, imaging] Physicist and molecular biologist from New Zealand. In 1953, Maurice Wilkins provided the imagery to support the experimental and theoretical work by JAMES WATSON (1928–) and FRANCIS HARRY COMPTON CRICK (1916–2004) on their efforts in DNA analysis and the discovery of the nature of the genetic structure of living organisms. Wilkins shared the Nobel Prize in Physiology/Medicine

with Watson and Crick in 1962 for their groundbreaking efforts supporting biological development and function and physiological formatting (see [Figure W.39](#)).

Figure W.39 Maurice Hugh Frederick Wilkins (1916–2004). (Courtesy of National Institutes of Health, Bethesda, MD.)

Wilson, Charles Thomson Rees (1869–1959)

[atomic, nuclear] Physicist from Scotland, Great Britain. Inventor of the cloud chamber used for tracking and identifying charged particles, for which he received the Nobel Prize in Physics in 1927, which he shared with ARTHUR HOLLY COMPTON (1892–1962) (see [Figure W.40](#)).

(a)

(b)

Figure W.40 (a) Charles Thomson Rees Wilson (1869–1959), in 1927. (Courtesy of Electric Scotland Muskegon, MI, USA.) (b) In 1936 painting by Herbert James Gunn. (Courtesy of Sidney Sussex College, University of Cambridge; Cambridge, UK.)

Wilson cloud chamber

[atomic, nuclear] Condensation chamber that produces a trail of droplets in suspension according to the trajectory of a charged PARTICLE or charge interaction. Generally an external electric and/or MAGNETIC FIELD is applied to influence the path of the respective particles and allow for QUANTIFICATION of charge and mass. The Wilson cloud chamber has been credited with the aid in the discovery of the positron, the verification of the COMPTON SCATTERING of electrons, experimentally illustrated PAIR FORMATION and pair annihilation, next to the transmutation of atomic nuclei. The Wilson cloud chamber was recognized by ERNEST RUTHERFORD (1871–1937) as one of the most influential discoveries of the day. Also known as cloud chamber (see [Figure W.41](#)).

Figure W.41 Wilson cloud chamber. (Courtesy of Electric Scotland, Muskegon, MI, USA.)

Wimshurst, James (1832–1903)

[electronics, general] Engineer and scientist from Great Britain. Inventor of the WIMSHURST MACHINE, creating sparks through electrostatic charge build-up from rotating disks that have opposite revolution rubbing against copper brushes to conduct the charges off to either Leyden Jars or electrodes. James Wimshurst followed the example set out by the French scientist Ferdinand Philippe Edouard Carré (1824–1900), who also invented and designed refrigeration equipment, the German physicist Wilhelm Holtz (1836–1913), with his MACHINES exhibited in 1865 and 1867, as well as another German physicist, AUGUST JOSEPH IGNAZ TOEPLER (1836–1912) with his machine on display in 1865. Other inventors working on the same principle were by the German scientists ROGER VOSS (early eighteen hundreds) and J. ROBERT VOSS (early eighteen hundreds). James Wimshurst also invented a VACUUM machine. Other contributions by Wimshurst were in his field of nautical construction, devices to indicate the stability

of large ships and designed the manner in which a lighthouse in open sea could be powered by ELECTRICITY (see [Figure W.42](#)).

Figure W.42 James Wimshurst (1832–1903).

Wimshurst machine

[electronics, general] Electrostatic device made with two insulating disks that rotate in opposite directions and form nonfriction based electrostatic charge build-up (no contact to generate charge build-up except for the current wires). The machine was designed and constructed by JAMES WIMSHURST (1832–1903) in 1878. The insulating disks have small sections of conducting material at fixed intervals that are brought in contact with copper brushes when rotating. The electrostatic charge generated from the two disks is transferred to either electrodes which produce an arc, or to Leyden Jars for “storage.” The first primitive form of an electrostatic frictional machine was invented and fabricated by OTTO VON GUERICKE (1602–1682) in 1663. Various versions were created over the years, with a 1.6 m diameter set of GLASS disks in 1783 by the Dutch physicist and inventor Martin van Marum (1750–1837). The Van Marum disks had the capability to produce

electrical charge of either polarity, using FRICTION (*also see* VAN DE GRAAFF GENERATOR *and* TESLA COIL) (see [Figure W.43](#)).

Figure W.43 Wimshurst machine. (Courtesy Lateral Science Co., UK.)

Wing

[astrophysics, fluid dynamics, mechanics] Structure that provides a LIFT during a flight. Bird wings have a special construction where the feathers create the optimal conditions to support a lift and elevation as well as sustain a flight while allowing for minimal INTERFERENCE on the upward force during the up–down movement of the wings during ascension. Mammals with wings, such as bats, squirrels, and monkeys have no feathers and rely on the turning of the solid wing (e.g., SKIN, membrane) while undergoing upward MOTION to still take advantage of the Bernoulli principle, and not push the animal down. Insect wings are generally also constructed from a membrane; however, some wings can be very intricate, such as the butterfly and moth wing. For a fixed-wing aeroplane (airplane), the Bernoulli principle is applied to provide a lift as a result of the forward velocity, creating a pressure gradient that provides a lift that supports the airplane and its LOAD (*also see* LIFT) (see [Figure W.44](#)).

Figure W.44 Wing design.

Wollaston prism

[general, optics] Polarizing prism, and beam splitter. The Wollaston prism separates the ordinary and the extraordinary rays, both polarized in respective orthogonal directions. The extraordinary ray is polarized parallel to the long-axis planes of all windows, specifically of the separation plane. The DIVERGENCE between the ordinary and the extraordinary ray is a function of the ANGLE of the PRISM windows. The Wollaston prism finds applications in CD and DVD players in combination with a quarter-WAVE plate (see [Figure W.45](#)).

Figure W.45 Wollaston prism.

Womersley, John Ronald (1907–1958)

[biomedical, fluid dynamics] Physiologist and mathematician from Great Britain, known for his interpretation of viscous flow. Some of Womersley's major contributions have been to the fields of textiles and biomedical FLUID DYNAMICS. The work of Womersley expanded on the PULSATILE FLOW model developed by the German physiologist Otto Frank (1865–1944) based on the Windkessel phenomenon in 1899, integrating the Navier–Stokes equations (see [Figure W.46](#)).

Figure W.46 Computer conceived and produced by John Ronald Womersley (1907–1958).

Womersley number, ($\alpha_{wo} = r\sqrt{\rho\omega/\eta}$)

[biomedical, fluid dynamics] Dimensionless number used to scale the dominant features in a PULSATILE FLOW. The Womersley number is defined as the ratio of changing inertial forces resulting from the localized acceleration in each period of the pulsatile MOTION with respect to the viscous forces, where r is the radius of the conduit (BLOOD vessel, PIPE, etc.), ω is the ANGULAR VELOCITY due to changes in pressure gradient of the fluid in motion that is directly related to the FREQUENCY (ν) of the OSCILLATION ($\omega = 2\pi\nu$), ρ the fluid density, and η the VISCOSITY. In this approximation the elastic behavior of the WALL is considered to be negligible.

Wooster, William Alfred (Peter) (1903–1984)

[general] Scientist and mineralogist from the United States. The work of Wooster contributed to the material science aspects of crystallography.

Work (W)

[general, mechanics, nuclear] ENERGY resulting from a constant force F applied at an ANGLE θ with the MOTION performed over a DISTANCE s defined as $W = \vec{F} \cdot \vec{s} = Fd \cos \theta$, or in integral form: $W = \int \vec{F} \cdot d\vec{r} = \int F \cos \theta dr$. For rotation, this becomes: $W = \tau \Delta \theta$, where τ is the applied torque, and θ the angle of revolution. In case the force applied varies over time or over sections (s_i), the work can be summarized as calculated in stages in which the force can be considered as a constant: $W = \lim_{\Delta s_i' \rightarrow 0} \sum_i \vec{F}_i \cdot \vec{s}_i'$. (Note: work done by SPRING or by GRAVITY is a classic example of a nonlinear force.) With respect to energy, the following can also be said: work done on an object is equal to the change in KINETIC ENERGY (KE) of this object: $W = KE_2 - KE_1$. Work that is independent of the path followed between the beginning and the end point is defined as the result of a conservative force. The work done can be mechanical ($W_M = P\Delta V + v\Delta P$, where P is the pressure of a system, and V the partial volume occupied by the changing medium); or the work can be electrical ($W_e = -nF_{\text{Far}}\Delta V_{\text{elec}}$, where n is the number of transferred charges, $F_{\text{Far}} = 96,485 \text{ C/mol}$ the FARADAY CONSTANT, and ΔV_{elec} the maximum difference in electrical potential achieved through the motion of the charges) (see Figure W.47).

Figure W.47 Graph representing work as the area under the curve of force against the time the force is applied.

Work function (ϕ_{elec} in electron volt: eV)

[atomic, biomedical, electronics, general, nuclear] ENERGY needed for an ELECTRON to free itself from a surface, such as in an ELECTRON TUBE, or a PHOTO CELL used in the detection of LIGHT or to generate ELECTRICITY (also see PHOTO-VOLTAIC and PHOTOELECTRIC EFFECT). The work function for sodium is $\phi_{\text{elec}}|_{\text{Na}} = 2.28 \text{ eV}$, for copper: $\phi_{\text{elec}}|_{\text{Cu}} = 4.70 \text{ eV}$, whereas the work function for platinum is $\phi_{\text{elec}}|_{\text{Pt}} = 6.35 \text{ eV}$.

Work–energy theorem

[general, mechanics] The work (W) performed by a system equals the change in KINETIC ENERGY (KE) of that system: $W = \Delta KE$. This principle indicates the general interest in change, not so much to total energy content of a system, which technically includes all atomic and molecular energy.

Worthington jet

[fluid dynamics] Cavitation flow resulting from the impact of a solid sphere with a free (LIQUID) surface. The height of the JET (H_j) is a function of the object size (sphere diameter: D_b), velocity of impact, and the medium the object is impacting with, specifically there is a difference between Newtonian and non-Newtonian liquids. For an infinitely wide and infinitely deep pool of liquid, infinite being a relative term, at least three times the dimensions of the drop height may be a good approximation to avoid boundary effects. Note that the Worthington jet can also be generated by an object dropping in a pool of sand or other granular media. The viscosity of the liquid medium will dramatically impact the final outcome as well. With all factors considered, the height of the jet is defined by the following conditions: $H_j/D_b = f(\rho_r^*, Re, Fr)$, where $\rho_r^* = \rho_b/\rho_m$ the RELATIVE DENSITY from the ball (b), to the medium (m), $Re = \rho_m v D_b / \eta_e$ the REYNOLDS NUMBER, with η_e the effective viscosity of the medium, v the impact velocity, and subsequently $Fr = v / \sqrt{g D_b}$ the Froude number, with g the GRAVITATIONAL ACCELERATION. The mechanism of a liquid droplet falling on a solid surface also generates a Worthington jet; however, the conditions are different from breaking a liquid surface. The recoil force in the latter case is provided by the SURFACE TENSION of the liquid (F_τ), and is a function of the Weber number. The Weber number for a spherical fluid is $We = \rho v^2 D_b / F_\tau$. For a small Weber number, the surface tension will dominate and create a noticeable rebound and Worthington jet formation, whereas for a large Weber number, the kinetic ENERGY will dominate, resulting in a break-up and dispersal. No conclusive definition of the height of the rebound of the drop can be provided due to the wide range of boundary conditions, and only the influences can be described. The complete analysis of the Worthington jet falls under computational FLUID DYNAMICS (see [Figure W.48](#)).

(a)

(b)

Figure W.48 (a,b) Worthington jet.

W-Particle

[nuclear] Product of the DECAY process for a NEUTRON, delivering a W-particle and a PROTON; the “W” represents “weak,” for WEAK INTERACTION under the GAUGE THEORY. The W-particle is a VECTOR BOSON. All vector bosons are W^+ , W^- , and Z^0 . The mass for the W-vector bosons is $81 \text{ GeV}/c^2$, with $c = 2.99792458 \times 10^8 \text{ m/s}$ the speed of LIGHT. W-particles are highly unstable (decay time $\tau_d = 10^{-24} \text{ s}$) and decay into an electron–electron-antineutrino pair. The W-particle was introduced in 1956 by the theoretical physicist from the United States Julian Seymour Schwinger (1918–1994). Based on theoretical assumptions, the W-particle should be massless; however, due to the presence of the Higgs field, they acquire an ad-hoc spinless, SCALAR field, which provides the ENERGY to yield the REST MASS. In the theoretical description, the spin-0 Higgs bosons condense into a GROUND STATE that applies the classical field to the W-particles as well as the Z-particles, limiting their mobility to below light-speed interactions (see [Figure W.49](#)).

Figure W.49 W-boson (artist impression).

Wu, Chien-Shiung (Wú Jiànxíóng; 吳健雄) (1912–1997)

[atomic, nuclear] Scientist from mainland China. Dr. Wu was a collaborator on the MANHATTAN PROJECT. On an experimental approach, Chien-Shiung Wu illustrated that conservation of PARITY does not apply under NUCLEAR FISSION and NUCLEAR FUSION. Other efforts by Wu were in RADIOACTIVITY and the beta DECAY of isotopes under gaseous DIFFUSION (see [Figure W.50](#)).

Figure W.50 Chien-Shiung Wu (Wú Jiànxíóng; 吳健雄) (1912–1997), credit #2205. Wu, ChienShiungInLab. (Courtesy of University Archives, Columbia University in the City of New York, Photographer Manny Warman.)

X-ray

[biomedical, nuclear] Electromagnetic “Röntgen” RADIATION with wavelength between 0.01 and 10 nm. Quite frequently the term Röntgen radiation is found to describe this type of radiation to credit the German discoverer Wilhelm CONRAD RÖNTGEN (1845–1923), published in 1895. X-ray radiation is generated as a result of electron transitions (note that GAMMA RAY can be very similar, but its origin lies in the atomic NUCLEUS). X-ray radiation is a by-product of NUCLEAR FUSION or FISSION (ISOTOPE decay) and can be artificially generated by bombarding for instance a tungsten, rhenium, or molybdenum-alloy disk with fast electrons. The ANODE rotates to prevent localized overheating (cooling is a major requirement for the filament). The X-ray exposure during a medical exam results from exposure of a rotating anode in a Coolidge type tube with electrons from a fixed location CATHODE. The exposure to X-ray radiation falls under dosimetry and has strict limits to ensure prevention of biological damage. X-ray radiation exposure is quantified by gray ([Gy]) or rad ([rad]) as units of cumulative exposure, or as equivalent dose with respect to the potential of generating IONIZATION, obtained by multiplication of the ABSORBED DOSE by a factor describing the type and ENERGY of the radiation in Sievert ([Sv], old unit [rem]). The gray is a unit for absorbed dose in joule per kilogram, named in honor of the British originator of radiation control and his attempts to limit biological (i.e., genetic) and burn damage, Louis Harold Gray (1905–1965); proposed in 1940, defined in 1975. Exposure in excess of 100 Gy will result in an eventual, but unavoidable, death. Locally applied dosage in the order of 50 Gy is standard in RADIATION THERAPY, whereas a computed TOMOGRAPHY scan requires exposure in the order of 5 mGy and flying at 30,000 ft (~10 km) altitude is not significantly higher than the solar X-ray exposure obtained down on the EARTH during a picnic. The rad has primarily a historic value, defined in 1953 and $1 \text{ rad} = 0.01 \text{ Gy}$; sometimes used as a equivalent to the sporadic and mainly colloquial röntgen unit. The radiation weight factor (W_R) is as follows to obtain the equivalent dose: X-ray, gamma, beta, and muons $W_R = 1$; protons $W_R = 2 - 5$; NEUTRON radiation $W_R = 5 - 20$ depending on the energy; and for ALPHA PARTICLES and heavy nuclei, PARTICULARLY those produced under NUCLEAR FISSION, $W_R = 20$. The discovery of X-ray fueled the research into RADIOACTIVITY and FLUORESCENCE. Additionally, X-ray is used for a three-dimensional inspection on a diffraction level for atomic structure and for attenuation based on the density applied to nondestructive testing, airport human body scanners, and medical inspection as well as treatment options. Computed tomography (CT- or CAT SCAN) uses X-ray radiation from a multitude of directions arranged in a circumferential array or by a moving source with fixed scintillation counters or

photomultiplier tubes as the detection mechanism. The CT scan applies the line-of-flight principle to reconstruct a three-dimensional IMAGE from intersect points at the lines of attenuation in transmittance (see Figure X.1).

Figure X.1 (a) X-ray generation and (b) X-ray spectrum.

X-ray, characteristic

[atomic, nuclear] The RADIATION emitted resulting from ENERGY transitions in the inner bands of the BOHR ATOMIC MODEL, associated with a high-energy level electron BINDING ENERGY. Generally the narrow line-width characteristic radiation is superimposed on the broad-band BREMSSTRAHLUNG spectrum (BREMSSTRAHLUNG). For the VALENCE electrons, the EMISSION SPECTRUM is defined by the ENERGY transitions in the outer bands. The electron orbits are defined in the Bohr atomic model, described by NIELS HENRIK DAVID BOHR (1885–1962). The change in ENERGY LEVEL in the outer bands of the atomic model generates photons with frequency ν expressed by $h\nu = E_i - E_f$, where $h = 4.1356692 \times 10^{-15}$ J s is the Planck constant. In the inner electron bands, the energy levels are much greater and so are the energy QUANTA involved in the transitions. The wavelength (λ) of the emitted PHOTON is now proportional to the ATOMIC NUMBER (Z) of the material and the difference in the electron orbit from the inner orbit outward, with the inner orbit indicated by the condition $n = 1$, where n identifies the lower orbit with the highest energy and is defined as $1/\lambda = R_{\text{Ry}} (Z - 1)^2 \left[(1/(n^2)) - (1/(n + m)^2) \right]$, with $n \geq 1$ and $m \geq 0$ and $R_{\text{Ry}} = 1.097373 \times 10^7 \text{ m}^{-1}$ the RYDBERG CONSTANT. The associated frequency is $\nu = c/\lambda$, with c the speed of LIGHT. Hence there are grouping of emission lines that result from electron transitions ending at the same orbital level but starting from one or more levels of separation. The emission lines were classified by CHARLES GLOVER BARKLA (1877–1944) in 1911 as K -lines, L -lines, M -lines, and N -lines, respectively: $K_\alpha, K_\beta, K_\gamma, K_\delta, L_\alpha, L_\beta, L_\gamma, L_\delta, M_\alpha, M_\beta, M_\gamma, M_\delta, N_\alpha, N_\beta, N_\gamma, N_\delta$, with each successive alphabetical indicator (capitalized Roman letter) indicating the lower level (K for $n = 1$), with alphabetical subscript (Greek) indicating an increment in the value m , or a larger QUANTUM JUMP. This holds due to the fact that the lower level (e.g., $n = 1$) has under normal equilibrium conditions two electrons, but will have one electron missing because of excitation. Concurrently the net NUCLEAR CHARGE will be reduced resulting in the equivalent COULOMB FORCE proportional to $+e(Z - 1)$ (according to GAUSS'S LAW), not $+e \cdot (Z)$ (see CHARACTERISTIC X-RAY) (see Figure X.2).

Molybdenum (Mo) target impacted by electrons accelerated from a potential difference of 35 kV potential

Figure X.2 Characteristic X-ray radiation.

X-rays diffraction in crystals

[atomic] The use of X-RAY radiation for crystal LATTICE analysis, crystallography (see the VON LAUE METHOD) (see Figure X.3).

Figure X.3 (a–c) X-ray diffraction.

(Continued)

Figure X.3 (Continued) (a–c) X-ray diffraction.

XY model

[computational, thermodynamics] Special case for the situation $n = 2$ with regard to the n -vector lattice model pertaining to classical MECHANICS in a multidimensional setting. The D -dimensional lattice model (Λ) is defined by sites (i) , each occupied by a SPIN or rotator vector (spin configuration) $\vec{s} = (\vec{s}_i)_{i \in \Lambda}$, $\vec{s}_i = (\cos \theta_i, \sin \theta_i)$, which have orthogonal $O(2)$ symmetry (rotation around a fixed point) and $U(1)$ symmetry (GAUGE SYMMETRY, pertaining to the electromagnetic force). The XY model describes the PROBABILITY distribution for magnetization configuration of a medium that can be magnetized, for instance SUPERFLUID helium and certain LIQUID crystals, generally possessing a certain symmetry. The XY model contains the conditions for PHASE transitions within the system. In statistical mechanics, the probability $(P(\mathbb{S}))$ that a system possesses a certain state $(\mathbb{S})$ while at a certain TEMPERATURE (T) with ENERGY $E = \sum_{(i,j)} \vec{s}_i \cdot \vec{s}_j$ is described as $P(\mathbb{S}) = e^{-[E(\mathbb{S})/k_b T]} / Z_\ell(1/k_b T)$, where $k_b = 1.3806488 \times 10^{-23} \text{ m}^2 \text{ kg/s}^2 \text{ K}$ the Boltzmann coefficient, and $Z_\ell(1/k_b T) = \sum_{\mathbb{S}} e^{-[E(\mathbb{S})/k_b T]}$ the linearized portion of the PARTITION FUNCTION that is tied to the free energy $G_\ell(1/k_b T) = (1/\ell^D) \ln Z_\ell(1/k_b T)$, with D the dimension of the system (i.e., the DEGREES OF FREEDOM). Also known as the classical rotor model or the classical rotator model.

Yang, Chen Ning (清华大学) (1922–)

[computational] Physicist from China. Chen Ning Yang received the Nobel Prize in Physics in 1957 for his work on the PARITY OF ELEMENTARY PARTICLES, which he shared with Tsung-Dao Lee (李政道: 1926–) (see [Figure Y.1](#)).

Figure Y.1 Chen Ning Yang (清华大学) (1922–).

Yang–Mills field

[computational] The field that rules the Yang–Mills theoretical approximation. This QUANTUM field is based on PERTURBATION THEORY (developed in a series with units p), which can be solved only once the perturbation function ($\beta(\alpha_s)$; $\alpha_s = g_s^2/4\pi$ the coupling of the vector potential with g_s the gauge coupling constant that is indicative of the strength of the interaction) is known. The ENERGY field is a running coupling-based approach: $\mu_p^2(d\alpha_s/d\mu_p^2) = \beta(\alpha_s)$, μ_p the perturbation series components ($\mu_{p=0}$ providing the exact SOLUTION for the initial conditions). In this the perturbation at short wavelengths can be written as $\beta(\alpha_s) = -(11N/12\pi)\alpha_s^2 + (17N^2/24\pi^2)\alpha_s^3 + R(\alpha_s^4)$, where $R(\alpha_s^4)$ is a rest term (error term) and N represents the GAUGE SYMMETRY group rank, defining the number of gauge fields (e.g., photons,

weak bosons, strong bosons, and gluons); however, the long wavelength limit is not well defined (INFRARED limit) (see Figure Y.2).

Figure Y.2 Yang–Mills field. “U”—Up quark; “D”—Down quark.

Yang–Mills theory

[computational] Theoretical description of the elementary forces (the GAUGE THEORY) between protons and neutrons introduced by CHEN NING YANG (1922–) and Robert Laurence Mills (1927–1999), published in 1954. The Yang–Mills theory is a typical example of the gauge theory applied to the interaction of a weak current from a LEPTON interacting with a charged strong VECTOR BOSON.

Yield length

[general, mechanics] Stretch length applied before failure occurs (see Figure Y.3).

Figure Y.3 Yield length.

Yield stress (τ^*)

[fluid dynamics, mechanics] The applied stress threshold to transform a pseudoplastic or dilatant system into a homogeneous flow. $\tau^* = K_y(\epsilon - \epsilon_{\min})^2$, where K_y is a constant that depends on the colloid solution PARTICLE size and shape (e.g., sphere, rod, ellipsoid, and the respective aspect ratio of the sizes), $[\epsilon]$ the

concentration of constituent “ ϵ ,” with threshold minimum concentration $[\epsilon_{\min}]$. This applies to a tube flow, but also to stirrer interaction (see Figure Y.4).

Figure Y.4 Yield stress.

Young, Thomas (1773–1829)

[mechanics, optics] English physician and physicist. Young provided experimental proof in 1801 that electromagnetic RADIATION has a WAVE characteristic next to the PARTICLE identity shown with Snell’s experiments and theoretical description of REFLECTION and refraction. The wave characteristics were elucidated from the double slit INTERFERENCE pattern with a single source, resembling the node, crest, and trough pattern produced by water waves (see Figure Y.5).

Figure Y.5 Thomas Young (1773–1829). (Courtesy of The Royal Institution, UK, originally painted by Thomas Lawrence; copied either by Hugh Goldwin Riviere or Mabel Beatrice Messer.)

Young–Laplace equation

[biomedical, chemical, fluid dynamics, mechanics, thermodynamics] Nonlinear partial differential equation that is used to define the CAPILLARY pressure gradient across an equilibrium interface between two immiscible fluids, both stationary. The name is based on the experimental work of the English scientist THOMAS YOUNG (1773–1829) in 1805, describing SURFACE TENSION with the assistance of the French mathematician PIERRE-SIMON DE LAPLACE (1749–1827) in the mathematical formulation in 1806. The force balance between the pressure (P) and the surface tension (F_τ) at the surface S with circumference C is defined as $\int_S (P_1 - P_2) \vec{n} dS = -F_\tau \oint_C \vec{t} \times \vec{n} d\vec{r}$, where $\vec{t}$ is the tangent at the curve of the enclosure of the surface and $\vec{n}$ the normal to the surface, pointing in the direction from fluid 1 to fluid 2. Viscous forces are not applicable since the situation is stationary. This reduces to $(P_1 - P_2) = \Delta P = F_\tau \nabla \cdot \vec{n}$, where $\nabla = \sum_i \partial / \partial x_i$ is the Laplace operator, yielding $\nabla \cdot \vec{n} = 0$ for a flat interface.

Young's modulus (Y_n)

[general, mechanics] Plotting STRESS (σ_n) versus STRAIN (ϵ_n) provides a graph of the ELASTICITY of a solid; the linear section of the curve can be represented by a line function with a slope, where n indicates the DEGREES OF FREEDOM (primarily: x, y, z , respectively 1, 2, 3). Also called elastic modulus or bulk modulus under specific boundary conditions. The Young's modulus is hence defined as the stress in longitudinal direction per unit strain where the transverse modes are not confined (i.e., ϵ_2 and ϵ_3 are allowed to change). The slope of the linear part of the stress–strain curve is defined as the Young's modulus (Y_n) of that material under stress: $\sigma_n = Y_n \epsilon_n$, as defined by HOOKE'S LAW of linear elasticity. Technically the value of the Young's modulus can be different for a material under tension or under compression, in which case both values will be listed in reference books such as the *CRC Handbook of Chemistry and Physics*. The Young's modulus is the linear counterpart of the BULK MODULUS. Multidimensionally (specifically cubically), the Young's modulus can be expressed by the elasticity:

$$\sigma_m = C_{mn} \begin{bmatrix} \epsilon_{00} & \cdots & \\ \vdots & \ddots & \vdots \\ & \cdots & \epsilon_{nn} \end{bmatrix},$$

using $C_{mn} = \partial \sigma_m / \partial \epsilon_n$, as $Y_{\text{cub}} = [(C_{11} - C_{12})(C_{11} + 2C_{12})] / [(C_{11} + C_{12})]$. (see Figure Y.6)

Figure Y.6 Young's modulus.

Young's slit experiment

[optics] In order to produce two apparently coherent sources (not truly coherent, but good enough for the day) THOMAS YOUNG (1773–1829) placed a LIGHT SOURCE behind a single slit, which in turn produced an expanding WAVEFRONT that illuminated two closely separated slits. The two slits in turn produced two relatively coherent sources that resulted in an INTERFERENCE pattern on a screen placed behind the two slits. This interference pattern produced in 1801 reaffirmed the original hypothesis that light is a WAVE. The Newtonian particle concept for light still prevailed until well into the twentieth century. The interference pattern resembles the pattern generated from waves in water with two “coherent” sources, generated in a similar fashion. The DISTANCE of the locations of maximum interference with respect to the central maximum is given in terms of wavelength, where a whole wavelength difference in path length produces a positive interference and half a wavelength extinguishes the light locally. The angular (θ) dependence for the maxima is given as $a \sin \theta_m = m\lambda$, where $m = 0, 1, 2, \dots$ indicates the order of the maximum and a is the separation distance between the two slits. The original experiment used WHITE LIGHT, which resulted in a more pronounced separation of colors at greater distance from the center, with a white central interference line. Using a laser will produce a well-defined intensity (brightness) pattern (see [Figure Y.7](#)).

Figure Y.7 Young's slit experiment.

Yrast line

[nuclear] In the nuclear structure there is interaction between ENERGY levels, including the Coriolis coupling between energy bands (remember the Schrödinger WAVE equations [QUANTUM MECHANICAL PROBABILITY] and the fact that every moving object has a wave associated; de Broglie). The yrast line connects the yrast states of the lowest energy in the nuclear structure for a given angular momentum (see Figure Y.8).

Figure Y.8 Yrast line. (Courtesy of Mark A. Riley, John D. Fox Accelerator lab, Florida State University, Tallahassee, FL and Witold Nazarewicz, Michigan State University, East Lansing, MI.)

Yrast region

[nuclear] In the nuclear structure, the ENERGY band just above the YRAST LINE is the yrast region. The yrast region consists of rotational energy levels that are correlated to the deformed GROUND STATE of the nuclei. The deformation is the result of perturbations and influences, including Coriolis forces, “beta vibrations”

(“breathing”) and “gamma vibrations.” In this model, the NUCLEUS has energy formats that are considered as fluids. For an IRROTATIONAL FLOW in a “spheroidal drop,” the energy levels will be lowest (see Figure Y.9).

Figure Y.9 Yrast region; representative under extreme cold conditions.

Yrast state

[nuclear] In the nuclear structure, there are ENERGY levels associated with WAVE MOTION and momentum. The yrast state represents the lowest energy in the nuclear structure for a given angular momentum (see Figure Y.10).

Figure Y.10 Yrast state.

Yukawa, Hideki (1907–1981)

[computational, energy, general, thermodynamics] Theoretical physicist from Japan. Hideki (also Hideky) Yukawa predicted the pi-meson (PION) in 1932 (also known as the Yukawa particle), which was experimentally verified in 1960 by the Brazilian scientist CÉSAR MANSUETO GIULIO LATTES (1924–2005). Hideki Yukawa's reasoning was that the strong interaction (hadron–hadron interaction) had to be mediated by the exchange of a virtual BOSON of relatively a large size (quantum-mechanically spoken, based on energy–mass equivalence), the virtual meson pi. The pi meson is a QUARK—antiquark composite PARTICLE. Hideki Yukawa received the Nobel Prize in Physics in the year 1949 (see [Figure Y.11](#)).

Figure Y.11 Hideki Yukawa (1907–1981). (Courtesy of Amon Carter Museum of American Art, Forth Worth, TX.)

Yukawa potential

[computational, energy, general, thermodynamics] For the atomic NUCLEUS the nuclear forces can be described as suspended in a POTENTIAL WELL, defined by HIDEKI YUKAWA (1907–1981) in 1932. The Yukawa potential describes the one-pion exchange potential, based on the transfer of one MESON from one NUCLEON to another, where the interaction potential energy (U_p) between the nucleons separated at a DISTANCE r with the respective strength g_* is defined as $U_p = -g_*^2 (e^{-\mu_m r} / r) \cong Q / 4\pi r$, where $\mu_m = mc / \hbar$ (an operator in the

SCHRÖDINGER EQUATION), with m the REST MASS, $c = 2.99792458 \times 10^8$ m/s the speed of LIGHT, Q the collective charge, and $\hbar = h/2\pi$, with $h = 6.62606957 \times 10^{-34}$ m²kg/s the PLANCK'S CONSTANT (see Figure Y.12).

Figure Y.12 (a) Yukawa potential and (b) scattering cross section under the Yukawa potential.

Z

Z Boson

[general] Product of the DECAY process for a NEUTRON, delivering a Z-particle and a PROTON; subject to WEAK interaction under the GAUGE THEORY. The Z-particle is a neutral VECTOR BOSON. All vector bosons are W^+ , W^- , and Z^0 . The mass for the Z-vector bosons is slightly more than the W-boson, $91 \text{ GeV}/c^2$, with $c = 2.99792458 \times 10^8 \text{ m/s}$ the speed of LIGHT. Z-particles are subject to the Yang–Mills GAUGE FIELD interaction and are highly unstable (decay time $\tau_d = 10^{-24} \text{ s}$) and decay into an electron–electron-antineutrino pair. The Z-particle was introduced in 1961 by SHELDON LEE GLASHOW (1932–), a pupil of the theoretical physicist from the United States Julian Schwinger (1918–1994) (Nobel Laureate [1965]), known for his discovery of the charged W-bosons a few years earlier. Glashow received a Nobel Prize for his work on his discovery of the fourth QUARK, the CHARM quark, and other elementary PARTICLE work, specifically the GRAND UNIFIED THEORY applied to the WEAK FORCE and electromagnetic interaction in 1979, along with STEVEN WEINBERG (1932–) and Abdus Salam (1926–1996) (also see **W-PARTICLE**) (see [Figure Z.1](#)).

Figure Z.1 Representation of the concept of the Z-boson.

Zartman, Ira Forry (1899–1981)

[atomic, nuclear] Scientist from the United States who provided a detailed description of NEUTRON source FISSION processes. Ira Zartman also provided a theoretical description of the NUCLEAR FISSION process (see [Figure Z.2](#)).

Figure Z.2 Ira Forry Zartman (1899–1981).

Zeeman, Pieter (1865–1943)

[atomic, general, nuclear] Physicist from the Netherlands. The work of Pieter Zeeman illustrated the influence of an external MAGNETIC FIELD on the ATOMIC EMISSION lines of excited ELEMENTS, described under the ZEEMAN EFFECT. Zeeman had access to a power MAGNET and a fine DIFFRACTION GRATING, and experimented with the spectral emissions from a sodium flame (see [Figure Z.3](#)).

Figure Z.3 Pieter Zeeman (1865–1943).

Zeeman and Stark effect

[atomic, general, nuclear] ENERGY split in atomic electron transitions based on influences from magnetic fields modified by JOHANNES STARK (1874–1957) in 1913 based on the work of PIETER ZEEMAN (1865–1943) in 1896 (see ZEEMAN EFFECT and STARK EFFECT).

Zeeman effect

[atomic, computational, general, nuclear, quantum] ENERGY split in atomic electron transitions based on influences from magnetic fields. Introduced by PIETER ZEEMAN (1865–1943) in 1896. With several similarities to the STARK EFFECT (1913), this phenomenon is also known as the Zeeman–Stark effect, where the German scientist JOHANNES STARK (1874–1957) used an external electric field. When sending the emissions of the sodium LIGHT SOURCE through a DIFFRACTION GRATING under the exposure of an external steady-state MAGNETIC FIELD the D-line of the sodium emission was found to be split in constituent components. When an excited atomic state is exposed to an external magnetic field, the emission lines with respect to the unperturbed SOLUTION reveal a split that is associated with the ORBITAL ANGULAR MOMENTUM of the respective electron as well as the respective ELECTRON SPIN. This is different than the LAMB SHIFT. The phenomenon is dominated by the QUANTUM mechanical definition of ATOMIC ENERGY states. According to PETER DEBYE (1884–1966) and ARNOLD SOMMERFELD (1868–1951), the splitting of the spectral lines was associated with the orbital MAGNETIC QUANTUM NUMBER. The orbital “MAGNETIC” quantum number (m_ℓ) under the influence of an external magnetic field can assume values that are derived from the orbital ANGULAR MOMENTUM QUANTUM NUMBER (ℓ) ranging from $m_\ell = -\ell, (-\ell+1), \dots, (\ell-1), \ell$, hence splitting the field-free emission line for ℓ into a range of closely spaced lines associated with the orbital quantum number m_ℓ , using the quantization of the magnetic field in the z -direction (the axis of precision) as $L_z = m_\ell \hbar = m_\ell (h/2\pi)$, with $h = 6.6261 \times 10^{-34}$ J s the PLANCK’S CONSTANT; note that the orbital angular momentum quantum number (ℓ) is limited by the PRINCIPAL QUANTUM NUMBER (n ; $n: 1, 2, 3, \dots$). The energy difference (ΔE) between the states with different ORBITAL MAGNETIC MOMENT under the influence of the small perturbation provided by the applied magnetic field yields the following split: $\Delta E = g_L \mu_B m B = (\langle \mu_{Lz} \rangle + \langle \mu_{Sz} \rangle) B$, with $g_L = 1 + [J(J+1) + S(S+1) - L(L+1)]/2J(J+1)$ the Landé’s factor, J the TOTAL ANGULAR MOMENTUM, indicated by the QUANTUM NUMBER j , S the spin angular momentum (with quantum number m_s), and L the total orbital angular momentum, with the EIGENVALUE $L = \ell(\ell+1)\hbar^2$; $\mu_B = e\hbar/2m_e$ the Bohr magneton, with m_e the electron mass; m the quantum number of the z -component of the magnetic moment and B the MAGNITUDE of the external magnetic field and $\langle \mu_{Lz} \rangle$, respectively $\langle \mu_{Sz} \rangle$, the z -components of the average respective magnetic moments. The magnetic moments are $\mu_{Lz} = (e/2m_e)\sqrt{L(L+1)}\hbar \cos\theta_L \cos\theta$ and $\mu_{Sz} = (e/2m_e)\sqrt{S(S+1)}\hbar \cos\theta_S \cos\theta$, with $\theta = m_J/\sqrt{J(J+1)}$ and θ_L the ANGLE of the total orbital angular momentum with the total angular momentum and θ_S the angle of the SPIN angular momentum with the total angular momentum. The energy splitting between states depends on the quantum numbers for the respective states. In a transition between two singlet states, the spin angular momentum will be zero for both and the three remaining conditions are $m_J = -1; 0; +1$, which is considered the NORMAL ZEEMAN EFFECT. Under the condition that $S \neq 0$, L can change in accordance with the selection rules (nuclear and atomic transition selection rules: $n > l$; $j = \ell \pm (1/2)$; $m_\ell: 0, \pm 1, \pm 2, \dots, \pm \ell$; $m_j: -j, -j+1, \dots, 0, \dots, j-1, j$; $m_s = \pm(1/2)$), which contribute to

changes in g_L , providing a convoluted energy configuration and these transitions are referred to as the ANOMALOUS ZEEMAN EFFECT (*also see* PAULI EXCLUSION PRINCIPLE *and* FINE STRUCTURE) (see Figure Z.4).

Figure Z.4 Zeeman effect.

Zehnder, Ludwig (1854–1949)

[optics] Optical physicist from Switzerland. Best known for the development of the Mach–Zehnder INTERFEROMETER in collaboration with ERNST MACH (1838–1916) (see Figure Z.5).

Figure Z.5 Ludwig Zehnder (1854–1949).

Zeiss, Carl (1816–1888)

[optics] Scientist and entrepreneur from Germany. In 1840, Carl Zeiss started a corporation building optical devices that had set the standard for most optical technology offered, initially starting out with the fabrication of high quality lenses. The corporation was located in the city of Jena, which has an excellent resource for components to produce quality glass. The market switched from large APERTURE microscope lenses to CAMERA lenses as the popularity of the camera increased. In 1872, ERNST ABBE (1840–1905) joined the group. Abbe used the WAVE properties of LIGHT to increase the accuracy of LENS design, specifically with respect to RESOLUTION (*also see* ABBE CONDITION). The GLASS quality was further improved through the contributions of the material expert Otto Schott (1851–1935) in 1885 (see [Figure Z.6](#)).

Figure Z.6 Carl Zeiss (1816–1888). (Courtesy of Carl Zeiss Archives, Carl Zeiss Microscopy GmbH, Jena, Germany.)

Zenith

[astrophysics/astronomy, computational, geophysics] “Straight above.” The highest point reached by a celestial object in its orbit with respect to the observer’s frame of reference. Also used to define the moment in time when an observation or a phenomenon is most likely to occur (see [Figure Z.7](#)).

Figure Z.7 Zenith. (a) Angular definition and (b) influence of zenith angle position of the Moon on the tidal force vector.

Zenith angle

[astrophysics/astronomy, computational, geophysics] Angle elapsing directly overhead, in spherical coordinates designated as φ , alternatively: ϕ . The angle with respect to the horizon measured in the vertical direction. In comparison, the azimuth angle is measured in the “horizontal” plane. The zenith angle is frequently used to describe the solar angle; specifically with respect to the seasons (see Figure Z.8).

Figure Z.8 Zenith angle.

Zero-entropy state

[thermodynamics] In a diagram or graphical representation of the entropy states of a system as a function of boundary conditions, the state with the lowest entropy is referred to as the zero-entropy state. From a thermodynamic standpoint, there are no lower states, which makes the GROUND STATE zero plausible. Classical MECHANICS can often be considered a special case of THERMODYNAMICS: zero-entropy PHYSICS (see Figure Z.9).

Figure Z.9 Graphical representation of the Zero-entropy state; keeping in mind that the third law of thermodynamics “predicts” that for a crystalline substance at $T = 0\text{K}$, the entropy will as per the definition be equal to zero ($S = 0$). Diagram of the entropy for a system with four particles composed of two energy levels, described as a function of the total energy. The entropy is zero when all the particles are in either the lowest energy state or the highest state, whereas the entropy has a maximum value when the energies are split 50/50.

Zero-equation model

[computational, fluid dynamics] In computational FLUID DYNAMICS, the special case of turbulent models that can be addressed by algebraic equations only are considered zero-equation TURBULENCE models. The conditions and circumstances can be derived directly from the supplied parameters. As such, these models may not be able to account for the history of a process nor account for DIFFUSION or convection phenomena. The primary zero-equation model is for steady-state boundary layers, the simple viscous model, which requires no integration or differentiation. Two well-known zero-equation models are the “Baldwin–Lomax” model and the “Cebeci–Smith” model. The Baldwin–Lomax model provides the eddy viscosity for a two-layer system as a function of the local BOUNDARY LAYER velocity profile. The process separates the layer in an inner and an outer layer, where the inner layer has a fixed viscosity defined by Prandtl, and the outer region has a different constant value primarily derived from force equilibrium states. In the Cebeci–Smith model the viscosity is also derived from the velocity profile; however, in this case, it uses the averaged kinetic profile for the inner layer (using the first-order derivative for location as velocity) with pressure gradient, whereas the outer region makes an approximation by introducing a “velocity thickness” as a virtual constant layer.

Zero-G

[general] Hypothetical effective weightlessness. Obtained in the apparent or true absence of gravitational attraction. An airplane in free fall will create a condition of zero GRAVITY on the internal frame of reference. In reality, there are always gravitational forces acting, no MATTER how small, from distant planets, stars, and galaxies, or just another HUMAN BODY or SATELLITE. Even galaxies provide gravitational attraction on each other, forming complex and contorted “pin wheel” constructions ranging over thousands of light-years; there are several sets of three or more galaxies that have been imaged as a “set” (see [Figure Z.10](#)).

Figure Z.10 Zero-G; weightlessness: ultimate zero-G in the outer space.

Zero-mass particles

[general, quantum] Particles with zero mass can theoretically only exist at the speed of LIGHT. Examples of zero-mass particles are photons and neutrinos as well as gravitons. The GRAVITON is the theoretical PARTICLE mediating the gravitational interaction in an orbit around the objects between which the gravitational attraction is experienced. In this hypothetical case, the (quantum mechanical) graviton forms an ENERGY field rather than just an existence of mass. The graviton model resembles the chemical attraction in a MOLECULE that shares one or MOLE electrons. The zero-mass follows from the “rest energy,” which equals the momentum multiplied by the speed of light.

Zero-point energy

[atomic, nuclear] The lowest ENERGY of a system under QUANTUM mechanical conditions. Under the UNCERTAINTY PRINCIPLE, even a single particle out by itself in the outer space does not have zero kinetic energy; based on the definitions of the uncertainty principle, the PARTICLE will have zero-point energy. Alternatively, at the ABSOLUTE ZERO temperature, 0.000000000000000 K, theoretically there will be no MOTION and hence no discernable energy content, although the particle does exist and hence it has (quantum-mechanical) probabilities associated with it, as well as motion of the nuclei and orbiting electrons. The latter makes the case purely theoretical, with no physical means of achieving the true absolute zero Kelvin. Under zero-point energy conditions, electromagnetic RADIATION is still allowed. This ELECTROMAGNETIC ENERGY density can reach excessive values, theoretically up to 10^{58} J/m^3 (see Figure Z.11).

Figure Z.11 Zero-point energy.

Zero-temperature state

[thermodynamics] Ground ENERGY state for the constituents of the system, within a volume, which by definition has entropy zero and temperature zero. In physical terms, a temperature of ABSOLUTE ZERO Kelvin would mean that all MOTION has stopped and there is no energy in the system; all electron and nuclear motions would have come to a complete but hypothetical halt.

Zeroth law of thermodynamics

[general, thermodynamics] Concept introduced by JOSEPH BLACK (1728–1799) around 1760. The concept entails that when two materials of unequal temperature are brought in contact with each other they will both gradually reach a uniform equilibrium temperature (see THERMODYNAMICS, ZEROTH LAW).

Zhukovsky, Nikolay Yegorovich (also: Joukowsky; Николай Егорович Жуковский) (1847–1921)

[computational, fluid dynamics] Scientist and mathematician from Russia. Nikolay Zhukovsky contributed to the mathematical description of aerodynamic LIFT pertaining to flight. His work led to the implementation of the rounded frontal tip on a WING based on his theoretical analysis as well as the sharp tip on the rear to create a flow that exits without TURBULENCE. He also established the first aerodynamic institute near Moscow.

His other work includes the WATER–HAMMER equation, which is also known as the JOUKOWSKY EQUATION (see [Figure Z.12](#)).

Figure Z.12 Nikolay Yegorovich Zhukovsky (also: Joukowski; Николая Егорович Жуковский) (1847–1921) in 1915.

Zweig, George (1937–)

[energy, general, quantum, relativistic] Physicist from the Russian Federation (USSR; Union of Soviet Socialist Republics. Russian СССР Союз Советских Социалистических Республик, English translation: Soyuz Sovetskikh Sotsialisticheskikh Respublik). George Zweig along with MURRAY GELL-MANN (1929–), provided evidence that baryons (as well as the other HADRON group: mesons) are not primary ELEMENTARY PARTICLES. Dr. Zweig was a pupil of RICHARD FEYNMAN (1918–1988) (see [Figure Z.13](#)).

Figure Z.13 George Zweig (1937–). (Courtesy of CERN, Centre Européenne pour la Recherche Nucléaire, European Organization for Nuclear Research, Zurich, Switzerland.)

Appendix A

Common physical constants

Avogadro's number: $N_A = 6.022140857(74) \times 10^{23} \text{ mol}^{-1}$

Boltzmann coefficient: $k_b = 1.38064852(79) \times 10^{-23} \text{ m}^2 \text{ kg} / \text{s}^2 \text{ K}$

Coulomb's constant: $k_C = (1/4\pi\epsilon_0)$, where: $\epsilon_0 = 8.854187817... \times 10^{-12} \text{ C}^2 / \text{Nm}^2$ the permittivity of free space

Electron charge: $k_e = 8.987551787... \times 10^9 \text{ Nm}^2 / \text{C}^2$

Electron Compton wavelength: $\lambda_C = 2.426312367(11) \times 10^{-12} \text{ m}$

Electron mass: $m_e = 9.10938356(11) \times 10^{-31} \text{ kg}$

Faraday constant: $F = 96485.3365 \text{ sA/mol} = 9.648533289(59) \times 10^4 \text{ C/mol}$

Gas constant: $R = 8.3144621(75) \text{ J/Kmol}$

Gravitation constant: $G = 6.67408(31) \times 10^{-11} \text{ Nm}^2 / \text{kg}^2 = 6.67408(31) \times 10^{-11} \text{ m}^3 / \text{kg s}^2$

Permeability of free space: $\mu_{E0} = 1.2566370614... \times 10^{-6} \text{ H/m}$

Permittivity of free space: $\epsilon_{EM0} = 8.854187817... \times 10^{-12} \text{ C}^2 / \text{Nm}^2$

Planck's constant: $h = 6.626070040(81) \times 10^{-34} \text{ m}^2 \text{ kg/s}$, $\hbar = (h/2\pi)$

Proton mass: $m_p = 1.672621898(21) \times 10^{-27} \text{ kg}$

Rydberg constant: $R_y = \frac{2\pi^2 k_b^2 e^4 m_e Z^2}{h^3 c} = \frac{10973731.568508(65) \text{ m}^{-1}}{Z=1}$

Speed of light: $c = \sqrt{\mu_0 \epsilon_0}^{-1} = (\mu_0 \epsilon_0)^{-1/2} = 2.99792458 \times 10^8 \text{ m/s}$

Stefan-Boltzmann constant: $\sigma_{SB} = 5.670367(13) \times 10^{-8} \text{ W/m}^2 \text{ K}^4$

Heike Kamerlingh Onnes (1853–1926)
William Thomson, 1st Baron Kelvin (Lord Kelvin) (1824–1907)
Johannes Kepler (1571–1630)
Gustav Robert Kirchhoff (1824–1887)
Diederik Johannes Korteweg (1848–1941)
(Joseph Louis) Giuseppe Luigi comte de Lagrange (1737–1813)
Sir Horace Lamb (1849–1934)
Willis Eugene Lamb (1913–2008)
Johann Heinrich Lambert (1728–1777)
Adrien-Marie Legendre (1752–1833)
Pierre-Simon de Laplace (1749–1827)
Max Theodor Felix von Laue (1879–1960)
Antoine Laurent de Lavoisier (1743–1794)
Ernest Orlando Lawrence (1901–1958)
Sir John Edward Lennard-Jones (1894–1954)
Joseph Liouville (1809–1882)
Hans Lipperhey (1570–1619)
Aleksandr Mikhailovich Lyapunov (1857–1918)
Colin Maclaurin (1689–1746)
Hendrik Antoon Lorentz (1853–1928)
Ernst Mach (1838–1916)
Pierre Pelerin de Maricourt (AKA Peter Peregrine) (c. 1220–1270)
Ernest Marsden (1889–1970)
James Clerk Maxwell (1831–1879)
Maria Goeppert-Mayer (Göppert) (1906–1972)
Gustav Mie (1869–1957)
Dmitri Ivanovich Mendeleev (1834–1907)
Albert Abraham Michelson (1852–1931)
Robert Andrews Millikan (1868–1953)
Henry de Mondeville (1260–1320)
Earle Gordon Moore (1929–)
Edward Morley (1838–1923)
Henry Gwyn Jeffreys Moseley (1887–1915)
Henry Mosley (1887–1915)
Rudolf Ludwig Mössbauer (1929–2011)
Robert Sanderson Mulliken (1896–1986)

Edward Aloysius Murphy, Jr. (1918–1990)
 Pieter van Musschenbroek (1692–1761)
 Claude-Louis Navier (1785–1836)
 Walther Hermann Nernst (1864–1941)
 Thomas Newcomen (1664–1729)
 Sir Isaac Newton (1642–1727)
 Paul Gottlieb Nipkow (1833–1940)
 Harry Theodor Nyquist (“Nyqvist”) (1889–1976)
 Hans Christian Oersted (1777–1851)
 Georg Simon Ohm (1787–1854)
 Heike Kamerlingh Onnes (1853–1926)
 Robert J. Oppenheimer (1904–1967)
 Denis Papin (1647–1712)
 Blaise Pascal (1623–1662)
 Alexis Petit (1791–1820)
 Max Karl Ernst Ludwig Planck (1858–1947)
 Plato (427–347 BC)
 Jules Henry Poincaré (1854–1912)
 Jean-Louis Léonard Marie Poiseuille (1799–1869)
 Siméon Denis Poisson (1781–1840)
 Ludwig Prandtl (1875–1953)
 Claudius Ptolemaeus (also: Ptolemy) (approx. 90–168 AD)
 Ptolemy (c. 90–168 AD)
 Wolfgang Ernst Pauli (1900–1958)
 Oscar Raab (1876–1986)
 Isidor Isaac Rabi (1898–1988)
 Sir Chandrasekhara Venkata Raman (1888–1970)
 William John Macquorn Rankine (1820–1872)
 Rembrandt van Rijn (1606–1669)
 Olaus (Ole) Christensen Rømer (Roemer) (1644–1710)
 Ernest Rutherford (1871–1937)
 John William Strut, the 3rd Baron Rayleigh (1842–1919)
 Osborn (Osborne?) Reynolds (1842–1912)
 Wilhelm Conrad Röntgen (1845–1923)
 Count Rumford (1753–1814), Benjamin Thompson
 Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson
 Johannes Robert Rydberg (1854–1919)
 Wallace Clement Sabine (1868–1919)
 Joseph Sauveur (1653–1716)
 Félix Savart (1791–1841)
 Arthur Leonard Schawlow (1921–1999)
 Paul Scherrer (1890–1969)
 Sir Franz Arthur Friedrich Schuster (1851–1934)
 Thomas Savery (1650–1715)
 Erwin Schrödinger (1887–1961)
 Sir Franz Arthur Friedrich Schuster (1851–1934)
 Karl Schwarzschild (1873–1916)
 Thomas Johann Seebeck (1770–1831)
 Arnold Johannes Wilhelm Sommerfeld (1868–1951)
 Johannes Stark (1874–1957)
 Ernest Starling (1866–1927)
 Joseph Stefan (1835–1893)

Sir George Gabriel Stokes, 1st Baronet (1819–1903)
Jacques Charles François Sturm (1803–1855)
Brook Taylor (1685–1731)
Edward Teller (1908–2003)
Nikola Tesla (1856–1943)
Thales of Miletus (c. 624–c. 546 BC; known as Thales: Θαλῆς)
Joseph John Thomson (1856–1940)
Charles Hard Townes (1915–)
Evangelista Torricelli (1608–1647)
Rudolf Snel van Royen (Snellius) (1546–1613)
Willebrord Snel van Royen (Snellius) (1591–1626)
Robert Jemison van de Graaff (1902–1967)
Johannes Diderik van der Waals (1837–1923)
Jacobus Henricus van 't Hoff (1852–1911)
Urban le Verrier (1811–1877)
Andreas Vesalius (1515–1564)
Leonardo da Vinci (1452–1519)
John Hasbrouck Van Vleck (1899–1980)
Count Alessandro Giuseppe Antonio Anastasio Volta (1745–1827)
James Watt (1736–1819)
Sir Charles Wheatstone (1802–1875)
John Archibald Wheeler (1911–2008)
Thomas Young (1773–1829)
Carl Zeiss (1816–1888)

Appendix C

Acoustics

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
27,000 BC	Lin-Lun	Huang-Zhong pipe, “calibrated musical tone,” designed by Lin-Lun from bamboo under the reign of the Chinese Yellow Emperor Huangdi. The musical range of sound was further separated into 12 standard pitch pipes.
2,000 BC	Fohi	First documented attempt to correlate pitch and sounds produced by “the five elements: earth, water, fire, air, and wind.”
~500 BC		Greek empire scientific division of sounds into three tone “genders:” chromatic, diatonic, and enharmonic, very similar to the present day musical classification. This musical note organization was derived from Arab influences who based their knowledge on Hindu influences dating back several centuries.
~500 BC	Pythagoras (570 BC–497 BC)	Definition of a single note generated as the result of the air motion with the same “frequency” as the reverberating body. Pythagoras paved the way for the musical definition in octaves (double-frequency segmentation) with mathematical formulation. Pythagoras also derived that the “sharpness” of the tone produced by a reverberating string is inversely proportional to its length, that is, frequency (pitch).
~350 BC	Aristotle (384 BC–322 BC)	Description of the movement of air under the influence of a vibrating body.
240 BC	Chrysippus (279 BC–206 BC)	Forming an analogy to water waves, the Greek philosopher Chrysippus derived that the waves on the string of the lute form a sound wave propagating in air with similar patterns of perturbation.
25 BC	Marcus Vitruvius Pollio (ca. 80 BC–15 BC)	Description of the use of vases in the amphitheaters that will attenuate low frequency sound, similar to current day acoustic baffles used in architecture. First documented use of architectural acoustic design.
1500	Leonardo da Vinci (1452–1519)	Description of the requirements of a medium to transmit sound. Da Vinci also made the same correlation between water waves and sound waves as the Greek philosopher Chrysippus (near 2,000 years prior). Leonard da Vinci also derived that sound has a distinct velocity of propagation.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1636	Marin Mersenne (1588–1648)	First scientific description of the audible tone, specifically 84 Hz. Marin Mersenne also introduced the formal concept of the octave and measured the velocity of sound
1638	Galileo Galilei (1564–1642)	Publication of <i>Mathematical Discourses Concerning the New Sciences</i> providing a definition of sound and frequency similar to that of his contemporary Marin Mersenne, but apparently independently derived.
1640	Pierre Gassendi (1582–1655)	Argument that sound was a stream of “particles” (atoms) emitted from a body. This concept was not accepted and is not in line with observations and deductions made over the past millennia.
1650	Francesco Maria Grimaldi (1613–1663)	Correlation between light wave refraction and similar aspect of visible and audible (mechanical) waves.
1660	Robert Boyle (1626–1691) and assistant Robert Hooke (1635–1703)	Experimental verification of the Leonardo da Vinci’s argument for the requirement of a medium by means of an evacuated chamber with a ticking clock inside.
1678	Robert Hooke (1635–1703)	Mathematical representation of force and deformation, providing the fundamentals for vibration and elastic theory.
1700	Joseph Sauveur (1653–1713)	Introduction of the word “acoustics” derived from the Greek word for sound. Joseph Sauveur actually was a deaf–mute and provided significant contributions to the present day understanding of acoustic concepts. Sauveur introduced the concepts of fundamental wave, harmonics, node, next to ventral segment.
1816	René-Théophile-Hyacinthe Laennec (1781–1826)	Inventor of the stethoscope, using a wooden horn to amplify the sound originating from a beating heart. Note that the use of animal horns for the collection of weak sounds (spoken word) has been recorded centuries prior to the beginning of the western calendar (before Christ; BC, even millennia BC).
1836	Ernst Florence Friedrich Chladni (1756–1827)	Discovered torsional vibrations. His work advanced acoustical engineering and acoustical architecture.
1842	Christian Andreas Doppler (1803–1853)	Introduction of the “Doppler effect,” defining the change in perceived frequency of a wave (or other periodic event) for an observer and source moving relative to each other.
1845	Simon Ohm (1789–1854)	Introduction of the discrete concepts in hearing for the ear. Simon Ohm hypothesized that there are individual segments in the ear that respond to only a single sine wave frequency, the ear separates sound in its fundamental frequency and harmonics by mechanical means.
1847	James P. Joule (1818–1889)	Discovery of the magnetostrictive effect; paving the way for ultrasonic imaging.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1863	Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Foundations for spectral analysis of sound.
1877	Lord Rayleigh (1842–1919) [John William Strutt]	Theoretical publication on the physical aspects of acoustics; publication: <i>Theory of Sound</i> . Lord Rayleigh also introduced the mechanical (destructive) force associated with the cavitation aspect of sound. Cavitation would fall under fluid dynamics in the theoretical sense.
1880	Paul-Jacques Curie (1855–1941) and Pierre Curie (1859–1906)	Further evidence supporting the evolution of ultrasonic imaging with the discovery of electric charges emerging on the surfaces of certain crystals which are subjected to pressure or tension (shear or normal stress). This is referred to as the piezoelectric effect.
1900–1915	Wallace Clement Sabine (1868–1919)	Fundamental revisions to acoustical design. Established the Riverbank Acoustical Laboratories in Geneva, Illinois.
1910	Sir Horace Lamb (1849–1934)	Wave mechanics: Lamb wave. Theory of sound. Horace Lamb also contributed to hydrodynamic descriptions (1895).
1920–1930	Paul Earls Sabine (1879–1958) and son Hale Johnson Sabine (1909–1981)	Noise control and architectural acoustic design.
1937	Karl Theo (Theodore) Dussik (1908–1968)	Ultrasonic imaging.
1920–1940	Harvey Fletcher (1884–1990)	Introduction of quantifying the perception of sound and mechanical waves in the Bell Telephone Laboratories; referred to as “psychoacoustics.” Introduction of the loudness concept and the decibel as a quantity for sound magnitude. Harvey Fletcher also introduced the first electronic hearing aid device.
~1940	Harry F. Olson (1902–1982)	Loudspeaker design and definition for the reproduction of sound from electronic sources.
~1954	Georg von Békésy (1899–1972)	Fundamental description of the mechanism of action in human hearing.
1964	Warren P. Mason (1900–1986)	Revolutionized the concept of ultrasound imaging. Refinements to soft-tissue imaging and work on three-dimensional reconstruction. The combination of different transducers enhances the resolution and can yield additional material-specific information.

Astronomy

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
13.8 billion years BC	Georges Henri Joseph Édouard Lemaître (1894–1966) and Edwin Powell Hubble (1889–1953)	“The Big Bang,” in 1927 the expanding universe was recognized.
30,000 BC		Early human’s impression of the heavens, drawings of eclipses, comets, specifically the drawing of a supernova, such as the Pueblo Petrograph.
4,500 BC	Carnac Stones	Arrangement of menhirs depicting the solar system in a rudimentary fashion, specifically the sun and the moon positions.
3,100 BC	Stonehenge	Neolithic (preceding the Bronze Era) astronomical abacus used for calculating the positions of planets and the occurrence of the changes in the Sun with respect to Earth: solstice. Alleged connection with the Druids of King Arthur’s court.
ca. 2,800 BC		Mesopotamian astronomers use the moon as a guide for calendar development: lunar calendar. The Mesopotamian calendar has 354 days.
ca. 2,700 BC		Astronomers in Sumeria evolve the lunar calendar in a solar year.
1,600 BC	Babylonia	Recordings of planets, comets; the elliptical orbits time of transition, transcribed on clay tablets (this type of record keeping is referred to as cuneiform).
1,581 BC	King Ammizaduga of Nivevah (mid-eastern; Mesopotamia; stretching out into northern Africa, Europe, reaching out into Pakistan and Western Russia)	Description of scientific methodology used by the Babylonian astronomers. Detailed description of the orbital motion for the planet Venus.
~500 BC	Hellenistic culture	The ancient Greeks using astronomical records which they inherited from the Babylonians to generate a <i>cosmological framework</i> . Data was used for both practical goals, such as navigation, in addition to predicting future experiments. This may be interpreted as the introduction of the concept of the “natural philosopher.” The Greek word “astronomy” refers to “law and order.” The word expresses the attempts to seek order in the surroundings of the earth. The Greek combined the words: ἀστρονομία from ἄστρον astron, describing the concept of “star” and -νομία -nomia from νόμος nomos, meaning “law.”

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
~580 BC	Thales (c. 624 BC–546 BC)	Greek astronomer who used the Babylonian data to predict the recurrence and orbital trajectories of solar eclipses.
~355 BC	Plato (424 BC–348 BC)	
~350 BC	Aristotle (384 BC–322 BC)	Geocentric model for the solar system.
330 BC	Heraclides (387 BC–312 BC)	First recorded scientific model of the “solar system” as a geocentric configuration. This initiated the debate of the geocentric versus heliocentric configuration. The orbits of all the planets were considered perfect spheres based on the assumption that the universe was “perfect” and with little data available to prove otherwise.
270 BC	Aristarchus [of Samos] (310 BC–230 BC)	Introduction of the heliocentric model for the earth’s solar system.
220 BC	Eratosthenes (276 BC–194 BC)	The early Greeks derived that the Earth is a sphere based on the observed shadow of Earth on the Moon during lunar eclipses. Eratosthenes calculated the circumference of Earth (not using the mathematics outlined by Pythagoras (570 BC–495 BC)) using the length of the shadow in two location in Greece; at Syene the stick casts no shadow, while the shadow at the same time in Alexandria had a certain length. The value of the circumference derived by Eratosthenes of 40,320 km (252,000 stadia; 1 stadia = 0.16 km) while the current accepted circumference at the equator is 40,030 km.
150 BC	Hipparchus (190 BC–120 BC)	First recorded star catalog, including the names of constellations.
150 AD	Ptolemy (90–168)	Librarian of Alexandria who reintroduced the geocentric theory of Heraclides and formulated a complete description of the solar system that explained as well as predicted the apparent planetary motions using the combined data from centuries of observations on planetary motions. The mathematical model of Ptolemy was very complex and difficult to use to describe the elliptical orbits. The approximation used circles upon circles, requiring more than 28 circle combination to define the orbital patterns. The solution to retrograde motion explained the orbits of the planets by means of epicycles and deferents. The primary orbit is the deferent, the perturbation orbit is the epicycle.
ca. 1000	Mohammed ibn al-Hasan (Alhazen) ‘Abu Ali’ ibn al-Haytham al-Basra (965-1039) [Iraq, Egypt]	Mathematical descriptions in optics and astronomy. The work of Al Hazen anticipated Newton’s First Law of Motion {Sir Isaac Newton (1643–1727)}; the “principle of least action.”
1054	China	Crab Nebula is the remnant of a star that was observed to explode by Chinese astronomers. The Crab Nebula is located at a distance of 6,523 light years from earth.
5th century–15th century		Dark Ages; geocentric Ptolemy model.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
4th century–7th century		Renaissance.
1500	Nicolaus Copernicus (1473–1543)	Reintroduction of the heliocentric planetary model for earth. Challenging the doctrine of the Roman Catholic Church. Copernicus still used circular orbits.
1580	Tycho Brahe (1546–1601)	Construction of an observatory in Denmark. Tycho Brahe used a sextant and trigonometry to analyze the planetary orbits and derived their elliptical orbits. Telescopes were not available during his lifetime.
ca. 1600	Galileo Galilei (1564–1642)	Described laws of motion (falling bodies; gravitational acceleration) and inertia, before Sir Isaac Newton (1643–1727). Invented the pendulum clock and many more engineering feats. Additional contributions by Galileo Galilei are in astronomy, specifically the discovery of Jupiter's moons. Galileo also wrote about infinite equinumerosity, what is known as the “Hilbert's Hotel Paradox” (David Hilbert (1862–1943); “Hilbert Space”). Galileo once wrote “Mathematics is the language in which God has written the universe.”
1600	Johannes Kepler (1571–1630)	Refinements to the models introduced by his mentor Tycho Brahe on the elliptical orbits. Formulation of the “laws of planetary motion,” beginning of the conceptual introduction of the “clockwork universe.”
1603	Johann Bayer (1572–1625)	Introducing named stars for their constellation by Greek letters, in “Uranometria” in the approximate order of (apparent) radiance “brightness,” for example, Alpha Centauri.
1609		Introduction of the first telescope.
~1620	Galileo Galilei (1564–1642)	Introduction of laws of motion. Recorded observations of the universe with the first telescopes (refracting). Providing conclusive evidence for the heliocentric solar system, challenging the long-lasting geocentric solar system model. Galileo's observations led to the discovery that the sky filled with light is constructed of a multitude of stars, in our direct vicinity forming the Milky Way. He also discovered that the planet Jupiter has moons, the sun has “sun spots,” and that the moon has a surface profile that is not flat (valley's and mountains).
1661	Johann Hevelius (1611–1687)	Published “Sternverzeichniss,” the “meaning”/description of stars.
1666	Sir Isaac Newton (1643–1727)	Description of the spectral composition of the sunlight using a prism.
1679	Edmond Halley (1656–1742)	Publication of the first southern star catalog.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1680	Sir Isaac Newton (1643–1727)	Universal law of gravitation. Introduced the first reflecting telescope and formulated the theory of light.
1712	John Flamsteed (1646–1719)	<i>Historia Coelestis Britannica</i> , edited by Edmond Halley. This catalog introduces the Flamsteed Number, labeling stars (e.g., 21 Tauri).
1731	John Bevis (1693–1771)	Description of the Crab Nebula has been discovered near the star Z Tauri. John Bevis was at that time making his Stellar Atlas, which was published in the year 1786.
1750	Leonhard Euler (1707–1783)	Most prolific mathematician in the known history of mathematics. Euler developed the polyhedral theorem (with some suspicion that this may be traced back to René Descartes (1596–1650). Euler revolutionized the design of pumps based on his fluid dynamic theories, including turbine equations. Other theoretical interests of Leonhard Euler were optics, astronomy, acoustics, mechanics, and music. In his astrophysics work, he developed a formulation to determine the moon orbit in a three body motion problem; first ever. Additional theoretical efforts defined the rotational motion of rigid bodies of various configurations. Euler also introduced the definition for the square root of negative one as the letter “i”, next to several other mathematical standard expressions for algebraic terms. Leonard Euler also introduced the exponential expression with the use of the complex number by means of sin and cosine: $e^{ix} = \cos x + i \sin x$. Euler popularized the use of the letter Sigma for a series summation.
1781	Charles Messier (1730–1817)	Recording of the Crab Nebula in the Messier catalogue as Number 1. The total catalogue contained 103 entries.
1782	William Herschel (1738–1822)	Published catalogue of 2500 celestial objects, including 269 double stars.
1799	Pierre Simon, Marquis de Laplace (1749–1827)	Laplace Law; Laplace transform to solve complex equations and his work on celestial mechanics (astrophysics).
1818	Joseph Fraunhofer (1787–1826)	Description of the solar spectrum, recognizing 576 dark lines. The more prominent lines were labeled with letters A to K. He also discovered that the light reflecting from the Moon and planets displayed spectral features that were also in that of the solar spectrum; furthermore that the spectra of planets differ from the solar spectrum. Joseph Fraunhofer designed and used the diffraction grating, one of which had the astounding (for the time) 3,625 lines per centimeter.
1832	David Brewster (1781–1868)	Spectra of cold gases produce dark absorption lines in continuous spectra.
1841	John W. Draper (1811–1882)	First picture made of the Moon. Picture made by J. W. Draper on Daguerre plates.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1845	William Parsons (1800–1876)	Lord William Parsons, 3rd Earl of Rosse (1800–1876) discovers the spiral pattern of M51, and subsequently for the M99 nebulae classification (Messier scale) and 13 other “nebulae” which were since known as “spiral nebulae.”
1847	John W. Draper (1811–1882)	Discovery that hot solids emit light in continuous spectra, and in contrast, hot gases produce line spectra.
1857	Joseph von Fraunhofer (1787–1826) Carl August von Steinheil (1801–1870) William Lassell's (1799–1880)	Start of large size, high quality, reflector telescope construction and use. Telescope optics was notably improved by Joseph von Fraunhofer (1787–1826) with the development of the achromatic objective in 1824, this initiated the construction of larger refractor telescopes up to the Yerkes 102 cm. The reflector techniques followed significant improvement from the invention of glass mirrors by Carl August von Steinheil (1801–1870) in 1857 when constructing a 10 cm reflector, which was succeeded by the 33-cm reflector telescope developed by Michel Foucault (1926–1984), and the 60-cm glass mirrors of Lassell telescope named after William Lassell (1799–1880). Most big telescopes of the twentieth century are reflector telescopes made with glass mirrors. The first telescope exceeding Lord William Parsons, 3rd Earl of Rosse's (1800–1876) Leviathan of 1845, with 1.8 m opening, in aperture was the 2.54m diameter Mount Wilson telescope constructed 1917, followed by the Palomar telescope with diameter of 5.08 m in 1948, and the Zelenchukskaya telescope with diameter of 6.1 m in 1976, with only partial success unfortunately.
1852–1859	Friedrich Wilhelm Argelander (1799–1875)	Elaboration on the Messier catalog, containing the magnitude (radiance) and relative positions of 324,000 stars in the Bonner Durchmusterung. this is translated from German with liberal interpretation: the “Elaboration performed at Bonn”; the city Bonn in Germany (Die Rheinische Friedrich-Wilhelm-Universität Bonn) had instated a new observatory, designed by Friedrich Wilhelm Argelander.
1845–1890	Adalbert Krüger (1832–1896) and Eduard Schönfeld (1828–1891)	Collaborators. Introduction of the Star Catalogue: “Bonner Durchmusterung.” Comprehensive outline of the stellar configuration.
1859	Gustav Robert Kirchhoff (1824–1887) and Robert Bunsen (1811–1899)	Discovery that characteristic spectrum of lines are resulting from individual chemical element (and compound), where the lines are at the same respective wavelengths in emission spectra and alternatively absorption spectra. Hence the chemical composition of any light source, including celestial bodies (both stars and planets from which light is reflecting), can be resolved from spectral analysis. Robert Kirchhoff published the initial chemical constitution of the Sun in 1859.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1861	Karl Friedrich Zöllner (1834–1882)	Introduction of the to-date most accurate and quantifiable photometer used for classifying stellar object.
1863	Anders Jonas Ångström (1818–74)	Publication of the map of the Solar spectrum, identifying of lines corresponding chemical elements.
1864	John Herschel (1792–1871)	Published General Catalog of more than 5,000 nonstellar objects.
1864	William Huggins (1824–1910)	Discovery of gaseous nebulae spectra and found them to be emission line spectra. This observation provided as simple and unique criterion distinguishing the nebulae from star clusters. Star clusters, on the other hand, similar to the stars that composing, show a continuous spectrum (in which absorption and sometimes emission lines appear overlaid). Spiral “nebulae,” however, show continuous spectra similar to stars.
1868	William Huggins (1824–1910)	Based on the work by Christian Doppler (1803–1853) describing the shifting spectral lines with respect to moving bodies, outlined how this should effect the galactic spectroscopy and that spectral lines of moving celestial objects should appear shifted. The first measurements affirming this effect were obtained in 1888 by Hermann Carl Vogel (1841–1907).
1872	Henry Draper (1837–1882)	First spectral photograph of the star Vega.
1876	Father Angelo Secchi (1818–1878)	Spectroscopic classification of first classification of 316 stars.
1880	John Louis Emil Dreyer (1852–1926)	J. L. E. Dreyer’s New General Catalogue (NGC), building on the Messier Catalogue. The NGC lists over 13,0000 stellar and nonstellar objects.
1900	Cornelius Easton (1864–1929)	Description of the Milky Way as a spiral nebula, with the earth’s solar system at a distance of approximately 8000 pc (parsec; 1 pc $\approx$ 3.26 light-years) from its center.
1906	Karl Schwarzschild (1873–1916)	Model development and publication for the solar atmosphere from theory of thermodynamical equilibrium. Description of the equation of radiative transfer.
1907		Potsdamer Durchmusterung; star catalog compiled in Potsdam, Germany.
1904–1908	Karl Schwarzschild (1873–1916)	Göttinger Aktinometrie; theoretical description of the radiance with respect to galactic location, stellar energy, and angular perception.
1914–1924	Harvard Observatory	Henry Draper Catalogue, describing the spectral profiles of 225,300 stars; referring to Henry Draper (1837–1882), pioneering astrophotography and associated spectral analyses.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1924	Edwin Powell Hubble (1889–1983)	Definition of the outer part of the Andromeda “Nebula (M31)” consisting of stars and found novae and Cepheid variables, in this manner it was established to be an external galaxy or star system.
1926	Bertil Lindblad (1895–1965) and Jan Oort (1900–1992)	definition of the theory of kinematics and dynamics of the Milky Way galaxy.
1929	Edwin Powell Hubble (1889–1983)	Derivation of distance–red shift relation for galaxies. Theoretical description of the expansion of the universe.
1951		Discovery of the 21-cm radio radiation emerging from galactic neutral hydrogen, which provided further supporting evidence for the spiral shape of the Milky Way.
1963	Maarten Schmidt (1929–)	Discovery of the first Quasar.
1957		Sputnik 1 (USSR) first artificial satellite.
1961		Venera 1 (USSR) first mission to another planet (Venus).
1969		Apollo 11 (USA) first men land on the Moon.
1972	Stephen Hawking (1942–), Jacob Bekenstein (1947–)	Thermodynamics of black holes.
1976		Viking 1 and 2 (USA) first successful unmanned landing on Mars.
1979		Voyager 1 and 2 (USA) fly by Jupiter.
1980–1981		Voyager 1 and 2 fly by Saturn.
1981		First space flight of the (NASA) Shuttle space orbiter.
1986		Voyager 2 fly by of Uranus.
1989		Voyager 2 fly by of Neptune.
1990		Hubble Space Telescope (USA/ESA) launched.
1998		Initiation of the construction of the International Space Station in outer space orbiting earth.
2011		Last space flight of the Space Shuttle space orbiter program.

Atomic

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 550 BC	Thales of Miletus (ca. 640 BC–546 BC)	Documented the magnetic attractive properties of rubbed amber and of lodestone.
ca. 450 BC	Leucippus (5th century BC)	Proposed an atomic concept of matter.
ca. 400 BC	Democritus of Abdera (ca. 460 BC–357 BC)	Student of Leucippus, one of the most famous of the atomists in ancient times. Democritus stated: “The only existing things are the atoms and empty space; all else is mere opinion.”
ca. 335 BC	Aristotle (384 BC–322 BC)	Proposing that all matter was basically composed of the same “equal” continuous primordial material.
ca. 300 BC	Epicurus of Samos (ca. 342 BC–270 BC)	Philosophical system based on the atomism hypothesis expressed by Democritus.
ca. 300 BC	Zeno of Cition (ca. 336 BC–264 BC)	Foundation of the Stoic school of philosophy, based on the premise that matter, space, and natural phenomena were continuous.
ca. 60 BC	Titus Lucretius Carus (ca. 96 BC–55 BC)	Formulation explaining natural phenomena by implementation of the beliefs of Democritus and Epicurus. His poem: “De Rerum Natura,” is the most comprehensive record of the Greek atomism stream of thought. The atomism of ancient times was primarily a metaphysics concept. The atomic view of matter in the modern interpretation was introduced only in its most elementary form by the beginning of the nineteenth century.
ca. 400	Saint Augustine (Aurelius Augustinus) (354–430)	Documentation of the impression that the forces exerted by rubbed amber (electric) and by lodestone (magnetic) are fundamentally different properties.
ca. 1600	William Gilbert (1540–1603)	First detailed study of magnetism and additionally for electrical phenomena showed that, in addition to amber, many other materials can be electrical charged (electrified).
1638	Galileo Galilei (1564–1642)	Description of two additional sciences with respect to “mechanics” and “local motions” in the publication: “Discors e Dimostrazioni Matematiche intorno a due nuove Scienze attenti alla Mecanica e Movimenti locali” (<i>Discourses and Mathematical Demonstrations</i>). This establishes Galileo Galilei as the founder of dynamics, with fall-out to atomic and particle physics.
1650–1700	Robert Boyle (1627–1691), Robert Hooke (1635–1703), and Sir Isaac Newton (1642–1727)	Qualitative explanations of Boyle’s gas law, assuming an indivisible unit forming the basis for the gas (the unknown atom), by assuming a kinetic theory of gases.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1675	Jean Picard (1620–1682)	Observation of a luminous glow (radiation) in the Torricellian vacuum of a mercury barometer resulting from the motion of the mercury when the instrument was transported.
1675	Sir Isaac Newton (1642–1727)	Introduction of the corpuscular theory of light.
1705	Francis Hauksbee (1666–1713)	Construction and operation of a powerful electrostatic generator and documented discovery of the conditions producing luminous electric discharges in gases.
1731	Stephen Gray (1666–1736)	Discovery of the electrical conduction principles.
1734	Charles Francois De Cisternay du Fay (1698–1739)	Showed that there are two kinds of electrification: resinous and vitreous, and then proposed a two-fluid theory of electric discharge. He also found that the air in the vicinity of a hot body is conducting.
1752	Benjamin Franklin (1707–1790)	Experimentally verification of the hypothesized electrical nature of lightning and introduced the one-fluid theory of flow for the concept of electricity—from surplus of positive to deficiency or negative (assuming flow of positive charges). The theory of Ben Franklin contained the first essential statement of the law of conservation of electric charge.
1753	John Canton (1718–1772)	Discovery of electrostatic induction.
1766	Henry Cavendish (1731–1810)	Discovery of hydrogen. Cavendish described the inverse square law of force action between electric charges and significant additional laws of electricity but unfortunately he largely withheld announcement of his experimental observations. The work by Henry Cavendish was not known until James Clerk Maxwell (1831–1879) published his papers in 1879.
1785	Charles Augustin Coulomb (1736–1806)	Definition of the law of force between electric charges.
1789	Antoine Laurent Lavoisier (1734–1794)	Publication of the particle aspect for chemical elements and the verification of the law of conservation of matter in chemical reactions.
1791	Bryan Higgins (1737–1820) and William Higgins (1769–1825)	Documentation of the first of a series of experiments resulting in the formulation of the laws of chemical combination.
1799	Joseph Louis Proust (1754–1826)	Introduction of the law of definite proportions for chemical compounds.
1803	John Dalton (1766–1844)	Publication of the first of a series of papers introducing the concept of atomic weights. Additional statements established the law of multiple proportions, and specifically introducing the atomic theory of matter.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1811	Lorenzo Romano Amedeo Avogadro (1776–1856)	Introduction of Avogadro's hypothesis and differentiation between atoms and molecules.
1813	Jons Jacob Berzelius (1779–1848)	Introduction of the presently known and used system of symbols for the chemical elements.
1815	William Prout (1875–1850)	Hypothesis that all elements are composed of an integral number of hydrogen atoms, described by Henry Cavendish (1731–1810) in 1766.
1815–1820	Joseph Fraunhofer (1787–1826)	Noted the spectral lines of several elements, obtained the first grating spectra, and observed the Fraunhofer (absorption) lines in solar spectra. Indication of the future recognition of the energy levels in the atomic structure (electron orbits) of elements.
1819	Pierre Louis Dulong (1785–1838) and Alexis Therese Petit (1791–1821)	Recognized the law of constancy of molar specific heat capacities of elements.
1820	Hans Christian Ørsted [Oersted] (1777–1851)	Discovery that an electric current produces a magnetic field. This revelation initiated the study of electromagnetism.
1821	Thomas Johann Seebeck (1770–1831)	Discovery of thermoelectricity.
1823	Andre Marie Ampere (1775–1836)	Published his mathematical theory of electromagnetism and the laws of magnetic field produced by currents. Some of these laws were also discovered independently by Jean-Baptiste Biot (1774–1862) and Félix Savart (1791–1841).
1826	Georg Simon Ohm (1787–1854)	Introduction of Ohm's law.
1827	Robert Brown (1773–1858)	Discovery of the concept of Brownian movement.
1833	Michael Faraday (1791–1867)	Discovery of electrolysis and introduced the terms “anode” and “cathode,” with the associate flow of electrical charges.
1850–1900	August Karl Krönig (1822–1879), Rudolf Julius Emanuel Clausius (1822–1888), James Clerk Maxwell (1831–1879), Ludwig Boltzmann (1844–1906), and Josiah Willard Gibbs (1839–1903)	Kinetic theory of gases. Introduction of statistical mechanics. James Clerk Maxwell derived the velocity distribution law in 1860, Emanuel Clausius introduced the thermodynamic concept of entropy in 1865, and Ludwig Boltzmann related entropy to thermodynamic probability in 1877.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1858	Stanislao Cannizzaro (1826–1910)	Redefined the conflicting values of atomic weights by clarifying the terms “atomic,” “molecular,” and “equivalent” weights.
1859	Heinrich Geissler (1814–1879) and Julius Plucker (1801–1868)	Discovery of the “particle rays” (now known as cathode rays) from the negative electrode in gaseous discharge tubes, what we current know are electrons.
1860	Robert Wilhelm Eberhard Bunsen (1811–1899) and Gustav Robert Kirchhoff (1824–1887)	Recordings of the emission spectra of alkali metals in flames. Recognition of dark lines in the spectrum arising from absorption when illuminated by a bright light source through the flame. These dark lines are identical to the spectral lines observed in the solar spectrum observed by William Hyde Wollaston (1766–1828) and Joseph von Fraunhofer (1787–1826) in 1803: Fraunhofer lines, and it was argued that these lines in the sunlight are due to the absorption of light by gases in the solar atmosphere that are cooler than those “emitting the light” (not much was known about the mechanism of action of the sun), based on contemporary knowledge an oxidizing gas produces light.
1863	James Alexander Reina Newlands (1837–1898)	Stated the law of octaves for chemical structures, a limited and elementary form of the periodic table of the elements.
1865	Joseph Loschmidt (1821–1895)	Application of the equations of the kinetic theory of gases to allow for the first determination of Avogadro’s number and of molecular diameters.
1869	Dmitri Ivanovich Mendeleev (1834–1907) and Julius Lothar Meyer (1830–1895)	Both independently introduced the periodic table of the elements, a concise summary of years of documented experimental and theoretical chemistry. The table is both heuristic and mnemonic.
1869	Johann Wilhelm Hittorf (1824–1914)	Observation of the deflection of cathode rays in a discharge tube, by means of a magnetic field.
1871	Cromwell Fleetwood Varley (1828–1883)	Recognition that the cathode rays are negatively charged.
1874	Jacobus Hendricus van’t Hoff (1852–1911) and Joseph Achille Le Bel (1847–1930)	Description of the Carbon atom. Explanation of chirality (existence of two enantiomeric forms, virtually identical, but in actuality represent different molecules) based on the carbon atom asymmetry. Van’t Hoff introduces the four (4) different types of chemical bonds, all available for carbon based structures. These four separate chemical bonds provide the mechanism of action for the tetrahedron configuration, providing different three-dimensional atomic arrangements for the same chemical formula. This applies in particular to organic chemistry

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1876	Eugen Goldstein (1850–1930)	Introduction of the expression “cathode rays” and initiated experiments which eventually led to the discovery of the positive counterpart of the electron: Kanalstrahlen, meaning channel or canal rays. In 1886 Goldstein suggested that the aurora in the polar sky is due to cathode rays emerging from the sun, in fact these are a more complex range of ionizing particles.
1877	William Ramsay (1852–1916) next to Joseph Delsaulx (1828–1891), and Ignace J. J. Carbonelle (1829–1889)	Elaborated the first rather complete qualitative explanation of Brownian movement by attributing it to molecular impact. William Ramsay discovered several of the noble gases a few later, and he also made significant contributions to the study of radioactivity. He was awarded the Nobel Prize in Chemistry in 1904.
1879	William Crookes (1832–1919)	Initiated a series of experiments on the discharge of electricity through gases.
1881	Julius Elster (1854–1920), and Hans Friedrich Geitel (1855–1923)	Systematic investigation of the respective electrical effects produced by a broad range of incandescent solids.
1883	Thomas Alva Edison (1847–1931)	Recognition of the emission of negative electricity from incandescent filaments in a vacuum: Edison effect.
1884	Johann Jakob Balmer (1825–1898)	Derivation of an empirical relation for a spectral series of hydrogen as a function of wavelength. This was the first series equation found for any spectrum: Balmer series, linking atomic energy levels to spectral representations.
1887	Svante August Arrhenius (1859–1927)	Conclusively verified the ion dissociation theory of electrolytes which evolved from thermodynamic suggestions made by Rudolf Julius Emanuel Clausius (1822–1888) over the period 1850–1857. In 1903 Arrhenius was awarded the Nobel Prize in Chemistry.
1887	Heinrich Rudolph Hertz (1857–1894)	Description of the photoelectric effect while verifying the existence of the electromagnetic waves predicted by James Clerk Maxwell (1831–1879).
1888	Wilhelm Hallwachs (1859–1922)	Illustrated that only negative charges are emitted during the photoelectric effect.
1893	Philipp Eduard Anton Von Lenard (1862–1947)	Investigation of cathode rays by forcing them to pass through a Lenard window (thin window) tube into air. In 1905, Philipp Von Lenard was awarded the Nobel Prize in Physics for this and later work.
1895	Jean Baptiste Perrin (1870–1942)	Conclusively affirmation that cathode rays are negatively charged. In 1926 Jean Baptiste Perrin was awarded the Nobel Prize in Physics for this and later work.
1895	Wilhelm Conrad Roentgen (1845–1923)	Discovery of X-rays. Wilhelm Conrad Röntgen was awarded the Nobel Prize in Physics in 1901.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1896	Antoine Henri Becquerel (1852–1908)	Discovery of the radioactivity of the element uranium. He was awarded the Nobel Prize in Physics jointly with Marie Skłodowska Curie (1867–1934) and Pierre Curie (1859–1906) in 1903.
1896	Pieter Zeeman (1865–1943)	Observation of the splitting of spectral lines emitted by excited atoms while exposed to an intense external magnetic field. An earlier version of the theory of this effect was described by Hendrik Antoon Lorentz (1853–1928). They were jointly awarded the Nobel prize in Physics in 1902.
1897	Joseph John Thomson (1856–1940)	Determination of the electric charge value over the mass for cathode rays. In 1906 J. J. Thomson was awarded the Nobel Prize in Physics for this work.
1897	Ernest Rutherford (Lord Rutherford Of Nelson, 1st Baron) (1871–1937)	Experimental illustration that the radiation emitted by uranium was complex, consisting of “hard” (beta) rays as well as “soft” (alpha) rays. In 1908, Lord Rayleigh was awarded the Nobel Prize in Physics for this and for later work, he was awarded the Nobel Prize in Chemistry in 1908.
1898	Pierre Curie (1859–1906) and Marie Skłodowska Curie (1867–1934)	Isolation of the elements radium and polonium. They were awarded the Nobel Prize in Physics jointly with Antoine Henri Becquerel (1852–1908) in 1903. In 1911 Marie Curie was awarded the Nobel Prize in Physics for this work.
1899	Antoine Henri Becquerel (1852–1908), Stefan Meyer (1872–1949), Egon Von Schweidler (1873–1948), and Frederick Otto Giesel (1852–1927)	Independently observed the magnetic deflection of alpha and beta rays.
1899	Julius Elster (1854–1920) and Hans Geitel (1855–1923)	Experimental determination of the law of radioactive decay.
1899	Philipp Eduard Anton Von Lenard (1862–1947)	Experimental verification that photoelectric emission is due to electrons.
1899	Joseph John Thomson (1856–1940)	Explanation of the Edison effect is due to electrons.
1900	Antoine Henri Becquerel (1852–1908)	Experimental verification that beta rays are identical to the corpuscle character of cathode ray.
1900	Paul Villard (1860–1934)	Discovery of gamma rays.
1902	Philipp Eduard Anton Von Lenard (1862–1947)	Discovery of the photoelectric threshold frequency (i.e., minimum energy requirement) and additionally that the kinetic energy of photoelectrons is independent of the radiance of the incident light.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1903	Ernest Rutherford (Lord Rutherford of Nelson, 1st Baron) (1871–1937), and Frederic Soddy (1877–1956)	Illustrated that every radioactive process is a transmutation of elements. Frederic Soddy received the Nobel Prize in Chemistry in 1921.
1903	William Crookes (1832–1919), next to Julius Elster (1854–1920) and Hans Friedrich Geitel (1855–1923)	Uncovered that the luminescence produced when alpha particles strike zinc sulfide consists of discrete flashes of light of scintillations. This led to a method of counting individual alpha particles.
1904	William Ramsay (1852–1916) and Frederic Soddy (1877–1956)	Discovery of the remarkable recurrence of helium in all radium compounds.
1904	John Ambrose Fleming (1849–1945)	Application of the Edison effect to make the first thermionic valve (“radio” tube).
1904	Marian Von Smoluchowski (1872–1919)	Introduction of a statistical theory of Brownian movement.
1905	Albert Einstein (1879–1955)	Finalized the statistical theory of Brownian movement, based on the work of Marian Von Smoluchowski (1872–1919), introduction of the quantum explanation of the photoelectric effect, and published the special theory of relativity. Albert Einstein was awarded the Nobel Prize in Physics in 1921.
1905	Egon Von Schweidler (1873–1948)	Derivation of the law of radioactive decay based on probability theory, since it was not obtainable from causality.
1906	Owen Willans Richardson (1879–1959)	Series of important investigations regarding the emission of electricity from hot bodies: thermionic emission. Owen Willans Richardson was awarded the Nobel Prize in Physics in 1928.
1907–1912	Joseph John Thomson (1856–1940)	Devised methods of positive-ray analysis. These processes formed the beginning of mass spectroscopy.
1908	Charles Glover Barkla (1877–1944)	Discovery of the fact that the secondary X-rays of various elements are composed of groups of characteristic X-rays based on absorption experiments. Charles Barkla called these lines the K, L, and 117 radiations. He also demonstrated the polarization of X-rays. Charles Glover Barkla was awarded the Nobel Prize in Physics in 1917.
1908	Jean Baptiste Perrin (1870–1942)	Experimentally verification of several equations for Brownian movement. Perrin obtained more accurate values for Avogadro’s number, and illustrated that equipartition of energy is verified for small particles suspended in a stationary liquid.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1908–1910	Alfred Heinrich Bucherer (1863–1927), Karl Erich Hupka (1884–1919), Charles Eugene Guye (1866–1942), and Simon Ratnowsky (1884–1945)	Independent precision measurements of the mass of an electron as a function of the velocity of the electron. The results confirmed the Lorentz–Einstein mass variation relation.
1909	Ernest Rutherford (Lord Rutherford of Nelson, 1st Baron) (1871–1937) and Thomas Royds (1884–1955)	Experimentally illustrated that alpha particles are doubly ionized helium atoms, that is, helium nucleus.
1909–1910	Theodor Wulf (1868–1946) next to Albert Gockel (1860–1927)	Observation of charge leak rate from a highly insulated electroscope placed at the top of the Eiffel Tower, Paris, France, next to a study of the same effects in balloon ascents up to 4500 meters. The independent studies found the rate of leakage greater than at the surface of the earth. Their results were unexpected at the time because the effect at ground level had been attributed to local radioactivity of the soil.
1909–1911	Robert Andrews Millikan (1868–1953)	Introduction of the law of multiple proportions for electric charges and made the first precise assessment of the value for electronic charge: Millikan's oil-drop experiment. Robert Millikan was awarded the Nobel Prize in Physics in 1923.
1911	Peter Joseph Wilhelm Debye (1884–1966)	Application of the quantum theory to obtain a rather complete theory of specific heats, and subsequently applied the quantum concept to many problems and enigmas in physical chemistry. Peter Debye was awarded the Nobel Prize in Chemistry in 1936.
1911–1913	Ernest Rutherford (Lord Rutherford of Nelson, 1st Baron) (1871–1937), Johannes Geiger (1882–1945), and Ernest Marsden (1889–1970)	Their experiments pertaining to alpha-particle scattering by thin metal foils illustrated that a nuclear model of the atom was required in order to explain the energy interaction
1911	Charles Thomson Bees Wilson (1869–1959)	Construction of the first expansion cloud chamber, used for particle research. This is one of the most important device in nuclear physics. Charles Wilson was awarded the Nobel Prize in Physics jointly with Arthur Holly Compton (1892–1962) in 1927.
1912	Max Theodor Felix von Laue (1879–1960), Walter Friedrich (1883–1969), and Paul C. M. Knipping (1883–1935)	Affirmation of the wave nature of X-rays by crystal diffraction. Max Theodor Felix von Laue received the Nobel Prize in Physics in 1914.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1912	Hans Geiger (1882–1945), and John Mitchell Nuttall (1890–1958)	Heuristic law relating the energy of an emitted alpha particle from a nucleus to the disintegration constant of the parent nucleus.
1913	Hans Geiger (1882–1945)	Detailed description of the radiation discharge counter tube which was developed from a simpler form first made in 1908: Geiger counter. This instrument was further improved in 1928.
1913	Frederic Soddy (1877–1956) and Kasimir Fajans (1887–1975)	Radioactive decay laws of displacement in the periodic table for elements. Frederick Soddy introduced the term “isotopes.”
1913	George Charles De Hevesy (1885–1966) and Fritz Adolf Paneth (1887–1959)	Application of an isotope of lead: radium D, to study the solubility and the chemistry of lead compounds. This was the first documented use of an isotope as a tracer element. George De Hevesy received the Nobel Prize in Chemistry for his work in 1943.
1913	Neils Henrik David Bohr (1885–1962)	Atom model in which the electrons were presumed to occupy stable orbits demarcated by well-defined energy levels. This theory underwrites the quantum aspect of the absorption and emission of light by an atom resulting from the acceleration of an electron moving from one orbit to another orbit of different energy. This also provides an explanation of the absorption and emission at particular frequencies that are characteristic for that particular atomic energy configuration, depending on the element in question. Niels Bohr was awarded the Nobel Prize in Physics in 1922.
1913	Johannes Stark (1874–1957)	Observation of the splitting of spectral lines radiated by excited atoms in an applied intense external electric field: Stark effect. Johannes Stark received the Nobel Prize in Physics in 1919.
1913	James Franck (1882–1964) and Gustav Hertz (1887–1975)	Provided experimental evidence supporting the Bohr atomic theory pertaining to ionization and resonance potentials. Both James Franck and Gustav Hertz were awarded the Nobel Prize in Physics in 1925.
1913	William Henry Bragg (1862–1942) and William Lawrence Bragg (1890–1971)	Studied X-ray “reflection” (scatter) from crystals (Bragg law) and devised an X-ray spectrometer. They were awarded the Nobel Prize in Physics in 1915.
1913	Niels Henrik David Bohr (1885–1962)	Bohr atomic model.
1913	Frederick Soddy (1877–1956)	Formal introduction of the isotope concept.
1914	Niels Henrik David Bohr (1885–1962)	Description of the atomic energy layer model; hydrogen (Bohr atomic model).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1914	Henry Gwyn Jeffrey Moseley (1884–1915)	X-ray spectrograms of the elements which assisted in the establishment of the identity of the ordinal number of respective elements in the periodic table associated with its nuclear charge: atomic number.
1914	Karl Manne Georg Siegbahn (1886–1978)	Series of pioneering efforts in the theory and application of precision X-ray spectroscopy. Karl Siegbahn received the Nobel Prize in Physics in 1924.
1915	Sir Ernest Marsden (1889–1970)	Artificial transmutation, associated with the element radon enclosed by vacuum.
1915	Arnold Johannes Wilhelm Sommerfeld (1868–1951)	Improvements to the Bohr atomic model by introducing elliptical orbits and relativistic effects.
1915	William Duane (1872–1935) and Franklin Livingston Hunt (1883–1973)	Computational proof that the short-wavelength limit of emitted radiation is determined by the quantum theory.
1915	Albert Einstein (1879–1955)	Introduction of the general theory of relativity, describing the conditions that apply to the observations of phenomena on accelerated reference frames.
1916	Robert Andrews Millikan (1868–1953)	Experimental verification of Einstein's photoelectric equation.
1916	Peter Joseph Wilhelm Debye (1884–1966), Paul Scherrer (1890–1969), next to Albert Wallace Hull (1880–1966)	Obtained the first experimental x-ray powder diffraction patterns.
1916	Theodore Lyman (1874–1954)	Atomic absorption\emission series for hydrogen providing the Lyman series lines predicted by the Niels Henrik David Bohr (1885–1962) theory of the hydrogen atom. Theodore Lyman had documented observing at least one of these lines as early as 1906.
1918	Paul Scherrer (1890–1969)	X-ray diffraction, crystal structure. Nuclear energy development. Established the CERN institute in Switzerland as one of the founders. Directed the construction of the first cyclotron in 1940.
1919	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Artificial transmutation, hydrogen formation resulting from collisions of alpha particles with nitrogen, also generating oxygen and gamma rays.
1919	Ernest Rutherford (Lord Rutherford of Nelson, 1st Baron) (1871–1937)	Alpha particle bombardment of nitrogen producing hydrogen and oxygen, the first “man-made” transmutation of an element.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1919	Francis William Aston (1877–1945)	First high-precision determination series measurements of isotopic masses. Francis Aston received the Nobel prize in Chemistry in 1922.
1921	James Chadwick (1891–1974) and Étienne Samuel Biéler (1895–1929)	Strong nuclear force.
1921	Otto Stern (1888–1969) and Walter Gerlach (1889–1979)	Verification of the space quantization for silver atoms exposed to a magnetic field while measuring their magnetic moment. Otto Stern received the Nobel Prize in Physics in 1943.
1923	Arthur Holly Compton (1892–1962)	Discovery of the Compton effect, verifying that a photon has momentum. Arthur Holly Compton received the Nobel Prize in Physics jointly with Charles Thomson Rees Wilson (1869–1959) in 1927.
1923	Arthur Holly Compton (1892–1962)	Description of the deflection of photons by a charge unit, generally an electron, potentially the nucleus: Compton effect
1924	Edward Victor Appleton (1892–1965), Arthur Edwin Kennelly (1861–1939) next to Oliver Heaviside (1850–1925)	Initiation of a series of experiments that established the existence and properties of ionized layers in the upper atmosphere. The existence of this type of layers had been postulated by Arthur Edwin Kennelly (1861–1939) in 1902 and, independently, by Oliver Heaviside (1850–1925) to explain the observed implications for long-distance wireless telegraphy. Edward Appleton received the Nobel Prize in Physics in 1947.
1924	Satyendra Nath Bose (India, 1894–1974) next to Albert Einstein (1879–1955)	Independent introduction of the statistical formulation “obeyed” by bosons; a collective name for photons, nuclei of even mass number, and specific other particles.
1925	Johannes Geiger (1822–1945) and Walther Wilhelm Georg Bothe (1891–1957)	Conservation of energy for atomic and nuclear processes.
1925	Werner Karl Heisenberg (1901–1976)	Uncertainty principle.
~1925	Friedrich Hermann Hund (1896–1997)	Recognition of the “Coulomb barrier” in nuclear collision, providing a “tunneling” effect for the release of alpha particles. Also recognized as “quantum tunneling.”
1924	Louis Victor Duc De Broglie (1892–1987)	Introduced the concept of de Broglie waves, the beginning of the wave theory of matter. Louis Victor, Duc De Broglie received the Nobel Prize in Physics in 1929.
1925	Walter M. Elsasser (1904–1991)	Predicted from de Broglie theory illustrating how electrons could be diffracted by crystals.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1925	Charles Drummond Ellis (1895–1980) and William A. Wooster (1903–1984)	Established that in a number of elements the emission of either an alpha or a beta particle precedes the radiation of gamma rays, and thus the latter should be associated with the daughter product, not with the parent.
1925	Pierre Victor Auger (1899–1993)	Discovery of a type of energy transition in which an electron in an atom transitions from a higher to a lower energy state by ejecting one of its own electrons, however, without the emission of electromagnetic radiation: Auger electron. This phenomenon was reported also by Lise Meitner (1878–1968) around the same time.
1925	George Eugene Uhlenbeck (1900–1988) and Samuel Abraham Goudsmit (1902–1978)	Introduction of spin and magnetic moment of the electron into atomic theory.
1925	Wolfgang Pauli (1900–1958)	Announced the exclusion principle. Wolfgang Pauli received the Nobel Prize in Physics in 1945.
1925	Patrick Maynard Stuart Blackett (1897–1974)	Obtained the first cloud chamber tracks of the induced transmutation of nitrogen and of other elements, and later made many cosmic ray studies. He was awarded the Nobel Prize in Physics in 1948.
1925	Max Born (1882–1970) and Werner Karl Heisenberg (1901–1976), and Pascual Jordan (1902–1980)	Development of quantum mechanics principles. Later, Born originated the statistical interpretation of wave mechanics. Max Born received the Nobel Prize in Physics jointly with Walther Wilhelm Georg Bothe (1891–1957) in 1954.
1926	Erwin Schrödinger (1887–1961)	Introduction of the wave mechanical theory for the hydrogen atom. Erwin Schrödinger was awarded the Nobel Prize in Physics and shared it with Paul Adrien Maurice Dirac (1902–1984) in 1933.
1926	Enrico Fermi (1901–1954) and Paul Adrien Maurice Dirac (1902–1984)	Independent introduction of the statistical formulation “obeyed” by fermions, a collective name for electrons, nuclei of odd mass number, some particles, and in particular the electron gas in a conductor. Both Enrico Fermi and Paul Adrien Maurice Dirac were awarded the Nobel Prize for work listed at a later time in this chronology.
1926	Eugene Paul Wigner (1902–1995)	Series publications on the application of group theory in quantum mechanics. Eugene Wigner shared the Nobel Prize in Physics jointly with Maria Goeppert-Mayer (Göppert) and Johannes Hans Daniel Jensen (1907–1973) in 1963.
1927	Werner Karl Heisenberg (1901–1976)	Announcement of the uncertainty principle; “Unbestimmtheit Prinzip.” Karl Heisenberg received the Nobel Prize in Physics in 1932.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1927	Clinton Joseph Davisson (1881–1958), Lester Halbert Germer (1896–1971), and George Paget Thomson (1892–1975)	Electron diffraction from single crystals, and additionally George Paget Thomson obtained powder electron diffraction patterns. This work validated the existence of de Broglie waves. Clinton Davisson and George Thomson shared the Nobel Prize in Physics in 1937.
1927	Werner Karl Heisenberg (1901–1976)	Quantum uncertainty principle.
1927	Paul Adrien Maurice Dirac (1902–1984)	Description of antimatter.
1928	Edward Uhler Condon (1902–1974) and Ronald Wilfrid Gurney (1898–1953) next to George Gamow (1904–1968)	Solution to the nuclear problem of alpha particle emission using wave mechanics and they derived the Geiger–Nuttall law, in reference to the work of Johannes Geiger (1822–1945) and John Mitchell Nuttall (1890–1958).
1928	Paul Adrien Maurice Dirac (1902–1984)	Introduction of relativistic quantum mechanics and prediction of the existence of the positron. Paul Dirac shared the Nobel Prize in Physics with Erwin Schrödinger (1887–1961) in 1933.
1928	Chandrasekhara Venkata Raman (1888–1970)	Description of the Raman effect. This is the presence of frequencies differing from that of the incident light resulting from scattered by molecules. The shifts in frequency are characteristic of the scattering substance (molecular energy information) and independent of the incident frequency. Chandrasekhara Raman received the Nobel Prize in Physics in 1930.
1928	Dmitri Vladimirovich Skobeltsyn (1892)	Construction of the first cloud chamber, producing photographs of cosmic rays. These photographs revealed that cosmic rays either were, or produced, many charged, high-energy particles.
1928	Hans Geiger (1882–1945) and Walther Müller (1905–1979)	Improved form of the 1913 Geiger counter, referred to as the Geiger–Müller counter.
1928	Walther Wilhelm Georg Franz Bothe (1891–1957) and Werner Heinrich Gustav Kolhörster (1887–1946)	Application of Geiger–Müller tubes to make coincidence counters and other innovative devices specifically designed for high sensitivity cosmic-radiation study. Walther Bothe shared the Nobel Prize in Physics with Max Born (1882–1970) in 1954.
1928	Johannes Geiger (1822–1945) and Walther Müller (1905–1979)	Introduction of an improved Geiger counter: the Geiger–Müller counter, using ionization of a confined gas.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1929	Leo Szilard (1898–1964) and Ernest Orlando Lawrence (1901–1958)	Particle accelerator: cyclotron. The cyclotron can accelerate protons to reach kinetic energy in excess of 700 MeV, with respective radius of 4.6 meter (1946). The first cyclotron was built in 1932, at the University of California Berkeley, California: Tevatron. Cyclotrons are specifically not exclusively, used to create isotopes for use in nuclear medicine, in particular for imaging (e.g., PET) and for cancer treatment.
1929	Otto Stern (1888)	Obtained crystal diffraction of a beam of helium atoms.
1930	Fredrik Carl Muelertz Stoermer (1874–1957), Georges Lemaitre (1894–1966), and Manuel Sandoval Vallarta (1899–1977)	Applied the theory of the motion of charged particles in the earth's magnetic field, originally developed to account for the aurora borealis, to integrate cosmic rays. This theory of the cause of geomagnetic effects was greatly expanded in 1933 by Georges Lemaitre Manuel Sandoval Vallarta. Additional theoretical work was implemented by William Francis Gray Swann (1884–1962) and others.
1930–1933	Ira Forry Zartman (1899–1981)	Experimental verification of the Maxwell distribution law of molecular velocities; Maxwell–Boltzmann distribution.
1931	Thomas Hope Johnson (1899–1998)	Experimental crystal diffraction of a beam of hydrogen atoms.
1931	Robert Jemison Van De Graaff (1901–1967)	First reliable, high-voltage, electrostatic generator for nuclear research.
1931	Wolfgang Ernest Pauli (1900–1958)	Expressed the hypothesis of beta decay processes postulating that a “new,” small, neutral particle (the neutron) should be emitted concurrently with the electron. Energy when involved in beta decay up to 0.5 MeV. The experimental verification of the existence of the neutrino was not until 1956 by Frederick Reines (1918–1998) and Clyde Cowan Jr. (1919–1974).
1931	Carl David Anderson (1905–1991)	Discovery of the positron, anti-particle for the electron. The “positron” was predicted by Paul Adrien Maurice Dirac (1902–1984) in 1929. Carl Anderson received the 1936 Nobel Prize in Physics for this discovery in 1936, and he also discovered the muon in 1936.
1931	Harold Clayton Urey (1893–1981), Ferdinand Graft Brickwedde (1903–1989), and George Moseley Murphy (1905–1968)	Discovery of deuterium and composition of the first “heavy water.” Harold Urey received the Nobel Prize for Chemistry in 1934.
1931	Carl David Anderson (1905–1991)	Discovery of the positron, anti-particle for the electron. The “positron” was predicted by Paul Adrien Maurice Dirac (1902–1984) in 1929.
1932	Sir James Chadwick (1891–1974)	Discovery of the neutron. Student of Ernest Rutherford (1871–1937).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1932	Ernest Orlando Lawrence (1901–1958) and Milton Stanley Livingston (1905–1986)	Construction of the first cyclotron. Ernest Lawrence was awarded the Nobel Prize in Physics in 1939.
1932	Sir John Douglas Cockcroft (1897–1967) and Ernest Thomas Sinton Walton (1903–1995)	Facilitated the transmutation of lithium by impaling by high-energy protons, and hence provided the first direct verification of the Einstein law for mass–energy equivalence. This experiment denotes the first time a high-voltage accelerator was successfully used to produce a nuclear reaction. Sir John Cockcroft and Ernest Walton shared Nobel Prize in Physics in 1951 for their work.
1932	James Chadwick (1891–1974)	Discovery of the neutron. This particle accounted for the penetrating “radiation” described by Walther Wilhelm Georg Bothe (1891–1957) and Herbert Becker (?). James Chadwick was awarded the Nobel Prize in Physics in 1935.
1932	Bruno Benedetto Rossi (1905–1993)	Realization that there is an initial increase in radiance under “transmittance” through an absorbing layer. Bruno Rossi associated this with cosmic ray showers. A transition to decreasing radiance was achieved when the layer thickness exceeded a certain value.
1932	Carl David Anderson (1905–1991)	Discovery of the positron during cosmic ray research. Carl David Anderson shared the Nobel Prize in Physics with Victor Francis Hess (1883–1964) in 1936.
1933	Patrick M. S. Blackett (1897–1974) and Giuseppe P. S. Occhialini (1907–1993)	Electron–positron pair production under cloud chamber observation; first cloud chamber photographs.
1933	Jean Valentin Thibaud (1901–1960) and Frederic Joliot (1900–1958)	Detection of radiation produced by electron-positron annihilation. Jean Thibaud and Frederic Joliot also showed the equivalence of the mass of the positron to that of the electron.
1933	Thomas Hope Johnson (1899–1998) and Jabez Curry Street (1906–1989)	Observation that the cosmic ray radiance from the west is greater than what is emerging from the east. This east–west asymmetry illustrates the excess of positively charged particles in the primary cosmic ray trajectory coming in from outer space, with a significant contribution from the Sun.
1934	Pavel Alekseyevich Cherenkov (1904–1990) [Russian: Пáвeл Алeксéевич Чeрeнкóв], Igor Yevgenyevich Tamm (1895–1971) [Russian: Игoрь Евгéньевич Тaмм], and Ilya Mihajlovic Frank (1908–1990) [Russian: Илья Михайлович Фpaнк]	Pavel Cherenkov observed a weak, bluish glow in transparent media when irradiated by high-energy beta particles. The theoretical explanation for this Cherenkov radiation was given by Ilya Mihajlovic Frank and Igor Yevgenyevich Tamm three years later. These three scientists shared the Nobel Prize in Physics in 1958.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1934	Stjepan Mohorovičić (1890–1980)	Prediction of a transitory non-nuclear “element”; later named positronium. This formation precedes electron–positron annihilation.
1934	Irene Joliot-Curie (1897–1956) and Frederic Joliot (1900–1958)	Discovery of artificial radioactivity. Irene Joliot-Curie and Frederic Joliot shared the Nobel prize in chemistry in 1935.
1934	Enrico Fermi (1901–1954), Edoardo Amaldi (1908–1989), Oscar D’Agostino (1901–1975), Franco Dino Rasetti (1901–2001), and Emilio Gino Segre (1905–1989)	Enrico Fermi developed Pauli’s theory of beta decay and named the “new” particle the neutrino (little neutron). It is postulated in Fermi’s theory that the neutron is radioactive, disintegrating into a proton with the formation of an electron and a neutrino just before beta emission. Fermi also began a series of experiments in collaboration to produce transuranic elements by irradiating uranium with neutrons. They were granted a patent on the graphite moderator in 1955. Fermi was awarded the Nobel Prize in Physics in 1938.
1934	Leo Szilard (1898–1964)	Recognition of nuclear decay chain reactions.
1934	Hideki Yukawa [湯川 秀樹], (1907–1981)	Introduction of mesons and the initial concept of anti-matter. In 1935 Hideki Yukawa postulation of his theory of nuclear binding resulting from a particle that has a mass that lies between that for an electron and a proton. Hideki Yukawa received the Nobel Prize in Physics for this work in 1949.
1934	Ida Noddack (1896–1978)	Formal introduction of the concept of “fission,” however not recognized by her peers at the time. The fission phenomenon was only recognized when announced by Enrico Fermi (1901–1954) later that year.
1934	Enrico Fermi (1901–1954)	Interaction of slow neutron with nuclei and the resulting decay into different elements, including aluminum and uranium
1935	Arthur Dempster (1886–1950)	Discovery of the lighter uranium isotope: uranium-235
1935–1939	Isidor Isaac Rabi (1898–1988)	Precise determination of the nuclear magnetic moment within rays of atoms using an experimental set-up constructed with his radio frequency resonance method. Isidor Isaac Rabi received the Nobel Prize in Physics in 1944.
1936	Carl David Anderson (1905–1991) and Seth Henry Neddermeyer (1907–1988)	Discovery of a particle of the type postulated by Yukawa, observed during cosmic ray research The new particle was called “mesotron,” later renamed as “meson.”
1936	Marietta Blau (1894–1970)	First experimentalist to systematically make use of nuclear track plates.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1936	Otto Hahn (1879–1968) and Lise Meitner (1878–1968)	Neutron collision of uranium-induced decay examination.
1937	Carl David Anderson (1905–1991), Seth Henry Neddermeyer (1907–1988), Jabez Curry Street (1906–1989), and Edward C. Stevenson (20th century)	Confirmation of the existence of the meson and muon. Subatomic particles are governed by quantum physics principles, and will exhibit a wave–particle duality. The quantum state energy vectors are represented in Hilbert space.
1937	Niels Henrik David Bohr (1885–1962)	Introduction of the liquid drop model or the atomic nucleus.
1938	Irene Joliot-Curie (1897–1956) and Pavle Savic/Savitch (1903–1994)	Discovery of lanthanum in uranium after irradiation by neutrons.
1938	Otto Hahn (1879–1968) and Fritz Strassmann (1902–1980)	Bombarding uranium with neutrons produces alkali earth elements. Otto Hahn received the Nobel Prize in Chemistry in 1944.
1938	Niels Henrik David Bohr (1885–1962) and John Archibald Wheeler (1911–2008)	Formal description of the nuclear fission process.
1939	Jerome M. B. Kellogg (1905)	Discovery of a finite quadruple moment for the deuteron, requiring a non-central (tensor) nuclear force configuration.
1939	Lise Meitner (1878–1968) and Otto Robert Frisch (1904–1979)	Nuclear splitting in an attempt to explain the result from Otto Hahn (1879–1968) on the disintegration of uranium by neutron impact. They predicted the release of a substantial amount of energy resulting from fission.
1939	Niels Henrik David Bohr (1885–1962) and John Archibald Wheeler (1911–2008)	Introduction of theory of nuclear fission.
1939	Hans Albrecht Bethe (1906–2005) next to Carl Friedrich Von Weizsäcker (1912–2007)	Two groups that independently proposed two equivalent sets of nuclear reactions to account for stellar energies: the proton–proton chain and the carbon cycle.
1940	John Ray Dunning (1907–1975), Eugene Theodore Booth (1912–2004) and Aristid V. Grosse (1905–1980)	Experimental observation of the fission of U235, the less abundant isotope of uranium, by means of slow neutrons.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1940	Louis Leprince-Ringuet (1901–2000)	Obtained the first cloud chamber photograph of a collision between a meson and an electron, from which the mass of the meson could be derived.
1940	Donald William Kerst (1911–1993)	Construction of the first betatron, an induction type accelerator.
1940	Edwin Mattison McMillan (1907–1999), Philip Hague Abelson (1913–2004), Glenn Theodore Seaborg (1912–1999), Joseph William Kennedy (1916–1957), and Arthur Charles Wahl (1917–2006)	Production of the first transuranic element, neptunium. Additional work included the second transuranic element, plutonium. Edwin McMillan and Glenn Seaborg shared the Nobel Prize in Chemistry in 1951.
1940	Otto Robert Frisch (1904–1979)	Development of the detonation mechanism for the first atomic bomb.
1940+	Julius Robert Oppenheimer (1904–1967)	Manhattan project: fission reaction. Prominent members: Arthur Compton (1892–1962), Enrico Fermi (1901–1954), Eugene Wigner (1902–1995), and dozens more.
1942	Enrico Fermi (1901–1954) and Leo Szilard (1898–1964)	Design and construction of the first successful self-sustaining fission reactor, located in Chicago, Illinois. The reactor was first placed in operation on December 2 and produced a power level of one-half watt.
1945	J. Robert Oppenheimer (1904–1967)	Director of the Los Alamos Scientific Laboratory, managing a large select group of scientists engaged in a program of basic nuclear research and development. The culmination of this work was the detonation of the first nuclear bomb at Alamogordo, New Mexico, on July 16, 1945.
1945	Edwin Mattison McMillan (1907–1999) next to Vladimir Iosifovich Veksler (1907–1966)	Independent introduction of the principle of the synchrotron. The synchrotron accelerator produces very high-energy particles, as in the Cosmotron, Brookhaven National Laboratory, Upton, New York, operating at 3.3 GeV and revealed mesons generally only generated under cosmic ray interaction; or Bevatron, Lawrence Berkeley National Laboratory, Berkeley, California, operating a proton beam at 10 BeV.
1946	Felix Bloch (1905–1983) and Edward Mills Purcell (1912–1997)	Designed the magnetic induction method. Independently, both groups developed the magnetic resonance absorption method for the determination of nuclear magnetic moments, using both liquids or solids. Their work led to the nuclear resonance spectrometer. Felix Bloch and Edward Purcell received the Nobel Prize in Physics in 1952.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1946		Introduction of the term “Lepton,” defining weak nuclear interaction particles; electrons and muons are hence considered leptons.
1947	George Dixon Rochester (1908–2001) and Clifford Charles Butler (1922–1999)	Discovery of the subatomic particle: the “kaon,” k-meson. Introduction of the “strangeness” concept for quarks, although the quark concept had not been introduced. In the elementary particle phenomenology the kaon is a bound state of an up- or down quark with a strange quark (anti-quark).
1947	Maria Goeppert-Mayer (Göppert) (1906–1972)	Theoretical concept development for the understanding of nuclear forces, based on a shell model, similar to the atomic electron model.
1947	William Webster Hansen (1909–1949)	Linear accelerator installation at Stanford University, California.
1947	Polykarp Kusch (1911–1993)	High precision assessment of the magnetic moment for the electron. Polykarp Kusch discovered a small but theoretically significant difference between the predicted value of the moment and the experimental results. Polykarp Kusch shared the Nobel Prize in Physics with Willis Eugene Lamb (1913–2008) in 1955.
1947	Willis Eugene Lamb, Jr., (1913–2008) and Robert E. Retherford (1882–1939)	Description of the Lamb shift, observed during the course of spectral measurements of the fine structure of hydrogen in the microwave region. This small displacement of an energy level from its theoretical position was predicted by Dirac’s quantum theory of the electron (Paul Adrien Maurice Dirac [1902–1984]). Willis Lamb was awarded the Nobel Prize in Physics jointly with Polykarp Kusch (1911–1993) in 1955.
1947	Hans Albrecht Bethe (1906–) next to Julian Seymour Schwinger (1918–1994)	Explanation of the discrepancies published by Willis Eugene Lamb (1913–2008) and Polykarp Kusch (1911–1993) resulting from an interaction of electrons with an applied radiation field. Julia Schwinger shared the Nobel Prize in Physics with Richard Phillips Feynman (1918–1988) and Sin-Itiro Tomonaga [朝永 振一郎] (1906–1979) in 1965.
1947	Hartmut Paul Kallmann (1896–1978), next to John Wesley Coltman (1915–2010) next to Fitzhugh Ball Marshall (1912–1965)	Development of scintillation counters.
1947	Cecil Frank Powell (1903–1969), Giuseppe P. S. Occhialini (1907–1993), and Cesare Mansueto Giulio Lattes (1924–2005)	Discovery of the pi-meson. Cecil Powell received the Nobel Prize in Physics in 1950.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1947	George Dixon Rochester (1908–2001) and Clifford Charles Butler (1922–1999)	Discovery of V-particles and hyperons.
1948	Eugene Gardner (1913–1950) and Césaire Mansueto Giulio Lattes (1924–2005)	First artificial production of mesons in the laboratory.
1948–1950	Willard Frank Libby (1908–1980) and James Richard Arnold (1923–2012)	Development of radiocarbon dating with his group at the University of Chicago, Institute for Nuclear Studies (now Enrico Fermi Institute for Nuclear Studies). Carbon dating has a time range limit of approximately 50,000 years. Frank Libby received the Nobel Prize in Chemistry in 1960.
1949	Maria Goeppert-Mayer (Göppert) (1906–1972) next to Otto Haxel (1909–1998), Johannes Hans Daniel Jensen (1907–1973) and Hans Edward Suess (1909–1993)	Introduction of the shell theory of the nucleus, which assumes a spherical organization of nucleons, similar to that for the electrons. Maria Goeppert-Mayer (Göppert) and Johannes Jensen shared the Nobel Prize in Physics with Eugene Paul Wigner (1902–1995) in 1963.
1950	Arthur Hawley Snell (1909–1989) and John Michael Robson (1920–2000)	While at the Oak Ridge National Laboratory, in collaboration with the Chalk River Laboratory provided the experimental verified that the free neutron is radioactive.
1950		Scientists began intensified research on light-element fusion reactions.
1950	Maria Goeppert-Mayer (Göppert) (1906–1972)	Introduction of the nuclear shell model for atomic nuclei.
1951	Martin Deutsch (1917–2002)	Experimental confirmation of the prediction of the existence of positronium.
ca. 1952	Ludwig von Helmholtz (1821–1894), Lyman Strong Spitzer, Jr (1914–1997) and Ronald Richter (1909–1991) and Edward Teller (1908–2003)	Nuclear fusion investigation and start of experimentation. The process was in principle described by Hermann Ludwig Ferdinand von Helmholtz (1821–1894), but is continuously in action at the Sun's surface.
1952		Brookhaven National Laboratory was the first accelerator to achieve the acceleration of proton particles to the giga-electron-volt energy range: 2.3-GeV.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1952	Aage Niels Bohr (1922–2009), Benjamin Roy Mottelson (1926–) and Leo James Rainwater (1917–1986)	Unified (collective) shell model of the nucleus. This shell model assumes a nonspherical nuclear core. The possibility of a distorted core had been suggested in 1950 by Ben Mottelson (1926–) and James Rainwater, for which they shared the Nobel Prize in Physics in 1975, along with Aage Bohr for their contributions to the description of the nonspherical geometry of atomic nuclei.
1952	Donald Arthur Glaser (1926–2013)	Construction of the first bubble chamber. Donald Glaser received the Nobel Prize in Physics in 1960. This first large-scale, terrestrial thermonuclear reaction was produced when a “hydrogen fusion device” was being tested on the Einewetok atoll, Marshall islands, on November 1.
1953	Murray Gell-Mann (1929–)	Introduction of the strangeness “numbers” for nucleons, mesons, and hyperons. Gell-Mann recognized that strangeness is conserved when part of strong interactions.
1953	Robert Hofstadter (1915–1990)	Experimental observation of the scattering of high-energy electrons by atomic nuclei and atoms. The results obtained led to the determination of the charge distribution and structure of nuclei and nucleons. Hofstadter was awarded the Nobel Prize in Physics jointly with Rudolph Ludwig Mössbauer (1929–2011) in 1961.
1954	James Power Gordon (1928–2013), Herbert J. Zeiger (1925–2011), and Charles Hard Townes (1915–2015)	Construction of the first maser (molecular [formerly, microwave] amplification by stimulated emission of radiation). In this device configuration, many molecules can simultaneously be placed into high energy states and are subsequently induced to emit their energy as radiation under stimulation from a weak incoming signal of the same frequency. Charles Hard Townes shared the Nobel Prize in Physics with Nikolay Gennadiyevich Basov [Russian: Никола́й Генна́диевич Ба́сов] (1922–2001) and Alexander Mikhaylovich Prokhorov, [Russian: Алекса́ндр Миха́йлович Про́хоров] (1916–2002) in 1964.
1954	Chen-Ning Franklin Yang (1922–2004) and Robert Laurence Mills (1927–1999)	Introduction of “gauge theories.” These gauge theories will eventually form the basis for the “standard model.”
1955	Obninsk Nuclear Power Station, Russia	First nuclear power station for energy generation.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1955	Owen Chamberlain (1920–2006), Emilio Gino Segre (1905–1989), Clyde Edward Wiegand (1915–1996), and Thomas John Ypsilantis (1928–2000)	Creation of proton–antiproton pairs. Owen Chamberlain and Emilio Segre were awarded the Nobel Prize in Physics in 1959.
1956	Luis Walter Alvarez (1911–1988)	Cold fusion of deuterium using the negative mu-meson as a catalyst.
1956	John Bardeen (1908–1991), Walter Houser Brattain (1902–1987), and William Shockley (1910–1989)	These scientists shared the Nobel Prize in Physics in recognition of their work in the theoretical description of the solid state, in particular the semiconductor medium.
1956	Frederic Reines (1918–1998) and Clyde Lorrain Cowan, Jr. (1919–1974)	Experimental confirmation of the existence of the neutrino. Frederic Reines and Martin Lewis Perl (1927–2014) shared the Nobel Prize in Physics in 1995; since Clyde Lorrain Cowan, Jr. had passed away in 1974 he was not included since the Nobel Prize is awarded posthumously.
1956	Frederick Reines (1918–1998) and Clyde Cowan Jr. (1919–1974)	The experimental verification of the existence of the neutrino based on the 1931 work by Wolfgang Ernest Pauli (1900–1958).
1956		The world's first full-scale nuclear power plant was put into operation on October 17 at Calder Hall, England. The gas-cooled reactors develop 360 megawatts of thermal power to deliver 78 megawatts of electrical power.
1956	Tsung Dao Lee (1926–) and Chen Ning Yang (1922–)	Theoretical explanation that the law of conservation of parity, representing the invariance of spatial inversion, is invalid for weak interactions. They shared the Nobel Prize in Physics in 1957.
1956	Frederick Reines (1918–1998) and Clyde Lorrain Cowan Jr. (1919–1974)	Experimental confirmation of the neutrino introduced in 1931 by Wolfgang Pauli (1900–1958)
1956	Chien-Shiung Wu (1912–1997)	First experiment that exposed the violation of conservation of parity. Chien-Shiung Wu observed the beta emission from cobalt-60 (Co-60) at very low temperatures.
1957	Julian Schwinger (1918–1994), Sidney Bludman (1927–), Sheldon Lee Glashow (1933–), and Hideki Yukawa (1907–1981)	Bosons provide the weak attraction. Initially conceived by Hideki Yukawa (1907–1981) in 1937. These heavy bosons are referred to as W^- and W^+ .

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1957	John Bardeen (1908–1991), Leon N. Cooper (1930–) and John Robert Schrieffer (1931–)	First comprehensive theory of superconductivity. They all shared the Nobel Prize in Physics in 1972.
1958	Stanley Mandelstam (1928–)	Introduction of Mandelstam variables associated with the concept of “crossing symmetry,” defining numerical quantities which encode the energy, momentum, and scattering angles of particles in a deflection process described in a Lorentz invariant fashion
1958	Lev Davidovich Landau [Russian: Лёв Давидович Ландау] (1908–1968), Arkady Beynusovich Migdal [Russian: Аркадий Бейнусович (Бенедиктович) Мигдал] (1911–1991)	Theory of interacting electrons, specifically with respect to solids; condensed matter physics.
1958	Charles Hard Townes (1915–), John Perry Cedarholm (1927–), George Francis Bland (1927–2010), and Byron Luther Havens (1914–1989)	Experimental application of maser beams constructing the most precise ether-drift experiment yet. The results tentatively eluded to the fact that if the effect exists, it is less than one-thousandth of the earth’s orbital speed or less than one ten-millionth of the speed of light. The precision in the frequency comparison of the masers was about one part in a 10^{12} .
1958	Rudolph Ludwig Mössbauer (1929–2011)	Predicted and experimentally verified an extremely small frequency spread in the low-energy gamma emission from nuclei bound in a crystal lattice. This effect results from transferring the gamma ray recoil momentum to the whole lattice instead of to an individual nucleus. The Mössbauer effect provides a very high precision frequency standard which lends itself for verification of several predictions made with regard to the special and general theories of relativity. Rudolph Mossbauer shared the Nobel Prize in Physics jointly with Robert Hofstadter (1915–1990) in 1961.
1959	James Alfred Van Allen (1914–2006)	Obtained data from instruments hosted on artificial satellites and derived that the earth is encircled by two zones, referred to as “Van Allen” (radiation) belts. The Van Allen belts consist of high-energy charged particles that are harnessed by the earth’s magnetic field.
1960	Vernon Willard Hughes (1921–2003), Douglas W. McColm (1933?–), Klaus Otto Heinrich Ziock (1925–2010) and Richard Prepost (?–?)	Constructed and studied the atom muonium, a short-lived atom with a positive mu-meson as nucleus and a single orbiting electron.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1961	Murray Gell-Mann (1929–)	Description of elementary particles, eight-fold way of defining “strangeness” for the quark. Formal introduction of the elementary particle “quark” concept, the building blocks for protons and neutrons. The “quark” name is based on an expression in the book <i>Finnegans Wake</i> by James Joyce.
1962	Brian David Josephson (1940–)	Discovery and theoretically analyzation of a number of unexpected phenomena occurring at a “Josephson junction.” The Josephson junction represents an arrangement consisting of two superconductors that are separated by a very narrow layer of insulating material.
1964	Charles Hard Townes (1915–2015), Nikolay Gennadiyevich Basov [Никола́й Генна́диевич Ба́сов] (1922–2001) and Aleksandr Mikhailovich Prokhorov [Алекса́ндр Миха́йлович Про́хоров] (1916–2002)	Quantum electronics.
1965	Oscar Wallace Greenberg (1932–), Moo-Young Han (1934–), and Yoichiro Nambu [南部陽一郎] (1921–)	Introduction of the concept of “color” change as designation and property for quarks.
1965	George Claude Pimentel (1922–1989) and Jerome V. V. Kasper (??)	Construction of first chemical laser, laser action relying on pumping energy supported by chemical reactions, in contrast to an external source of power, generally irradiation.
1970	Sheldon Lee Glashow (1932–), John Iliopoulos (1940–), and Luciano Maiani (1941–)	Introduction of the charm quark.
1973	Hugh David Politzer (1949–), David Jonathan Gross (1941–), and Frank Anthony Wilczek (1951–2015)	Discovery associating the quark color theory of the strong interaction to a special property, referred to as “asymptotic freedom.” This “color” property is required to describe the data acquired over the prior period from 1968 to 1969 with respect to the substrate of the proton.
1974	Burton Richter (1931–) and Samuel Chao Chung Ting [Chinese: 丁肇中] (1936–)	Description of charm for the quark.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1975	Carlo Rubbia (1934–), Burton Richter (1931), Frederick Reines (1918–1998), Jack Steinberger (1921), Leon Lederman (1922–), Richard Taylor (1929–), Jerome Friedman (1930), and Martin Perl (1927–2014)	Standard model of particle interaction. Interactions between leptons and quarks, interacting by means of bosons. Listing the contributing scientist that led to the discovery of the various elementary particles, respectively: W and Z boson; charm quark; neutrino; muon–neutrino; muon–neutrino and b-quark; quarks (general); quarks (general); tau.
1975	Martin Lewis Perl (1927–2014)	Discovery of the tau lepton.
1977	Leon Max Ledderman (1922–)	Discovery of the “beauty” and “bottom” designation for quarks.
1978		Discovery of the “gluon” with the assistance of the PLUTO, the first electromagnetic superconductive solenoid located in Hamburg, Germany.
1983	Collider Detector at Fermilab	World’s first and at the time highest-energy particle accelerator, colliding antiprotons, and protons propelled to center-of-mass energy reaching 2 TeV.
1995	Wolfgang Ketterle (1957–), Eric Allin Cornell (1961–), and Carl Edwin Wieman (1951–)	Experimental verification of Bose–Einstein condensation.
2012	François Baron Englert (1932–) and Peter Ware Higgs (1929–)	Higgs boson (126 GeV) discovery in the Large Hadron Collider at CERN, Geneva, Switzerland. The Large Hadron Collider construction started in 1998 and produces particle acceleration with respective energy levels for protons at up to 4 teraelectronvolts (0.64 microjoules), or lead nuclei: 2.76 TeV per nucleon or 574 TeV per nucleus. The proton energy level was increased to 6.5 TeV in 2015.

Biomedical

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
2900 BC		Construction of artificial eyes by Egyptian priest, without any optical function. These eyes were for “decoration” only, called Ectblepharons, worn generally outside the eye socket made from painted clay or enameled metal.
3000–2500 BC	Imhotep (c. 2650–2600 BC)	Papyrus scrolls describing several traumas and additional surgical procedures, in addition to the medical diagnosis and procedures related to pregnancy. The biomedical relevance primarily relates to the mechanical nature. Some aspects of the description of embalming for mummification and the removal of the brain through the nose are still relevant with respect to performing brain surgery, also through the nose if possible. But no reference to the functional aspects of the brain are made. Cancer was recognized and described.
1600 BC		Documented anatomical drawings found in Egypt displaying a rudimentary physiological and fluid dynamics as well as electrophysiological purpose of the following items hypothalamus, liver, kidneys, spleen, uterus, and bladder were documented. For the heart, with adjoining vessels, it was obvious that they were recognized to emanate from the heart. The papyrus scrolls also describe several identified ailments and diseases next to fractures and means to mend these afflictions.
ca. 400 BC	Plato, also known as Aristotle (427–347 BC)	Early misconceptions regarding vision. Object supposedly emit “light” which in turn is captured by the eye.
ca. 350 BC	Aristotle (384–322 BC)	Proposed the concept of light emitted by a source, such as a candle or the Sun, which is subsequently reflected by objects and hence captured by the eye; providing the fundamental principle of sight.
ca. 300 BC	Euclid of Alexandria (ca. 350 BC–280 BC)	Publication of the treatise on light: “optics” (Ὀπτικά), describing the principles of the image formation, next to general vision aspects related to the eye.
ca. 170	Claudius Galenus (130–201)	Detailed description of the anatomy of the eye: lens, retina, and optic nerve; however, still supporting the “extramission” concept introduced by Plato.
ca. 200	Claudius Galenus (130–201)	Initial measurements of the lung volume. Galen also introduced early concept of ventilation.
800s	Yaqub ibn Ishaq al-Kindi (801–873) and Abu Zayd Hunayn ibn Ishaq al-Ibadi (808–873)	Reiteration of the erroneous concept of extramission for sight

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
~900	Mohammad ibn Zakariya al-Razi (864–930)	Realization of the fact that the diameter of the pupil of the eye responds to the magnitude of light finally revised the vision concept to that initially introduced by Aristotle using the external light sources as a means to support vision.
ca. 1000	Avicenna (980–1037)	Description of the power of locomotion with respect to the torque applied on joints resulting from muscular contraction. He also provided a rudimentary description of the pump function for the heart.
~1300	Henri de Mondeville (1260–1320)	Treatment attempt for smallpox using light.
1480	Leonardo da Vinci (1452–1519)	Leonardo da Vinci initially supported the erroneous extramission concept for vision, but finally rejected this based on his experimentation with image formation using an ox eye from which he had scraped the retina, providing a lens with “screen” that forms an image. Leonardo da Vinci also contributed significantly to the pictorial record keeping of muscle structures, types, and contraction mechanisms.
~1500		In-socket artificial eye development, still without a true optical function.
1535	Andrés de Laguna (1499–1559)	Detailed anatomical description with terminology describing the heart, consisting of two ventricles (announcing the “right” and “left” ventricle, as we currently know and use it) and two “auricles” as he referred to the atria.
1503	Gregor Reisch (1467–1525)	Detailed human anatomical drawings in the publication: <i>Margarita Philosophica</i> . The total works of Gregor Reisch form a series of 12 books compiling an encyclopedia describing topics ranging from Latin grammar, to dialectics, rhetoric, arithmetic, music, geometry, astronomy, physics, natural history, physiology, psychology, and ethics
1543	Andreas Vesalius (1514–1564)	Detailed description and graphic representation of the anatomy of the human body, circulation system, and rudimentary description of the function of several organs and their respective engineering and physics applications. Founder of the principles of modern anatomy.
1621	Willebrord Snell (1591–1626) and René Descartes (1596–1650)	Fundamental theoretical description supporting the concept of image formation by the lens of the eye based on the law of refraction.
1628	William Harvey (1578–1657)	Detailed functional description of the cardiovascular circulation, left heart for whole body and right heart to lungs. Referring to the observations and descriptions by Andrés de Laguna (1499–1559) a century prior.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1629	Réne Descartes (1596–1650)	Description of muscles, tendons, and some reference to external stimulation, as what we now know are nerve impulses. Confirming/underwriting the pump function of the heart muscle (cardiac muscle).
1653	William Harvey (1578–1657)	Detailed description of the actin and myosin fibers defining muscle contraction.
1681	Giovanni Alfonso Borelli (1608–1679)	Measurement of vital capacity and other volumetric data regarding respiration.
1750	Robert Whytt (1714–1766)	Description of the electrical stimulation of the “optic nerve” resulting from light reaching the retina. Although the nerve as a functional unit was not understood yet. The observations were primarily derived from follow-up responses (e.g., muscle contraction) produced by the individual in the experimental set-up.
	Emanuel Swedenborg (1688–1772)	Realization that the brain is the central processing unit for nerve impulses and motor control. Published posthumously. Unfortunately, his efforts were not recognized until the year 1887.
1776	Luigi Galvani (1737–1789)	Biomedical connection to electricity and development of a mechanism to measure electrical energy
1781	Felice Gaspar Ferdinand Fontana (1730–1805)	Description of the functional aspects of the nerve fiber, but not including the phenomenological description. The description was based on the elaboration of the “electric fish” (eel) by John Walsh (1725–1795) and the work of electrical interactions with the human body by Luigi Galvani (1737–1798). The electricity of the eel was known for millennia, but not understood.
1812	Julien Jean César Legallois (1770–1814)	Recognition of the part of the brain regulation respiration (medulla). Also described the fact that gas exchanges between blood and the cells changes the partial pressure of elements in the blood with respect to the surrounding tissues, the supply of oxygen to support the metabolism and the secretion of waste carbon dioxide. His ideas also introduced the use of external supply of arterial blood to extend life, but this was not implemented until much later.
1841	Claude Bernard (1813–1878)	Recognition of the chemical equilibrium supporting life and functionality of the cell (homeostasis).
1824	Félix Savart (1791–1841)	Description of the motion of the Tympanic membrane inside the inner ear (cochlea) under the influence of applied sound.
1826	Johannes Peter Müller (1801–1858)	Description of nerve impulses, and that a nerve will produce only one particular sensation, irrespective of the stimulus. This ties to the fact that the brain interprets the stimulus, which was not known at that time in detail.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
~1844	Ludwig Feuerbach (1804–1872)	Description of the five individual senses: sight/vision, hearing, touch, taste, and smell, in addition to more derived sensations such as thought, love, and experience.
1849	John Hutchinson (1811–1861)	Description of the mechanism of tidal breathing relating the pressure in the lung (alveoli) to the volume of the different stages of respiration. This work relates directly to the theoretical description by Pierre-Simon Laplace (1749–1827).
1849	Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Description of electrical stimulation resulting in muscle contraction. The decryption included a rudimentary reference to the concept of the action potential, which was at the time not known.
1855	Adolf Eugen Fick (1829–1901)	Fick's diffusion equation for gases and dissolved chemical constituents with respect to membranes.
1857	Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Theoretical description of hearing based on the (misplaced) assumptions of the basilar membrane within the cochlea acting as a resonating structure. In this resonance cavity model the low-frequency tones activating the membrane from the apical turn and high-frequency tones activating it from the basal turn. This was later corrected by the work of Georg von Békésy (1899–1972). There are also indications placing these statement at an earlier date (other contributing persons, for instance his teacher: Johannes Müller [1801–1858]).
~1860		Replacement lenses to facilitate artificial eyes reconstruction is making a functional introduction. Small ocular lenses were blown with relatively high-quality glass, initiated in Germany.
1864	Adam Politzer (1835–1920)	Description of the movement of the ossicles in the middle ear under the influence of sound. This was another step into the understanding of the auditory functioning.
1864	Wilhelm Kühne (1837–1900)	Defined the term “myosin” as a molecular component in the contractile mechanism of action for muscle. Not by long a full description of the functional aspect for the muscle since the remaining components were not discovered until 1942 and later.
1868	Julius Bernstein (1839–1917)	Introduction to the formal mechanism of action for the action potential.
1870	Adolf Eugen Fick (1829–1901)	First recorded measurement of cardiac output; using the Fick principle.
1875	Richard Caton (1842–1926) [Lord Mayor of Liverpool]	Recognized electrical activity of the brain; initial indication for the recording of the electro encephalogram (EEG). Richard Caton contributed to the general understanding of the electrophysiology concepts.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
~1890	Niels Ryberg Finsen (1860–1904)	Successful treatment of smallpox with light, building on the early work of Henri de Mondeville (1260–1320).
1888–1889	Walter Nernst (1864–1941)	Definition of the electrochemical potential across a cellular membrane due to the gradient in chemical concentration for several elements. This process produces a “half-cell potential,” similar to what is found in batteries. This can be placed in perspective to the first “battery” that is practical in use, designed by Alessandro Giuseppe Antonio Anastasio Volta (1745–1827) in 1800.
~1900	Oscar Raab (1876?–1986) and Giorgio Marcacci (18??–19??)	Discovery of the phototoxicity of light, specifically in the eradication of cancer.
1901	Willem Einthoven (1860–1927)	Invention of the first user friendly and reproducible electrocardiogram recorder (ECG, also found as EKG) pertaining to the electrical excitation for the contractility of the respective (cardiac-) muscle compartments of the hearts. Willem Einthoven used sting galvanometers of his own design. This provided an essential contribution to the understanding of cardiac arrhythmias and heart problems including the resulting fluid-dynamic results from the whole cardiovascular system.
1905	Nikolai Korotkoff (1874–1920)	Discovery of the sounds produced by arterial blood flowing through the brachial artery. When compressing the brachial artery the flow is interrupted, until the applied pressure is slowly dropped to the point where it matches the systolic pressure, producing an intermitted sound train, progressing in a steady rush when the applied pressure is dropped further to become equal to the diastolic pressure. Korotkoff sounds provide a noninvasive mechanism to determine blood pressure, used in every day medical applications with the aid of a stethoscope and an inflatable armband.
1911	Josiah Willard Gibbs (1839–1903); Frederick George Donnan (1870–1956)	Gibbs–Donnan equilibrium for transmembrane electrolytic solutions.
1914–1918		Mapping of brain function with respect to encephalographic location on soldiers while they are still alive with brain tissue exposed (resulting from explosives) in the trenches during World-War I.
1924	Hans Berger (1873–1941)	First official recording of brain activity by means of an electro-encephalogram (EEG). This recording provided a breakthrough in neurologic investigations and the integration of stimulus and response with respect to the respective central and peripheral nervous systems.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1926	Mark Cowley Lidwell (1878–1969) and Edgar Harold Booth (1893–1963)	Rudimentary, but effective, external cardiac pacemaker design.
1929	Otfrid Foerster (1873–1941)	Recognition of the stimulation of the occipital cortex for processing of images acquired by the eye.
1942	Brunó Ferenc Straub (1914–1996)	Description of the “actin” molecule as an integral part to the muscular mechanism of action. As a counterpart to myosin, discovered in 1864. Further refinements were introduced in 1957.
1950	John Alexander Hopps (1919–1998)	Introduction of the “portable” (45 kg) cardiac pacemaker, based on the earlier work by Mark Lidwell (1878–1969) and Edgar Harold Booth (1893–1963) in 1926. This led, with the development of microprocessors, to the first implantable pacemaker in 1958 by William Chardack (1919–2011) and Wilson Greatbatch (1919–2011) in 1958.
1953	Rosalind Elsie Franklin (1920–1958)	Discovery of the macromolecular structure (double helix) and configuration for deoxyribonucleic acid (DNA), as well as contributions to the chemical molecular description of RNA (ribonucleic acid), viruses, coal, and graphite. Rosalind Franklin used X-ray diffraction techniques for her analysis.
1956	Paul Winchell {Wilchinsky} (1922–2005)	Artificial heart (Jarvik 7).
1952		First mechanical blood pump used to assist in open-heart surgery.
1954	Andrew Fielding Huxley (1917–2012) and Alan Lloyd Hodgkin (1914–1998)	Mathematical description of nerve impulses with great accuracy, based on the (steady-state) membrane potential described by Walter Nernst (1864–1941).
~1954	Georg von Békésy (1899–1972)	Fundamental description of the mechanism of action in human hearing.
1954	David E. Goldman (1910–1998)	Goldman equation, describing the membrane potential accounting for the free migration of ions through the cell membrane, adding to the Hodgkin–Huxley equation (Andrew Fielding Huxley [1917–2012] and Alan Lloyd Hodgkin [1914–1998]).
~1955	Willem Johan Kolff (1911–2009)	First commercial artificial kidney; hemodialysis. The design was based on principles introduced by Thomas Graham (1805–1869) in 1854, next to the theoretical chemistry influences of Adolf Fick (1829–1901).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1957	Hugh Esmor Huxley (1924–2013)	Discovery of the integral motion activity of muscular contraction with the assistance of electron microscopy imaging.
1966	Michael E. DeBakey [Michel Dabaghi] (1908–2008)	First left-ventricular assist device implanted in a human.
1968	Viking Olov Björk (1918–2009) and Donald Pearce Shiley (1920–2010)	Introduction of the tilting disk replacement heart valve prostatic.
1968	Giles Skey Brindley (1926–) and Walpole Sinclair Lewin (1915–1980)	Initial implementation of experimental artificial vision using electronic imaging devices, preceding the retinal implant approved in 2013. This work was based on the pioneering efforts by Otfried Foerster (1873–1941).
1981	Uri Dinnar (1939–2014)	Detailed theoretical description of the turbulent flow of cardiovascular fluid dynamics.
1982	Willem Johan Kolff (1911–2009) and Robert Koffler Jarvik (1946–)	First wearable artificial heart; “Jarvik heart.”
1997	Nathan S. Lewis (1956?–)	development of an electronic “nose,” resembling the human olfactory receptor system.
2001	Second Sight Inc.	First experimental artificial eye as a portable system, using a computer interface to the occipital lobe of the brain: ARGUS device.
2013		First FDA-approved retinal implant for regaining vision.

Chemical

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
“Ancient man”		Realization that the following chemical compounds were pure; what we currently consider as elements: gold (8000 BC), silver (<5000 BC), iron (<5000 BC), copper (9000 BC), mercury (<2000 BC), tin (~3500 BC), carbon (3750 BC), and sulfur (2000 BC). Element: a substance consisting of atoms with associated same number of protons (identical atomic number). Elements are the simplest chemical substances, which cannot be broken down further by means of chemical methods. Elements can be converted into other elements only using nuclear methods.
1700 BC	King Hammurabi’s reign over Babylon	Known metals were documented and listed in relation to heavenly bodies.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 600 BC	Thales of Miletus (ca 624 BC–ca 546 BC; known as Thales: Θαλής)	First person to question the basic principles that is documented as such (by Aristotle [384 BC–322 BC]), and specifically the originating substances of matter. Considered the founder of the school of natural philosophy.
450 BC	Leucippus (fifth century BC)	Argued that the universe consists as a structure of atoms and voids.
430 BC	Democritus (of Greece) (460 BC–370 BC)	Proclamation that the atom is the smallest and simplest unit of all matter. All matter is composed of atoms. The first rudimentary introduction of the elementary build block but with no scientific support. Greek word “atomos” (ἄτομος), meaning indivisible.
350 BC	Aristotle (384 BC–322 BC)	Declaration of only four (4) elements defining the existence on earth: fire, water, air, and earth. Matter only has the following properties: wet, dry, hot, or cold.
300	Alchemists	Based on the philosophy of Aristotle, the alchemists believed that “regular” metals could be converted into precious metal, specifically gold, a wishful thought. The item required to perform this conversion was referred to as the elusive “philosopher’s stone.”
“Dark Ages” 500–1300		
1615	Jean Beguin (1550–1620)	First diagram expression for a chemical reaction in a notation that we adhere to today.
1661	Robert Boyle (1627–1691)	End of the era of the Alchemists (perpetuated for 2000 years), partially based on the book by Robert Boyle, <i>The Skeptical Chymist</i> . First “modern chemist.”
1669	Henning Brand (1630–1710)	Documented observation that phosphorus is an element.
~1650–1750	Jöns Jacob Berzelius (1779–1848), John Dalton (1766–1844), and Antoine Lavoisier (1743–1794)	Beginnings of “modern chemistry” indicated by the group of scientists considered the “fathers of modern chemistry.”
ca. 1670	Sir Isaac Newton (1643–1727)	Sir Isaac Newton was one of the prominent proponents and advocates of the atom theory.
1757	William Cullen (1710–1790)	Introduction of the first formula for a chemical reaction.
1774	Antoine Lavoisier (1743–1794)	Discovery of oxygen; and the chemical process of oxidation.
1785	Charles Augustin de Coulomb (1736–1806)	Treatise on electricity: <i>Premier Mémoire sur l’Électricité et le Magnétisme</i> . The unit of electric charge is named after him posthumously. The free electric charge is the electron, which was not fully understood, nor described. The electron does form the basis for strong chemical connections, based on ion formation.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1789	William Higgins (1763–1825)	First use of the term molecule describing a chemical compound consisting of multiple atoms. The word molecule can be traced back to 1678. The expression and concept of the molecule has ties to Rene Descartes (1596–1650) and Robert Boyle (1627–1991).
ca. 1800	John Dalton (1766–1844)	Introduction of the “law of multiple proportions” describing the atomic concept based on chemical reactions taking place in ratios of small whole numbers.
1806	Sir Humphry Davy, 1st Baronet (1778–1829)	Discovery of several alkali next to alkaline earth metals, as well as contributions to the description and discovery of the elemental nature of the elements chlorine and iodine
1810	Joseph Louis Gay-Lussac (1778–1850)	Gas laws and the means to determine the alcohol content of a liquid, still used. Alcohol by volume is referenced as degrees Gay-Lussac in certain countries.
1811	Lorenzo Romano Amedeo Carlo Avogadro di Quaregna e di Cerreto, Count of Quaregna and Cerreto (1776–1856)	Molecular arrangements; molecular quantity in a mole of substance. Avogadro’s law.
1820	Pierre Louis Dulong (1785–1838) and Alexis-Thérèse Petit (1791–1820)	Dulong and Petit law of specific heats.
1841	Claude Bernard (1813–1878)	Recognition of the chemical equilibrium supporting life and functionality of the cell (homeostasis).
1855	Adolf Eugen Fick (1829–1901)	Fick’s diffusion equation for gases and dissolved chemical constituents with respect to membranes.
1857	Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Introduction of chemical thermodynamics concepts and definitions and electrodynamics. Hermann von Helmholtz also worked on sensory physiology, inspired by the work of Wilhelm Wundt (1832–1920). He also worked on the functional nerve physiology.
1864	Wilhelm Kühne (1837–1900)	Defined the term “myosin” as a molecular component in the contractile mechanism of action for muscle. Not by long a full description of the functional aspect for the muscle since the remaining components were not discovered until 1942 and later.
1868	Julius Bernstein (1839–1917)	Introduction to the formal mechanism of action for the action potential.
1860	Stanislao Cannizzaro (1826–1910)	Cannizzaro reaction.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1869	Dmitri Ivanovich Mendeleev (1834–1907) and Julius Lothar Meyer (1830–1895)	Both independently introduced the Periodic Table of the Elements, a concise summary of years of documented experimental and theoretical chemistry. The table is both heuristic and mnemonic.
1873	Josiah Willard Gibbs (1839–1903)	Chemical potential, a energy constituent within the Gibbs free energy. Thermodynamic concept describing the energy that can be released or absorbed during a chemical reaction.
1874	Jacobus Henricus van 't Hoff (1852–1911) and Joseph Achille Le Bel (1847–1930)	Two independent observations regarding the optical activity (rotation of polarization direction for transmitted light) for carbon compounds. They both derived that this can be explained by a four (4) way bound carbon atom (chemical saturation).
1879	William Crookes (1832–1919)	Cathode rays and realization that single charged particles must be involved.
1885	Eugene Goldstein (1850–1930)	Discovery of the proton.
1880	Paul-Jacques Curie (1855–1941) and Pierre Curie (1859–1906)	Discovery of electric charges emerging on the surfaces of crystals, which are subjected to shear or normal stress. This is referred to as the piezoelectric effect.
1880	Johannes Diderik van der Waals (1837–1923)	Description of the covalent bond. Van der Waals equation.
1897	Joseph John Thomson (1856–1940)	Discovery of the electron concept; using William Crookes's vacuum tube. The electron itself was at this point not identified.
1897	Marie Skłodowska Curie (1867–1934)	Discovery of radioactive isotopes.
~1890	Niels Ryberg Finsen (1860–1904)	Successful treatment of smallpox with light, building on the early work of Henri de Mondeville (1260–1320).
1888–1889	Walter Nernst (1864–1941)	Definition of the electrochemical potential across a cellular membrane due to the gradient in chemical concentration for several elements. This process produces a “half-cell potential,” similar to what is found in batteries. This can be placed in perspective to the first “battery” that is practical in use, designed by Alessandro Giuseppe Antonio Anastasio Volta (1745–1827) in 1800.
~1900	Oscar Raab (1876?–1986) and Giorgio Marcacci (18??–19??)	Discovery of the phototoxicity of light, specifically in the eradication of cancer.
1906	Dmitri Ivanovich Mendeleev (1834–1907)	Periodic Table of Elements.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1911	Josiah Willard Gibbs (1839–1903) and Frederick George Donnan (1870–1956)	Gibbs–Donnan equilibrium for transmembrane electrolytic solutions.
1909	Robert Andrews Millikan (1868–1953)	Measurement of the mass of the electron.
1914	Henry Gwyn Jeffrey Moseley (1884–1915)	X-ray spectrograms of the elements which assisted in the establishment of the identity of the ordinal number of respective elements in the periodic table associated with its nuclear charge: atomic number.
1916	Niels Henrik David Bohr (1885–1962)	Atomic structure and quantum theory.
1916	Gilbert Newton Lewis (1875–1946)	Description of the shell filling for atomic electrons, and the related covalent bond and the concept of valence electrons.
1917	Ernest Rutherford, 1st Baron Rutherford of Nelson (1871–1937)	Discovery of the proton.
1926	1928: Paul Dirac (1902–1984); 1929: Dmitri Vladimirovich Skobeltsyn (1892–1990); and 1932: Carl David Anderson (1905–1991)	Discovery of positron. Generally, Carl Anderson is credited with the formal discovery (Nobel Prize).
1926	Jean Baptiste Perrin (1870–1942)	Physical proof providing the existence of molecules.
1927	Wolfgang Ernst Pauli (1900–1958), Ralph Kronig (1904–1995), George Eugene Uhlenbeck (1900–1988), Samuel Abraham Goudsmit (1902–1978), and Paul Adrien Maurice Dirac (1902–1984)	Introduction of the electron spin concept and a broad range of relativistic quantum mechanical principles. This formed the foundation for the development of the NMR imaging system: nuclear magnetic resonance (MRI).
1928	Sir Chandrasekhara Venkata Raman (1888–1970)	Raman spectroscopy; indicating the energy levels in atoms and molecules.
1931	Linus Carl Pauling (1901–1994)	Description of the general and detailed nature of various types of chemical bonds.
1932	James Chadwick (1891–1974)	Discovery of the neutron.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1940+	Julius Robert Oppenheimer (1904–1967)	Manhattan project: fission reaction. Prominent members: Arthur Compton (1892–1962), Enrico Fermi (1901–1954), Eugene Wigner (1902–1995), and dozens more.
1924	Niels Henrik David Bohr (1885–1962)	Introduction of the term: “element.” This idea was formed based on Wolfgang Pauli’s (1900–1958) exclusion principle. The element concept has been around for millennia.
1950	Maria Goeppert-Mayer (Göppert) (1906–1972)	Introduction of the nuclear shell model of atomic nuclei.
1953	Rosalind Elsie Franklin (1920–1958)	Discovery of the macromolecular structure (double helix) and configuration for deoxyribonucleic acid (DNA), as well as contributions to the chemical molecular description of RNA (ribonucleic acid), viruses, coal, and graphite.
~1955	Willem Johan Kolff (1911–2009)	First commercial artificial kidney; hemodialysis. The design was based on principles introduced by Thomas Graham (1805–1869) in 1854, next to the theoretical chemistry influences of Adolf Fick (1829–1901).
1992	Kenneth Kin Man Kwong (1948–)	Introduction of “functional MRI.” In 2013 the sugar consumption was measured in cancer cells with respect to normal cells for diagnostic verification.

Computational

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
9000 BC–6500 BC	Ishango Bone	Bone with the first prime numbers carved in order.
3500 BC	Mesopotamian clay tablets	Clay carvings with geometrical shapes, fractions, and logarithm and a list of “squares.” Most was published on a base of 60, not our current 10-base
1600 BC	Rhind papyrus	Papyrus scrolls with mathematical equations and fractions.
1750 BC–500 BC	Vedic period (India)	Advanced civilization with a great number of mathematical revelations. Algebra, trigonometry, and geometry expression by Lagadha, approx. 1300 BC; approx. 800 BC and Yajnavalkya also approx. 800 BC.
600 BC	Apastambha (ca. 630–560 BC)	Hindu (India) scholar that expressed the value of pi (π) well before the documented use in the Egyptian/ Babylonian mathematics. This relates to the calculations of the circumference and area of circle and sphere. Apastambha may have described the angular concepts that are attributed to Pythagoras at least a century prior.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
600 BC	Thales of Miletus (ca. 640 BC–546 BC)	First introduction to finite (differential) approximation. Father of philosophy. Also described the use of triangulation to measure dimensions of remote objects (i.e., height of pyramids). Greek philosopher who supposedly studied under the Egyptians (Mesopotamia).
530 BC	Pythagoras of Samos (ca. 578–505 BC)	Student of a student of Thales. Introduced the formal concepts in geometry.
450 BC	Zeno of Elea (ca. 495–435 BC)	Introduced the concept of infinitesimal steps (infinitesimally small; approach of a turtle that is moving away, paradox).
350 BC	Aristotle [of Stagira] (384–322 BC)	Teacher to Euclid. Documented axioms and proofs. Introduced the initial concepts of the wave theory for light, although not accepted for almost 2000 years.
300 BC	Euclid [of Megara and Alexandria] (ca. 322–275 BC)	“Father of modern mathematics.” Introduced the Euclidean space for model formation representing real-life situations. He described spherical geometry and other complex geometrical forms such as the cone.
250 BC	Archimedes of Syracuse (287 BC–212 BC)	Student at the school of Euclid, most likely after Euclid’s death. number theory, and square roots. Additional mathematics applied to specific physical phenomena such as buoyancy.
ca. 130	Claudius Ptolemaeus of Alexandria (ca. 90–168)	Introduction of various mathematical rules and theorems that allowed the introduction of more complex mathematics as seen in the following centuries. Ptolemy’s theorem.
ca. 250	Liu Hui (ca. 220–280) [China]	Incorporation of negative numbers in mathematical expressions and arithmetic. Building on the work of Chang Tshang (ca. 200–142 BC) also from China. Liu Hui is considered to be one of China’s greatest mathematicians. He also formalized the decimal system. The number zero had a special meaning, introducing the initial concept of the “singularity.” Hui also described the process for solving a series of linear equations (solving for multiple unknowns).
ca. 500	Aryabhata (476–550) [India]	Advanced mathematics, including series resembling the “Taylor series.”
ca. 850	Ya’qub ‘Abu Yusuf’ ibn Ishaq al-Kindi (803–873) [Iraq]; Al-Kindi referred to as Alkindus in the West	Popularized the implementation of the decimal system, developed spherical geometry, and many other science and engineering topics and pioneered the concept of cryptography (code breaking). (Al-Kindi, called the Arab Philosopher, however not one of the greatest of mathematicians, but was one of the most influential scientists between Aristotle (384 BC–322 BC) and Leonardo da Vinci (1452–1519).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 1000	Mohammed ibn al-Hasn (Alhazen) 'Abu Ali' ibn al-Haytham al-Basra (965–1039) [Iraq, Egypt]	Mathematical descriptions in optics and astronomy. The work of Al Hazen anticipated Newton's first law of motion (Sir Isaac Newton [1643–1727]); the "principle of least action."
ca. 1200	Leonardo 'Bigollo' Pisano (Fibonacci) (ca. 1170–1245) [Italy]	Known today as "Fibonacci." Provided the persuasion for Europe to the decimal system, also using fractions. Defined congruous in addition to the theorems to provide the supporting proof. The work of Fibonacci has great relevance in biomedical applications, if not alone the Fibonacci code found for instance in the "veins" in a leaf of a tree.
1202	Leonardo Fibonacci (1170–1240) [Leonardo Bonacci/Leonardo of Pisa, Leonardo Pisano Bigollo]	First lecture text on algebra; introduction of the Fibonacci sequence, found in several natural phenomena.
ca. 1320	Levi ben Gerson 'Gersonides' (1288–1344?)	Various basic scientific advancement resulted from his mathematical efforts. One specific example is the realization that in musical notes there are no consecutive harmonic numbers larger than (8, resp. 9).
1475	Luca Pacioli (1445–1572)	Collaborator with (mentor to) Leonardo da Vinci (1452–1519). Published work on geometry (in particular perspective), and accounting. One specific work on the Euclidean mathematics was a great step forward in conceptual mathematics.
1500	Leonardo da Vinci (1452–1519)	Renaissance man. Formal description of physical phenomena based on the state-of-the-art mathematical definitions, inventor, and prolific writer.
ca. 1500	Nicolaus Copernicus (1472–1543)	Astronomy and cartography. Telescope design and construction and associated calculations of the locations of observations on stars and planetary movements.
1575	Simon Stevin (1549–1620)	Civil engineering supported by stringent mathematical calculations. Windmill design, working as an engineering architect. Simon Stevin introduced the real number concept and the square root sign. Formally introduced the formal concept of decimal system in western Europe. Predated some observation and conclusion attributed to Augustin-Louis Cauchy (1789–1857).
ca. 1600	John Napier 8th of Merchistoun (1550–1617)	Formal introduction of the logarithm concept. Inventor of a rudimentary but pioneering calculator, next to the abacus.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 1600	Galileo Galilei (1564–1642)	Described laws of motion (falling bodies; gravitational acceleration) and inertia, before Sir Isaac Newton (1643–1727). Invented the pendulum clock and many more engineering feats. Additional contributions by Galileo Galilei are in astronomy, specifically the discovery of Jupiter’s moons. Galileo also wrote about infinite equinumerosity, what is known as the “Hilbert’s Hotel Paradox” (David Hilbert [1862–1943]; ‘Hilbert Space’). Galileo once wrote “Mathematics is the language in which God has written the universe.”
ca. 1600		Acceptance of the decimal system in Europe. Early evidence of the decimal system dates as far back as 3000 BC China (used in the abacus). Furthermore, the Greek mathematicians also used the decimal system. (Northern) Europe prior to this used a system based on halves, still in use in the United States of America.
ca. 1600	Johannes Kepler (1571–1630)	As the understudy to Tycho Brahe (1546–1601) {Tyge Ottesen Brahe} Johannes Kepler used the astronomical data collected by Tycho Brahe to develop a detailed calculation for the planetary motion based on his derived elliptical orbits in contrast to the up to that time assumed circular orbits.
ca 1620	René Descartes (1596–1650)	Description of Euler’s (Leonard Euler [1707–1783]) polyhedral theorem, pre-dating Euler. Description of a “vortex” theory for gravitation, next to various laws of motion.
ca. 1625	Francesco Bonaventura de Cavalieri (1598–1647)	Worked in optics and astronomy and proposed several limit series (theorems) for known algebraic problems, often based on his trigonometry interests. In specific he described the area for a spherical triangle.
1647	Bonaventura Francesco Cavalieri (1598–1647)	Derivation of the relationship between the radii of curvature for the respective two surfaces of a thin lens and the resulting focal length.
ca. 1650	Pierre de Fermat (1601–1665)	Developed infinitesimal (elementary) calculus. Instrumental in the development of the mathematical description of the optical refraction principle. Several of Fermat’s efforts extended beyond the two-dimensional plane where most mathematicians were comfortable.
ca. 1650	Gilles Personne de Roberval (1602–1675)	Developed the initial principles for integration, basing his work on the publications from Archimedes (287 BC–212 BC), rather than on Francesco Bonaventura de Cavalieri (1598–1647). Roberval was instrumental in the development of cartography. Gilles de Roberval also worked alongside Blaise Pascal (1623–1662) on several experiments.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 1650	Blaise Pascal (1623–1662)	Designed several calculator machines. Worked on pressure and introduced “the scientific method.” Corresponded with Pierre de Fermat (1601–1665) on his ideas about probability and geometry. He also followed the work of Evangelista Torricelli (1608–1647) closely.
ca. 1650	Christiaan Huygens (1629–1695)	Developed the inverse square law of gravitation (before Sir Isaac Newton [1643–1727]) and various mechanical devices, including a reliable pendulum, leading to an accurate time-keeping mechanism. The Huygens’ principle was a mathematical essay on the wave properties of light, still overpowered by the corpuscular interpretation by Sir Isaac Newton.
1665	James Gregory (1638–1675)	Inventor and designer of a reflecting telescope. Furthermore, Gregory developed several mathematical expressions, including a series expression for the inverted tangent. James Gregory anticipated the Cauchy convergence requirement in his analysis (Baron Augustin-Louis Cauchy [1789–1857]).
ca. 1670	Sir Isaac Newton (1643–1727)	Introduced revolutionary advances in optics, mechanics, thermodynamics, and acoustics and astronomy-based mechanics (astrophysics). Newton also developed a series to define the “arcsin” function. Sir Isaac Newton is most known for his formal introduction of the gravity concept, but had earlier work to build on at his disposal. Isaac Newton was one of the prominent proponents and advocates of the atom theory. Newton also introduced one of the first colour–hue wheels. Sir Newton was a master at geometry, solving several problems that were so far unsolved. In 1687 Sir Isaac Newton published: <i>Philosophiae Naturalis Principia Mathematica</i> .
1675	Gottfried Wilhelm von Leibniz (1646–1716)	Formal introduction to the calculus concepts. Leibniz discovered and proved a very effective identity series for pi (π): $\pi/4 = 1 - 1/3 + 1/5 - 1/7 + 1/9 - \dots$. Additionally, Leibniz introduced the mathematical notations that are still used to date.
1684	Jacob Bernoulli (1654–1705)	Developed integral and differential equations. Worked on fluid dynamics. Close friend of Gottfried Wilhelm von Leibniz (1646–1716). Older brother to Johann Bernoulli (1667–1748).
1700	Abraham De Moivre (1667–1754)	Contributed significantly to the development of probability theory, with close ties to Pierre Simon Laplace (1749–1827), following in his footsteps.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1700	Johann Bernoulli (1667–1748)	Johann learned from his older brother Jacob Bernoulli (1654–1705), and from Gottfried Wilhelm von Leibniz (1646–1716), and became a tutor to Leonhard Euler (1707–1783). Johann Bernoulli's son, Daniel Bernoulli (1700–1782) was just as much a polymath as his father and grandfather, next to his contributions to the description of gas dynamics: "Bernoulli's Law."
1715	Brook Taylor (1685–1731)	Rudimentary description and discovery of the Taylor Series described by the Scottish mathematician James Gregory (1638–1675) and later introduced formally by the English mathematician Brook Taylor (1685–1731).
1740	Daniel Bernoulli (1700–1782)	Son of Johann Bernoulli (1667–1748). He developed partial differential equation and used the "Fourier series" prior to the publication by Jean-Baptiste Joseph Fourier (1768–1830). The work of Daniel Bernoulli that he is most known for is in fluid dynamics and gas mechanics.
1750	Leonhard Euler (1707–1783)	Most prolific mathematician in the known history of mathematics. Euler developed the polyhedral theorem (with some suspicion that this may be traced back to René Descartes (1596–1650). Euler revolutionized the design of pumps based on his fluid dynamic theories, including turbine equations. Other theoretical interests of Leonhard Euler were optics, astronomy, acoustics, mechanics, and music. In his astrophysics work he developed a formulation to determine the moon orbit in a three body motion problem; first ever. Additional theoretical efforts defined the rotational motion of rigid bodies of various configurations. Euler also introduced the definition for the square root of negative one as the letter i , next to several other mathematical standard expressions for algebraic terms. Leonard Euler also introduced the exponential expression with the use of the complex number by means of sin and cosine: $e^{ix} = \cos x + i \sin x$. Euler popularized the use of the letter sigma for a series summation.
1760	Jean le Rond d' Alembert (1717–1783)	d'Alembert laid the foundation for modern meteorology with his mathematical descriptions of the formation of wind. Other work include collision dynamics, hydrodynamics, and vibration. Jean d' Alembert proved that every polynomial has a complex root (d' Alembert–Gauss theorem). Jean le Rond d' Alembert may have been the first person to express time as the fourth dimension, especially with respect to the complex physics phenomena evolving.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1760	Johann Heinrich Lambert (1727–1777)	Even after dropping out of school due to family circumstances at the age of 12, Johann Lambert became a renowned and influential mathematician. Johann Lambert made great contributions to astrophysics calculations, illustrating the existence of star clusters. Lambert also build the first operational photometer. In addition, on a geophysics level he contributed to the cartography and land movement dynamics.
1780	Joseph-Louis (Comte de) Lagrange (1736–1813) [Giuseppe Lodovico Lagrangia]	Introduced a range of polynomials, and introduced “group theory.” The use of transforms for functions in order to facilitate solving them was introduced before (or in conjunction with) Pierre Simon, Marquis de Laplace (1749–1827). Lagrange introduced the use of comma notations for first and second order derivative.
1799	Pierre Simon, marquis de Laplace (1749–1827)	Laplace Law; Laplace transform to solve complex equations and his work on celestial mechanics (astrophysics). The Laplace transform converts a temporal function into a frequency domain function.
1800	Adrien Marie Legendre (1752–1833)	Introduced the Legendre polynomials concepts and Legendre transform to aid in solving complex equations by conversion of spatial parameters. Legendre worked on spherical geometry. Legendre made significant advances in the solution technique applied to elliptic integrals.
1800	Jean Baptiste Joseph Fourier (1768–1830)	The Fourier transform is one of the most widely used mathematical tools in all fields of physics and engineering; converting any periodic or instantaneous event into a series (superposition) of sin and cosine terms, mathematical solving technique using increasing orders of perturbation. The Fourier transform has many trades of the Laplace transform, referring to the time to frequency conversion. In thermodynamics, Fourier introduced his heat equation that provides significant practical applications.
1808	Étienne-Louis Malus (1775–1812)	Mathematical analysis of the concept of light. Verified the principles introduced by Christiaan Huygens (1629–1695). Observed the light reflecting from the windows, uncovering an effect that was later attributed to the polarization of light resulting from reflection. Member of the mathematics section of the Institut d’Égypte resulting from his travels with Napoléon Bonaparte (1769–1821). Introduction of Malus’ law.
1810	Johann Carl Friedrich Gauss [Gauß] (1777–1855)	Gauss constructed the theory of complex numbers in the form we use today. In astrophysics Gauss derived the orbit of an asteroid (Ceres), observed during his life-time, and predicted its return path around the Sun with great accuracy. Carl Friedrich Gauss is most known for his practical contributions to the field of electricity and magnetism: Gauss’s law; magnetic flux theorem.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1810	Siméon Denis Poisson (1781–1840)	Poisson's analysis of the wave theory of light contributed to the evolution and understanding of interference principles and applications.
1820	William George Horner (1786–1837)	Introduction of the methodology for solving and calculating polynomials (roots): Horner's method. The methods were actually already described 600 years prior by the Chinese mathematician Qin Jiushao (秦九韶) (ca. 1202–1261).
ca. 1825	Baron Augustin-Louis Cauchy (1789–1857)	Pioneer in mathematical and structural analysis of data. Formally introduced several of the modern concepts of calculus. Cauchy also introduced the concept of convergent series, in order to obtain a finite solution.
1840	Carl Gustav Jacob Jacobi (1804–1851)	His work involved the development of what is known as cubic reciprocity, which was found very helpful by Carl Friedrich Gauss (1777–1855). Jacobi also worked closely with Sir William Rowan Hamilton (1805–1865), and he developed his own mathematical approach, the Jacobian matrix and determinants in vector calculus used to solve multiple co-dependent relations in multiple equations; specifically applied to partial derivatives. The Jacobian applies primarily to individual points in data space.
1840	Johann Peter Gustav Lejeune Dirichlet (1805–1859)	Dirichlet interpreted the work of Carl Friedrich Gauss (1777–1855), revealing various uncovered items. Gustav Dirichlet was a tutor, respectively mentor, to Sir William Rowan Hamilton (1805–1865), Bernhard Riemann (1826–1866) and Leopold Kronecker (1823–1891).
1842, 1851	Sir George Gabriel Stokes, 1st Baronet (1819–1903)	Fluid dynamics Stokes equation, aberration of light with respect to the wave properties of light. Additional work of Gabriel Stokes was in the initial full theoretical description of polarization of electromagnetic radiation.
1850	Sir William Rowan Hamilton (1805–1865)	Sir Hamilton is most known for his reformulation of Newtonian mechanics: Hamilton mechanics. Hamilton mechanics can be considered an essential building block to the development of quantum mechanics. Sir William Hamilton introduced the principles leading to the formulation of the Hamiltonian operator used in quantum mechanics, defining the total energy of a system.
1850	George Boole (1815–1864)	Known for the Boolean algebra and logic. The work of George Boole inspired Claude Shannon (1916–2001).
1860	Georg Friedrich Bernhard Riemann (1826–1866)	The work of Bernhard Riemann was instrumental in the development of the theory of general relativity and the supporting mathematical evaluation.
1865	James Clerk Maxwell (1831–1879)	Electromagnetic theory.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1874	Marie Alfred Cornu (1841–1902)	Described a graphical approach to the solution of diffraction problems: Cornu spiral.
1880	Leopold Kronecker (1823–1891)	Introduction of the “Kronecker Delta”, isolating the one single location in function space where a function can be considered rational. His studies primarily focussed on the ergodic theoretical aspects, describing dynamic systems.
1899	Jules Henri Poincaré (1854–1912) and Jacques Salomon Hadamard (1865–1963)	Geodesic flow; mathematical and analytical description.
1890	Jules Henri Poincaré (1854–1912)	Introduction of methods and means for deriving accurate topographical data. Some of the work of Poincaré revolved around defining the geometry of the universe. Poincaré also contributed to fluid dynamic modeling in addition to the description of celestial motion.
1895	Diederik Johannes Korteweg (1848–1941) and Gustav de Vries (1866–1934)	Diederik Korteweg and his student Gustav de Vries derived a nonlinear partial differential equation defining the propagation of waves in shallow water. The Korteweg–de Vries (KdV) equation describes the solitary wave described by John Scott Russell (1808–1882). The KdV equation has had an important implications for the development of the mathematical description of solutions.
1900	Samuel Giuseppe Vito Volterra (1860–1946)	Description and formulation of cylindrical waves. Volterra became involved in the biological cause and effect, respectively predator–prey aspects pioneering the field of mathematical biology.
1900	David Hilbert (1862–1943)	Hilbert space: vector space designed to accommodate an infinite number of dimensions, with respect to the three-dimensional Euclidean space. The Hilbert spatial interpretation forms an indispensable tools in solving for partial differential equations, as well as pertaining to quantum mechanics, and Fourier analysis. In Fourier analysis this applies to applications in signal processing and heat transfer. Hilbert space is an ergodic theory, which provides the mathematical foundations of certain thermodynamics topics.
1905	Albert Einstein (1879–1955)	Energy–mass equivalence hypothesis introduced. Einstein also published his theoretical interpretation of the movements of object, specifically approaching the speed of light in his special theory of relativity and general theory of relativity. In 1917 he published his predictions on stimulated emission and hence the preliminary description of the operations of a LASER. Additional mathematical work eludes to quantum theoretical approach.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1908	Hermann Minkowski (1864–1909)	Developed a geometrical interpretation of the special theory of relativity in which time and the three space coordinates all had the same validity in a four-dimensional continuum.
1910	Amalie Emma Noether (1882–1935)	Master of abstract algebra. Amalie Noether also introduced the concept of conservation laws based on the symmetry in nature and physics and engineering.
1910	Hermann Klaus Hugo (Peter) Weyl (1885–1955)	Weyl studied under David Hilbert (1862–1943) and was also close to Amalie Emma Noether (1882–1935). Hermann Weyl uncovered a gauge invariance and with his interpretation of Riemann surfaces his teachings form the basis of many aspects supporting the theoretical explanation in modern physics concepts. Weyl also contributed to the efforts of Erwin Schrödinger (1887–1961).
1910	Edmund Georg Hermann Landau (1877–1938)	Known for his work on prime number theory.
1916	Niels Henrik David Bohr (1885–1962)	Atomic structure and quantum theory.
1921	Alfred Landé (1888–1976)	Mathematician who introduced the Landau factor for an electron with both self-rotation spin and orbital angular momentum.
1924	Sir John Edward Lennard-Jones (1894–1954)	Definition of the attraction between two neutral molecules or atoms: Lennard-Jones potential.
1924–1945	Harry Nyquist (1889–1976) [Harry Theodor Nyqvist]	Combining mathematical approach to telecommunications and electronic engineering. His work started out to find the most elegant manner to suppress thermal noise. The Nyquist theorem, also referred to as the Nyquist–Shannon theorem, defines the sampling rate for period signals to ensure capturing all information contained in the transient signals.
1922	Erwin Rudolf Josef Alexander Schrödinger (1887–1961) and Hermann Klaus Hugo Weyl (1885–1955)	Introduction of the quantum mechanical principles, supporting the understanding of high energy physics phenomena such as the atomic structure.
1923	John von Neumann (1903–1957) [original name: Neumann Janos Lajos]	Introduced finite element methodology (also known as Monte Carlo simulation), integration of random number generation. He was also instrumental in the design of thermonuclear bombs as well as significantly advanced the field of hydrodynamics.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1924	Satyendra Nath Bose (1894–1974) [সত্যেন্দ্র নাথ বসু] and Albert Einstein (1879–1955)	Introduction of the Bose–Einstein statistics: one of two potential manners of energy occupation for a collection of noninteracting indistinguishable particles with respect to a set of available discrete energy states, this applies to thermodynamic equilibrium only. At extreme low temperatures these energy levels for bosons can result in a joining of states: condensation, the Bose–Einstein condensate.
1924	Louis-Victor-Pierre-Raymond, 7th duc de Broglie (1892–1987)	Introduction of the wave phenomenon with respect to all objects in motion. Matter wave, propagating with the de Broglie wavelength.
1925	Wolfgang Ernst Pauli (1900–1958)	Pauli exclusion principle for atomic energy levels.
1925	Werner Heisenberg (1901–1976)	Introduction of quantum mechanics, specifically in matrix formulation. Heisenberg also introduced the “uncertainty principle”; two parameters describing the same item or phenomenon cannot be known simultaneously with exact accuracy, such as momentum and position, but are inherently linked to each other with a product that yields the reduced Planck constant divided by two or greater.
1926	Eugene Paul Wigner (1902–1995)	Series publications on the application of group theory in quantum mechanics. Eugene Wigner shared the Nobel Prize in Physics jointly with Maria Goeppert-Mayer and Johannes Hans Daniel Jensen (1907–1973) in 1963.
1927	Wolfgang Ernst Pauli (1900–1958), Ralph Kronig (1904–1995), George Eugene Uhlenbeck (1900–1988), Samuel Abraham Goudsmit (1902–1978), and Paul Adrien Maurice Dirac (1902–1984)	Introduction of the electron spin concept and a broad range of relativistic quantum mechanical principles. This formed the foundation for the development of the NMR imaging system: nuclear magnetic resonance (MRI).
1935	Enrico Fermi (1901–1954)	Developed Fermi–Dirac statistics, although independent from Paul Dirac (1902–1984) but simultaneously. The Fermi–Dirac statistics applies to fermions; while the counterpart that it does not include are referred to as bosons. Fermi worked on X-ray crystallography, as well as energy levels in semiconductor structures. The Fermi level concept for electrons in atomic energy approximating absolute zero ties directly in with the Pauli exclusion principle. Fermi worked with and studied under Max Born (1882–1970), Werner Heisenberg (1901–1976), Pascual Jordan (1902–1980), Paul Ehrenfest (1880–1933), Hendrik Lorentz (1853–1928) Samuel Goudsmit (1902–1978), Jan Tinbergen (1903–1994), and Albert Einstein (1879–1955). Fermi concluded that beta decay from the nucleus formed another energetic particle and determined it to be real and named it a neutrino.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1935	Paul Adrien Maurice Dirac (1902–1984)	Developed Fermi–Dirac statistics, although independent from Enrico Fermi (1901–1954) but simultaneously.
1936	Inge Lehmann (1888–1993)	Description of the numerical assessment of data obtained during earthquakes (seismological data) and the image formation of the structure of the earth's structure, divided in shells with different material phase and composition. The image formation is based on what is referred to as S-waves and P-waves. Inge Lehmann discovered and described the shape, size, and composition (rudimentary) of the earth's inner core.
1945	Claude Elwood Shannon (1916–2001)	Sampling theory, minimum sampling rate for correct acquisition of periodic data. Sometimes introduced as the “father of information theory.” The work of Shannon paralleled that of Harry Nyquist (1889–1976).
1950	Maria Goeppert-Mayer (Göppert) (1906–1972)	Introduction and mathematical description of the nuclear shell model for atomic nuclei.
1972	Stephen Hawking (1942–), Jacob Bekenstein (1947–2015)	Thermodynamics of black holes.
1973	Sheldon Glashow (1932–), Abdus Salam (1926–1996), Steven Weinberg (1933), Carlo Rubbia (1934–) and Simon van der Meer (1925–2011)	Reference to a presumed, but so far unconfirmed unified field theory; based on the work of James Clerk Maxwell (1831–1879), Hans Christian Ørsted (1777–1851), and Michael Faraday (1791–1867). However, a better understanding of electro-weak interaction and electro-strong forces has certainly evolved from this research and mathematical analysis and modeling.
1995	Andrew Wiles (1953–)	One of the theorems introduced by Pierre de Fermat (1601–1665) in his “Arithmetica” is proved. The original theorem states the following: “no three positive integers a , b , and c can satisfy the equation $a^n + b^n = c^n$ for any integer value of n greater than two.”
1995	Edward Witten (1951–)	Introduction of “M-Theory”; also known as string theory, supported by Stephen Hawking (1942–). The M-theory attempts to reconcile quantum theory with gravity, but remains incomplete up to the date of this publication.

Dynamics

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 6000 BC	Egypt	First recorded drawings of rudimentary water crafts.
ca. 4000 BC	Eastern Europe	First recorded drawing of craft with rudimentary wheels.
ca. 3300 BC	Egypt	Drawings of sailboat.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
350 BC	Aristotle (384 BC–322 BC)	Founder of the Lyceum school of analytical thinking in Macedonia. Aristotle described the initial concepts of physics, motion, time as well as astronomy concepts. Aristotle supposed an external force (acting during flight) perpetuating the projectile motion of a ballistic object.
ca. 600 BC	Thales of Miletus (ca. 624 BC–ca. 546 BC; known as Thales: Θαλῆς)	Description of the “nature of objects.” Thales believed that objects are alive; part of the stream of thought by the “Hylozoists.”
ca. 250 BC	Archimedes (287 BC–212 BC)	Hand-operated cork-screw water pump. The philosophies of Archimedes shaped the development process of modern engineering.
40 BC	Marcus Vitruvius Pollio [Vitruvius] (ca. 80 BC–10 BC)	First recorded use and description of the mechanism of action of a steam-operated engine: Æolipile; described in <i>De Architectura</i> .
62	Hero of Alexandria [ῥων ὁ Ἀλεξανδρεὺς], (10–70)	Second recorded use of steam to provide power to a machine; Æolipile.
650		First recorded use of wind mills and wind energy in the Persian Empire.
1010	Eilmer of Malmesbury, 11th century Benedictine monk	First documented successful flight, performed with a wooden frame lined with parchment, traveling approximately 200 meter in free fall from a 18-meter elevation.
1206	Al-Jazari (1136–1206) [Turkey]; Badi’ al-Zaman Abū al-’Izz ibn Ismā’il ibn al-Razāz al-Jazarī (بْنُ الْعِزِّ أَبُو الزَّمَانِ بِسَدِيعِ الْجَزَارِيِّ الرَّزَازُ بْنُ إِسْمَاعِيلَ)	Publication of <i>Book of Knowledge of Ingenious Mechanical Devices</i> . Description of mechanical devices and mechanism of action.
1245	Thomas Aquinas (1225–1274)	Reformulation of the dynamic concepts of Aristotle (384 BC–322 BC).
1500	Leonardo da Vinci (1452–1519)	Formal description of physical phenomena based on the state-of-the-art mathematical definitions. Description of several machines, including “flying machines,” and a rudimentary theoretical discourse on the respective mechanism of action for several dynamic systems. Description of early friction concepts.
ca. 1600	Galileo Galilei (1564–1642)	Description of laws of motion (falling bodies; gravitational acceleration), projectile motion (ballistics), and inertia, before Sir Isaac Newton (1643–1727). Invented the pendulum clock and many more engineering feats.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1673	Christiaan Huygens (1629–1695)	Construction of a “combustion engine” power by gunpowder.
ca. 1687	Sir Isaac Newton (1643–1727)	Sir Isaac Newton introduced several laws of motion. The publication of the <i>Philosophiæ Naturalis Principia Mathematica</i> provides detailed definitions regarding ballistic motion, circular motion (centripetal force), laws of action–reaction, gravitational acceleration, inertia, and force with respect to acceleration. Introduction of the three laws of motion.
1699	Guillaume Amontons (1663–1705)	Formal introduction of the concept of friction, based on the rudimentary introduction by Leonardo da Vinci (1452–1519).
1698	Thomas Savery (1650–1715)	Construction of the basic steam engine.
1712	Thomas Newcomen (1664–1729)	Construction of an “atmospheric” steam engine.
1743	Jean-Baptiste le Rond d’Alembert (1717–1783)	Publication on the concepts of forces and accelerating systems: <i>Traite de Dynamique</i> .
1750	Leonard Euler (1707–1783)	Introduction of the coefficients representing kinetic and static friction.
1757–1769	James Watt (1736–1819)	Modern steam engine design and operation with theoretical description of operation.
1769	Nicolas-Joseph Cugnot (1725–1804)	First operational steam-powered automobile, the predecessor to the internal combustion automobile.
1781	Charles-Augustin de Coulomb (1736–1806)	Verification of the friction principles that were introduced by Guillaume Amontons (1663–1705).
1827	Benoît Fourneyron (1802–1867)	First water turbine.
1833	Arthur Jules Morin (1795–1880)	Differentiation between sliding and rolling friction.
1840	Claude-Louis Navier (1785–1836) and George Gabriel Stokes (1819–1903)	Fluid dynamics, friction concepts.
1866	Osborne Reynolds (1842–1912)	Friction description with respect to fluid dynamics concepts.
1879	Karl Friedrich Benz (1844–1929)	Invention of the internal combustion engine-driven automobile. Close collaboration with Gottlieb Wilhelm Daimler (1834–1900).
1880	Paul-Jacques Curie (1855–1941) and Pierre Curie (1859–1906)	Discovery of electric charges emerging on the surfaces of crystals which are subjected to shear or normal stress. This is referred to as the piezoelectric effect.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1880	Johannes Diederik van der Waals (1837–1923)	Description of the covalent bond. Van der Waals equation.
1888	John Boyd Dunlop (1840–1921)	Invention of the pneumatic tire.
1897	Joseph John Thomson (1856–1940)	Discovery of the electron; using William Crookes's vacuum tube.
1899	Jules Henri Poincaré (1854–1912) and Jacques Salomon Hadamard (1865–1963)	Geodesic flow; mathematical description and physical analysis. With further analysis by George David Birkhoff (1884–1944) in 1927.
1900	Rudolf Christian Karl Diesel (1858–1913)	Proof of principle that an engine (“diesel engine”) can operate on peanut oil. The mechanism was based on the efforts by Herbert Akroyd Stuart (1864–1927) in 1885.
1901	Ferdinand Porsche (1875–1951)	First hybrid automobile, internal combustion engine is used to rotate an electric generator, which in turn provides the power to operate a hub motor; an electric motor that is part of the axle of the automobile, attached to the wheel (ref. hubcap of the wheel).
1905	Orville Wright (1871–1948) and Wilbur Wright (1867–1912)	First sustained flight with a powered fixed-wing aircraft.
1909	Robert Andrews Millikan (1868–1953)	Measurement of the mass of the electron.
1915	Clinton Edgar Woods (1863–1930)	Hybrid automobile, powered by internal combustion engine as well as electric motor. Woods Motor Vehicle Company.
1916	Niels Henrik David Bohr (1885–1962)	Atomic structure and quantum theory.
1917	Ernest Rutherford, 1st Baron Rutherford of Nelson (1871–1937)	Discovery of the proton.
1924	Louis-Victor-Pierre-Raymond, 7th duc de Broglie (1892–1987)	Introduction of the wave phenomenon with respect to all object in motion. Matter wave, propagating with the de Broglie wavelength.
1927	Wolfgang Ernst Pauli (1900–1958) Paul Adrien Maurice Dirac (1902–1984)	Introduction of the electron spin concept, as a component of a broad range of quantum mechanical principles.
1924	Felix Heinrich Wankel (1902–1988)	Development and operation of the rotary engine (“Wankel motor”).
1931	Georges Jean Marie Darrieus (1888–1979)	Introduction of the wind turbine.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1937	Sir Frank Whittle (1907–1996)	Introduction of the jet engine.
1947	Chuck Yeager (1923–)	Breaking of the sound barrier during level flight.

ElectroTechnology_Electronic

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
c. 600 BC	Thales of Miletus (c. 624 BC–c. 546 BC; known as Thales: Θαλῆς)	Description of static electricity. Static electricity could specifically be induced by rubbing amber with animal fur, hence the association of the electric charge with the Greek word “amber” (referred to in Greek as electrum [ἤλεκτρον, translated as <i>ēlektron</i>]) meaning electron. Amber is solidified and hardened tree sap, resin.
500 BC	Leucippus (5th century BC)	Potential Greek philosopher who mentioned the fact that all matter is made up of indivisible, imperishable constituents, and referred to them as atoms. These atoms were not specific to the nature of the element in question under this hypothesis, but assumed to be all alike.
450 BC	Democritus (460 BC–370 BC)	Proposed the concept of the atomic nature of matter, presumably based on his work under Leucippus (5th century BC), but not confirmed as the original source.
1500	Leonardo da Vinci (1452–1519)	The preverbal “Renaissance man,” involved in all aspects of cultural evolution, science, engineering, politics, and art.
1503	Gregor Reisch (1467–1525)	Detailed outline of the state-of-the-art science and engineering knowledge to date, including human anatomical drawings in the publication <i>Margarita philosophica</i> . The total works of Gregor Reisch form a series of 12 books compiling an encyclopedia describing topics ranging from Latin grammar, to dialectics, rhetoric, arithmetic, music, geometry, astronomy, physics, natural history, physiology, psychology, and ethics
1512	Gregorius Reisch (1467–1525)	Introduction of the concept of the theodolite, used for topography and geographic location determination.
1543	Nicolaus Copernicus (1473–1543); Alias of Niclas Koppernigk	Introduction of the heliocentric model for the earth, sun, and planets close by. This follows the statement by the astronomer from Greece: Aristarchus of Samos (c. 310–c. 230 BC), made more than 1700 years prior. The scientific observations made by Copernicus were validated by Tycho Brahe (1546–1601) and Johannes Kepler (1571–1630).
1590	Francis Bacon, 1st Viscount of St. Alban (1561–1626)	Regulate the general scientific methodology.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 1600	Sir William Schwenck Gilbert (1544–1603)	Experimentalist. Description of the generation of “electricity” [electricus] when rubbing amber with fur. The term electron is derived from the Latin word used to describe the material amber: electrum, or the Greek word <i>ēlektron</i> : ἤλεκτρον.
ca. 1600	Galileo Galilei (1564–1642)	Major contributor to the scientific revolution and the (re) introduction of analytical thinking in science, engineering, and general thought processes. Galileo Galilei was remanded under house arrest by the Roman Inquisition for his views and teachings where he died after 9 years. This was the trailing end of the Renaissance period.
1614	René Descartes (1596–1650)	Introduction to vortex motion. Introduction of the concept of general corpuscular motion, extending from small (maybe referring to the undefined atom), to planetary orbits. Descartes also made an illustration of the earth’s magnetic field configuration in 1644, in his model the moon and celestial objects participated in the formation of the path of the magnetic field lines. Based on the limited experimental observations available in his time the premise was still not bad.
1632	Evangelista Torricelli (1608–1647)	Introduction of the barometer; essential in weather prediction; meteorology.
1650	Blaise Pascal (1623–1662)	Pascal’s law, pressure in a container applies an equal force on all surface of the enclosure.
1657	Otto von Guericke (1602–1686)	Electrostatic repulsion.
1660	Robert Boyle (1627–1691)	Gas laws, definition of the behavior of gases. Boyle mentioned the compression of gas as a potential “shock-absorber,” acting similar to a spring.
1673	Christiaan Huygens (1629–1695)	Construction of a “combustion engine” powered by gun powder. Huygens introduced several concept of mechanical engineering and described the mechanism of shock waves. Christiaan Huygens is most known for his lens manufacturing and optical design of telescopes. The mathematical efforts of Christiaan Huygens in probability theory were far advanced and he collaborated with the mathematician Pierre de Fermat (1601–1665) from France.
1679	Denis Papin (1647–c. 1712)	Pressure and thermodynamic and mechanical impacts.
1680	Robert Hooke (1635–1703)	Force applied by a compressed spring.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 1687	Sir Isaac Newton (1643–1727)	Sir Isaac Newton introduced several laws of motion. The publication of the <i>Philosophiæ Naturalis Principia Mathematica</i> provides detailed definitions regarding ballistic motion, circular motion (centripetal force), laws of action–reaction, gravitational acceleration, inertia, and force with respect to acceleration. Introduction of the three laws of motion.
1698	Francis Hauksbee the Elder (1660–1713)	Repeated the experiment of electrostatic repulsion performed by Otto von Guericke (1602–1686). Francis Hauksbee illustrated the preliminary concept of the gas discharge lamp. Hauksbee used the design of the electric charge generated from Otto von Guericke and applied vacuum, while adding charge to the ball in the center of the vacuum bulb, which resulted in the generation of a glow of light, resembling Saint Elmo's Fire. Gas discharge tubes over the next centuries evolved in neon lamp, mercury vapor lamps, and the fluorescent light.
1733	Charles François de Cisternay du Fay (1698–1739)	Discovery of a different electric charge, opposite to that of the recognized electron, such as the result of rubbing glass with silk, producing a positive charge, however not recognized as such by Charles du Fay just yet. Charles du Fay described the two opposing charge types as “vitreous” and “resinous,” respectively.
1745	Pieter van Musschenbroek (1692–1761) and Ewald Georg von Kleist (1700–1748)	Documented collection of electric charge (storage of static electricity) by means of the “Leyden Jar,” performed at the university in the city Leiden of the Netherlands.
1752	Benjamin Franklin (1706–1790)	Kite experiment and the documentation of “electric current.”
1781	Charles-Augustin de Coulomb (1736–1806)	Definition of the electric field related to electric charge. The electric charge itself was still an elusive concept in those days
1791	Luigi Aloisio Galvani (737–1798)	Discovery of bioelectricity, the preamble of the discovery of the actionpotential. Introduction of the galvanometer, the forerunner of the voltmeter.
1800	Count Alessandro Giuseppe Antonio Anastasio Volta (1745–1827)	Introduction of the battery; voltaic pile.
1821	Michael Faraday (1791–1867)	Discovery of electromagnetic rotation, leading to his law on electromagnetic induction in 1831. Meanwhile, in 1923 Michael Faraday experimentally verified the concept of refrigeration, introduced based on the work of John Dalton (1766–1844) in 1802 and William Cullen (1710–1790) in 1756.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1824	Nicolas Léonard Sadi Carnot (1796–1832)	Refrigerator for general public.
1825	William Sturgeon (1783–1878)	First documented design and application of the electromagnet. William Sturgeon also invented the first operational electric motor in 1832, operating on direct current (DC).
1827	George Simon Ohm (1789–1854)	Description of the linearly proportional relationship between voltage and current, introducing the resistance concept: Ohm's law.
1831	Michael Faraday (1791–1867) and Joseph Henry (1797–1878)	Law of electric induction, leading to the development of the electric generator, where a changing magnetic field induces an electromotive force (EMF), or known as electrical potential.
1833	Michael Faraday (1791–1867)	Recognition of the changes in resistance for materials when exposed to heat, providing the first introduction to the concept of semiconductor properties.
1839	Alexandre-Edmond Becquerel (1820–1891)	Description of the photovoltaic effect, which is different in principle from the photoelectric effect. When light is incident upon the surface of a material (metal or semiconductor), the electrons that reside in the valence band of certain elements of the semiconductor mixture or single metal absorb the electromagnetic energy and are raised to the conduction band (excited) and become free electrons, producing an electromotive force (EMF), yielding an electrical current. The photoelectric effect provided a step further in the recognition of the semiconductor concept, described in <i>Les Comptes Rendus de l'Academie des Sciences</i> . In contrast, the photoelectric effect describes the release of free electrons into free space, compared to conduction under photovoltaic effect. Alexandre-Edmond Becquerel was the father of Antoine Henri Becquerel (1852–1908), the prime discoverer of several fundamental radioactivity features. The photovoltaic effect led to the development of solar cells for the generation of electricity for personal consumption on a large scale.
1873	Josiah Willard Gibbs (1839–1903)	Chemical potential, a energy constituent within the Gibbs free energy. Thermodynamic concept describing the energy that can be released or absorbed during a chemical reaction.
1873	James Clerk Maxwell (1831–1879)	Theory of electromagnetic radiation: <i>A Treatise on Electricity and Magnetism</i> . James Maxwell made use of the prior work by Wilhelm Eduard Weber (1804–1891) and Johann Carl Friedrich Gauss {Gauß} (1777–1855)

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1873	Willoughby Smith (1828–1891)	First formal introduction to semiconductor materials. This was followed by the work of Karl Ferdinand Braun (1850–1918) in 1874 and Sir Franz Arthur Friedrich Schuster (1851–1934), also in 1874.
1874	Karl Ferdinand Braun (1850–1918)	Discovery that joining two materials with different electrical properties (metal vs. semiconductor) acts as a rectifier under certain conditions. This paved the way for the development of diodes and transistors when semiconductor materials became more manageable, and more manufacturable.
1878	Edwin Herbert Hall (1855–1938)	Discovery of the Hall effect: the deflection of electric charge flowing under the influence of an applied magnetic field. The Hall effect was instrumental in the evolution of the diode and in particular the transistor, using semiconductor junctions.
1878	Thomas Alva Edison (1847–1931)	This development of the incandescent light bulb. In 1883, Edison published the discovery of the emission of “electrons” (not known in that sense at that time yet) by a hot wire in an electrical circuit; “Edison effect.” The electron itself was recognized in 1897 by Joseph John Thomson (1856–1940).
1878	William Edward Sawyer (1850–1883)	Contributed to the development of the incandescent light bulb. There were several conflict on ownership to the right (patents) between William Sawyer and Thomas Edison (1847–1931).
1880	Johannes Diderik van der Waals (1837–1923)	Description of the covalent bond. Van der Waals equation.
1882	Thomas Alva Edison (1847–1931)	First commercial power plant serving Lower Manhattan, New York.
1883	Charles Fritts (1850–1903)	First solid-state photovoltaic cell created by coating the semiconductor material selenium with a thin layer of gold to form Schottky barrier junctions, based on the Fermi levels of the respective materials in contact, leading to the generation of electrical potential and electrical current under direct illumination by visible light. The concept device was only approximately 1% efficient, in comparison to current day better than 44%, and still increasing.
1885	George Westinghouse, Jr. (1846–1914)	Electric power distribution network development. George Westinghouse also invented what is known as air brakes (1869) drawing vacuum on a piston to reduce the revolutions of the crack axle, similar principles still apply to air brakes on large trucks.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1887	Heinrich Rudolf Hertz (1857–1894)	Radar development. Detection of electromagnetic radiation (radio waves). Heinrich Hertz also discovered that certain metal plates will release electrons (into free space) when exposed to light, specifically ultraviolet light: photoelectric effect. This concept was elaborated on by Albert Einstein (1879–1955) in 1905.
1893	Nikola Tesla (Serbian-Cyrillic: Никола Тесла; 1856–1943)	First alternating current (AC) electromotor. Nikola Tesla performed high voltage experiments, geared to induction, in Colorado and New York state. Nikola Tesla made significant contributions to the full complement of alternating current electrical device designs. Tesla also successfully experimented in remote control operations, as well as wireless communications. Nikola Tesla is most known for his extravagant experiments on wireless energy transmission, concerning significant voltage levels and current loads. The unit for magnetic flux was named after him in 1960 by General Conference on Weights and Measures, the Tesla. In 1888 Nikola Tesla demonstrated the functional polyphase brushless induction motor.
1893	Pieter Zeeman (1865–1943)	Description of the Zeeman effect: spectral line split under the influence of an applied static magnetic field (in contrast to the Stark effect, which was due to an applied electric field). Additional contributions were made by Hendrik Antoon Lorentz (1853–1928).
1897	Joseph John Thomson (1856–1940)	Discovery of the electron; using William Crookes's vacuum tube.
1897	Marchese Guglielmo Giovanni Maria Marconi, 1st Marquis of Marconi (1874–1937)	Introduction of wireless communications (radio telegraphy) and radio.
1898	Oliver Heaviside (1850–1925)	Description of the force on a point charge as the result of both an external magnetic and electric field; commonly known as the Lorentz force. James Clerk Maxwell (1831–1879) described a similar principle in a paper in 1855. The work of Hendrik Antoon Lorentz (1853–1928) refined the concept, hence the association of his name.
1898	Antoine Henri Becquerel (1852–1908)	Introduction of units for radioactivity radiation. Collaborator with Manya (Marie) Skłodowska Curie (1867–1934). Henri Becquerel, Marie Curie, and Pierre Curie shared the Nobel Prize in Physics for their radioactivity discoveries in 1903.
1900	Max Karl Ernst Ludwig Planck (1858–1947)	Inception of quantum mechanics.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1904	Sir John Ambrose Fleming (1849–1945)	Introduction of the vacuum tube as an electronic mechanism, either performing as a diode, transistor, or even working in the function of an operational amplifier. Student of James Clerk Maxwell (1831–1879).
1905	Albert Einstein (1879–1955)	Theoretical description of the photoelectro effect: emission of electrons from a metal exposed to light. the Einstein theory was confirmed by Robert Andrews Millikan (1868–1953) in 1914. The discovery of the ramifications of the photoelectric effect further fueled the development of the concept of quantum physics. Additional theoretical concepts introduced by Albert Einstein around that time are the theory of special relativity: Relationship between space and time—(1) the laws of physics are invariant in any and all inertial systems, based on a nonaccelerating frame of reference configuration; (2) the speed of light in vacuum is identical to all observers, regardless of the motion of the frame of reference for the light source. The theory is “special” since it applies to the special case of inertial reference frames.
1907	Captain Henry Joseph Round (1881–1966)	Formal introduction of the electroluminescence concept. This would eventually led to the production of light emitting diodes, after the work by Oleg Vladimirovich Losev (1903–1942) in 1927, but not produced until 1962. Henry Round worked as an assistant to Guglielmo Marconi, 1st Marquis of Marconi (1874–1937)
1913	Johannes Stark (1874–1957)	Stark effect: spectral line split under the influence of an applied static electric field (in contrast to the Zeeman effect, which was due to an applied magnetic field).
1913	Niels Henrik David Bohr (1885–1962)	Bohr atomic model, supporting the fundamental understanding of the p-type and n-type semiconductor principles and the general mode of conduction for valence electrons.
1915	Walter Hermann Schottky (1886–1976)	Development of the basic principles of electron layers resulting from his work on vacuum tubes, which principles also applies to the semiconductor barriers between n-doped and p-doped semiconductor media. The concepts that were introduced included the Schottky barrier, and the Schottky diode.
1916	Gilbert Newton Lewis (1875–1946)	Description of the shell filling for atomic electrons, and the related concept of valence electrons, next to the covalent chemical bond.
1926	Erwin Schrödinger (1887–1961)	Quantum mechanical wave equivalence, wave theory for atomic and nuclear energy configurations.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1925	Julius Edgar Lilienfeld (1882–1963)	First publication of the field-effect transistor concept (applicable to semiconductor media), but not practical for production. The concept was refined in 1938 by Rudolf Hilsch (1903–1972) and Robert Wichard Pohl (1884–1976), providing the solid-state (semiconductor; in contrast to the vacuum tube design in place at the time) amplifier. In 1931 Julius Lilienfeld also introduced the electrolytic capacitor.
1927	Werner Karl Heisenberg (1901–1976)	Uncertainty principle; impossibility to know both the location and the momentum (energy) of a system with absolute accuracy simultaneously. This also removed the causality aspect from events, and substitutes probabilistic distributions.
1927	Oleg Vladimirovich Losev [Russian: Олѣг Влади́мирович Ло́сев] (1903–1942)	Development of the light emitting diode (LED). However, the LED was not manufactured until 1962.
1928	Felix Bloch (1905–1983)	Description of the migration process of electrons in an atomic lattice structure. The electron transport formed what Felix Bloch referred to as a wave process, now referenced as Bloch waves. The wave process (i.e., wavelength) directly corresponds to the periodic nature of the lattice structure, in particular for a crystal.
1931	Georges Jean Marie Darrieus (1888–1979)	Introduction of the wind turbine, generating electricity based on induction under wind-powered rotation.
1948	Julian Schwinger (1916–1994), Richard Phillips Feynman (1918–1988), and Sin-Itiro Tomonaga (1906–1979)	Quantum electrodynamics and quantum field theory. Supporting the development of next-generation central processing units (CPUs) for computational applications (computer).
1950	John Alexander Hopps (1919–1998)	Introduction of the “portable” (~44 kg) cardiac pacemaker, based on the earlier work by Mark Lidwell (1878–1969) and Edgar Harold Booth (1893–1963) in 1926. This led, with the development of microprocessors, to the first implantable pacemaker in 1958 by William Chardack (1919–2011) and Wilson Greatbatch (1919–2011).
1957	Jack St. Clair Kilby (1923–2005)	Introduction of the integrated circuit (IC)—chip.
1969	Gordon Earle Moore (1929–), Marcian Edward “Ted” Hoff (1937–) and Federico Faggin (1941–)	Introduction of the microchip/microprocessor/CPU (central processing unit). Gordon Moore is one of the founders of the Intel Corporation. Gordon Moore also introduced a principle known as Moore’s law: the exponential increase of component density on a integrated circuit wafer with respect to years of development.

Energy

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
13.8 billion years BC	Georges Henri Joseph Édouard Lemaître (1894–1966) and Edwin Powell Hubble (1889–1953)	“The Big Bang”; in 1927 the expanding universe was recognized.
350 BC	Aristotle (384 BC–322 BC)	The word “energy” has the Greek origin “ <i>Enérgeia</i> ” [Greek: <i>ἐνέργεια</i>], which was documented by Aristotle, “ <i>Enérgeia</i> ” does not translate directly into English, the meaning resembles: “being at work.”
40 BC	Marcus Vitruvius Pollio [Vitruvius] (ca 80 BC–10 BC)	Architectural designs that harness the solar energy.
550	Ireland	Introduction of tidal mills. Work performed by machine based on the flow of water resulting from the changing tides in ocean and seawater level as well as resulting from the flow of rivers based on elevation (waterwheel).
650	Persia	First recorded use of wind mills and wind energy in the Persian Empire.
800	Persia, the Netherlands; detailed scientific documentation by Simon Stevin (1548–1620)	Wind energy used to pump water, windmill water pump: windpump. Other use of the windmill was in manufacturing, for example, papermaking, cloth fabrication, wheat processing, and later for the generation of electricity.
1500	Leonardo da Vinci (1452–1519)	Energy conservation principle illustrated (“described”) by several of the machines designed by Leonardo da Vinci.
ca. 1632	Galileo Galilei (1564–1642)	Account of friction in the energy exchange with respect to work. Additional work on energy conservation was described in the <i>Dialogue Concerning the Two Chief World Systems</i> , representing the Galilean invariance.
ca. 1687	Sir Isaac Newton (1643–1727)	Newton’s statement on “conservation of energy”: “Energy is not lost or destroyed, it is merely transferred from on party to the next.”
1698	Thomas Savery (1650–1715)	Construction of the basic steam engine.
1712	Thomas Newcomen (1664–1729) and John Calley (1663–1717)	Construction of an “atmospheric” steam engine.
1757–1769	James Watt (1736–1819)	Modern steam engine design and operation with theoretical description of operation.
1769	Nicolas-Joseph Cugnot (1725–1804)	First operational steam-powered automobile, the predecessor to the internal combustion automobile.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1776	Luigi Galvani (1737–1789)	Biomedical connection to electricity and development of a mechanism to measure electrical energy, respectively, electrochemical potential.
1781	Charles-Augustin de Coulomb (1736–1806)	Definition of the electric field related to electric charge. The electric charge was still an elusive concept in those days.
1800	Count Alessandro Giuseppe Antonio Anastasio Volta (1745–1827)	Introduction of the battery.
1820	Pierre Louis Dulong (1785–1838) and Alexis-Thérèse Petit (1791–1820)	Dulong and Petit law of specific heats.
1821	Thomas Johann Seebeck (1770–1831) and in 1834 Jean Charles Athanase Peltier (1785–1845) [greater detail]	Thermoelectric effect.
1827	Benoît Fourneyron (1802–1867)	First water turbine.
1831	Michael Faraday (1791–1867) and Joseph Henry (1797–1878)	Law of induction, leading to the development of the electric generator.
1845	James Prescott Joule (1818– 1889)	Energy definition; mechanical equivalence of heat.
1839	Sir William Robert Grove (1811–1896)	Introduction of the first hydrogen–oxygen fuel cell.
1861	Augustin Mouchot (1825–1911)	Presentation of the use of solar energy as a source for personal energy consumption.
1865	August Joseph Ignaz Toepler (1836–1912)	Electrostatic charge generation.
1873	Josiah Willard Gibbs (1839–1903)	Chemical potential, a energy constituent within the Gibbs free energy. Thermodynamic concept describing the energy that can be released or absorbed during a chemical reaction.
1876	Alexander Graham Bell (1847–1922)	Introduction of the telephone. Other efforts involved hydrofoils and aeronautics.
1877	Thomas Edison (1847–1931)	Introduction of the phonograph and telegraph machine and the electric light bulb.
1880	Johannes Diderik van der Waals (1837–1923)	Description of chemical bonding energy. Van der Waals equation.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1880	James Wimshurst (1832–1903)	Electrostatic charge generation.
1888	Inspired by Michael Faraday (1791–1867)	First electric power generator by means of induction based on revolutions provided by a bush postmill, wind energy.
1892	Sir John Ambrose Fleming (1849–1945)	Electrical transformer theory and communications. Introduction of the thermionic valve, electronic device.
1893	Nikola Tesla (1856–1943)	Design of modern alternating current technology. Worked for Thomas Edison (1847–1931) on telephony. On his own, he developed the induction motor design. Tesla also worked on X-ray imaging and radio transmission.
1897	Joseph John Thomson (1856–1940)	Discovery of the electron; using William Crookes's vacuum tube.
1900	Max Karl Ernst Ludwig Planck (1858–1947) and James Clerk Maxwell (1831–1879)	Formal description of the photon and the energy associated with the electromagnetic wave.
1904	Piero Ginori Conti, Prince of Trevignano, (1865–1939)	Geothermal electric generator.
1914	Niels Henrik David Bohr (1885–1962)	Description of the atomic energy layer model; hydrogen (Bohr atomic model).
1918	Paul Scherrer (1890–1969)	X-ray diffraction, crystal structure. nuclear energy development. Established the CERN institute in Switzerland as one of the founders. Directed the construction of the first cyclotron in 1940.
1923	Arthur Holly Compton (1892–1962)	Description of the deflection of photons by a nucleus: Compton effect.
1927	Werner Karl Heisenberg (1901–1976)	Quantum uncertainty principle.
1927	Paul Adrien Maurice Dirac (1902–1984)	Description of antimatter.
1929	Robert Jemison van de Graaff (1902–1967)	Electrostatic charge generation.
1931	Carl David Anderson (1905–1991)	Discovery of the positron, anti-particle for the electron. The “positron” was predicted by Paul Adrien Maurice Dirac (1902–1984) in 1929.
1931	Georges Jean Marie Darrieus (1888–1979)	Introduction of the wind turbine.
1932	Sir James Chadwick (1891–1974)	Discovery of the neutron.
1934	Hideki Yukawa [湯川秀樹], (1907–1981)	Introduction of mesons and the concept of antimatter.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1937	Carl David Anderson (1905–1991), Seth Henry Neddermeyer (1907–1988), Jabez Curry Street (1906–1989) and Edward C. Stevenson (1937–)	Confirmation of the existence of the meson, and muon.
1940+	Julius Robert Oppenheimer (1904–1967)	Manhattan project: fission reaction. Prominent members: Arthur Compton (1892–1962); Enrico Fermi (1901–1954); Eugene Wigner (1902–1995), and dozens more.
1947	William Webster Hansen (1909–1949)	Linear accelerator installation at Stanford University, California.
1950	Maria Goeppert-Mayer (Göppert) (1906–1972)	Introduction of the nuclear shell model for atomic nuclei.
1955	Obninsk Nuclear Power Station, Russia	First nuclear power station for energy generation.
1958	Stanley Mandelstam (1928–2016)	Introduction of Mandelstam variables associated with the concept of “crossing symmetry,” defining numerical quantities which encode the energy, momentum, and scattering angles of particles in a deflection process described in a Lorentz invariant fashion.
1958	Lev Davidovich Landau [Russian: Лёв Давидович Ландау] (1908–1968), Arkady Beynusovich Migdal [Russian: Аркадий Бейнусович Бенедиктович Мигдаль] (1911–1991)	Theory of interacting electrons, specifically with respect to solids; condensed matter physics.
1960	George Irving Bell (1926–2000)	Fundamental contributor to the evolution of the nuclear energy program.
1961	Murray Gell-Mann (1929–)	Description of elementary particles, eight-fold way of defining “strangeness” for the quark.
1964	Charles Hard Townes (1915–2015), Nikolay Gennadiyevich Basov [Николай Геннадиевич Басов] (1922–2001) and Aleksandr Mikhailovich Prokhorov [Александр Михайлович Прохоров] (1916–2002)	Quantum electronics.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1972	Stephen Hawking (1942–), Jacob Bekenstein (1947–2015)	Thermodynamics of black holes.
1978		Discovery of the “gluon” with the assistance of the Pluto, the first electromagnetic superconductive solenoid located in Hamburg, Germany.
1983	Collider detector at Fermilab	World’s first and at the time highest-energy particle accelerator, colliding antiprotons and protons propelled to center-of-mass energy reaching 2 TeV.
1995	Wolfgang Ketterle (1957–), Eric Allin Cornell (1961–), and Carl Edwin Wieman (1951–)	Experimental verification of Bose–Einstein condensation.
2012	François Baron Englert (1932–) and Peter Ware Higgs (1929–)	Higgs boson (126 GeV) discovery in the Large Hadron Collider at CERN, Geneva, Switzerland. The Large Hadron Collider construction started in 1998 and produces particle acceleration with respective energy levels for protons at up to 4 teraelectronvolts (0.64 microjoules), or lead nuclei: 2.76 TeV per nucleon or 574 TeV per nucleus. The proton energy level was increased to 6.5 TeV in 2015.

Engineering

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1.8 million years BC		Use of stone tools, axe, scraper, and hammer.
200000 BC		<i>Homo sapiens</i> .
25000 BC		Ceramics; baked clay.
9000 BC		Bow and arrow.
6000 BC–2000 BC	Stone Age	Mechanical labor and tool fabrication.
c. 6000 BC	Egypt	First recorded drawings of rudimentary water crafts.
c. 4000 BC	Eastern Europe, Arabic nations, Mesopotamia (specifically: Sumeria/ Sumer)	First recorded drawing of craft with rudimentary wheels. Most prominent: use of pieces/slice of tree trunk as wheel, attached to an axle (Ljubljana, Slovenia).
4000 BC	Mesopotamia and Egypt	Documented recording of the construction of shelter, abandoning the nomadic structure.
4000 BC		First documented use of lime-based mortar. Prior to this most building assembly relied on clay or mud as the cohesive element to connect stone blocks together.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
c. 3500 BC		First documented installation of sewer systems, primarily run-off.
c. 3300 BC	Egypt	Drawings of sail boats.
3300 BC–1000 BC	Bronze Age	Smelting and forging of soft metals using low heat: copper, tin, and gold. This age also introduces the written documentation.
2700 BC–2500 BC	Egypt	Construction of pyramids, requiring advanced mechanical engineering efforts and architectural design (civil engineering).
1600 BC	Babylonian empire	Use of water clocks for time keeping.
c. 1000 BC	Qanat aqueduct; Persia	Water supply over a length greater than 71 km, and potential relation with sewer as a secondary use for liquid transport as part of the civil engineering efforts.
1000 BC–700 AD	Iron Age	Higher heat requirements and more detailed tool manufacturing, introducing scientific and engineering challenges. Historical tracking of processes and developments and philosophies. Introduction of complicated mechanisms and requiring detailed analytical thinking.
c. 600 BC	Thales of Miletus (ca. 624 BC–ca. 546 BC; known as Thales: Θαλῆς)	Introduction of metrology, measurements of the height of pyramids with proposed standards. Introduced the concept of logic proof.
520 BC	Pythagoras (571 BC–495 BC)	Pythagorean theorem for a triangle.
430 BC	Socrates (469 BC–399 BC)	Scholar and educator, introducing analytical thinking.
c. 360 BC	Plato (427 BC–347 BC)	Student of Socrates (469 BC–399 BC). Founder of the principles for modern philosophy and science. The Plato school of teaching included, but not limited to astronomy, biology, mathematics, philosophy, and political theory.
300 BC	Roman empire	Waterwheel used for drainage next to perform work.
350 BC	Aristotle (384 BC–322 BC)	Introduction of modern physical science concepts (natural philosophy) and logic (including deductive reasoning). Aristotle's attention in teaching ranged from anatomy, to astronomy (promoting the wrong concept of a geocentric system for earth and the sun), embryology, geography, geology, meteorology, including physics as well as zoology.
c. 310 BC	Euclid (c. 350 BC–c. 275 BC)	Euclidean geometry; still valid for classical mechanics.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
c. 300 BC	Zhou Bi Suan Jing (周髀算經) (Zhou Dynasty (1046 BC–256 BC))	Documented proof of the Pythagorean theorem, shortly after the “western” proof by Pythagoras (571 BC–495 BC)
c. 250 BC	Archimedes (287 BC–212 BC)	Revealed the properties that define buoyancy. Developed calculus and algebra and created a system for “abbreviating” large numbers by means of what we now consider exponential expressions. Archimedes also described the mechanics of a level, defining torque. Still primarily statics.
c. 280 BC–247 BC	Alexandria, Egypt	Lighthouse of Alexandria. The city of Alexandria was erected by Alexander the Great of Macedon [Greek: Ἀλέξανδρος ὁ Μέγας] (356 BC–323 BC) in 332 BC. The lighthouse was one of the tallest man-made architectural structures for many centuries and was partially destroyed as a result of a series of earthquakes over the period 956–1323.
c. 220 BC	China	Civil engineering effort of the architectural and mechanical design and construction of the Great Wall, Ming Dynasty. As mortar the engineers used sticky rice
142 BC	Rome, Italy	Oldest known arch bridge, made from stone.
40 BC	Marcus Vitruvius Pollio [Vitruvius] (ca 80 BC–10 BC)	Roman engineering architect and civil engineer. Vitruvius served under Gaius Julius Caesar (100 BC–44 BC). In the army position, he was also charged with the care of the infirmed, where he used early biomedical engineering approaches for novel diagnosis and treatment. Vitruvius provided a detailed description of the preparation and use of lime-based gypsum mortar for construction use. The Romans added volcanic ash to make the concrete mixture resistant to water, and used it in the construction of aqueducts; lime itself will not harden or will decay when continuously exposed to water. Description of the use of a waterwheel to measure the distance traveled by a ship (odometer).
10 BC	Strabo (64 BC–24 AD)	Description of the use of a waterwheel-powered mill; Turkey/Egypt/Mesopotamian empire.
62	Hero of Alexandria [ῥωνό Ἀλεξανδρεὺς], (10–70)	Mathematician, physicist, and mechanical engineer who also taught pneumatics. A set of two books: <i>The Pneumatica</i> describes mechanical devices worked by air, steam, or water pressure. Also known as Heron of Alexandria. He invented a steam-powered engine called the “Æolipile.”
105	Apollodorus of Damascus (2nd century)	Architect and construction engineer for the longest known ancient technology arch bridge over the river Danube: Trajan Bridge. The bridge was created to facilitate the transport of troops across Europe.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
120	Claudius Ptolemy {Ptolemaeus} [Πτολεμαῖος] (90–168)	Geographic recordings of a significant part of the Islamic and Western world (i.e., Roman and Persian Empire), living in Egypt, as a Roman with Greek education. His cartography extended all the way out, including parts of China (discovered in 15th century). He specifically developed arithmetical techniques for calculating astronomical phenomena, under the teachings of Babylonian astronomers. Also known as: بطليموس (Batlamyus; Arabic).
132	Zhang Heng (78–139)	First known construction and use of a seismograph, Han Dynasty.
400	Roman empire	Description of the use of a waterwheel for propulsion of a boat by means of an ox: paddle-wheel (publication <i>De Rebus Bellicis</i>).
644		Wind-powered devices developed by the Persians.
900–1200	Mexico, central America	Construction of temples which apparently have a close correlation to astronomical observations. Civil engineering.
1176	France	Mechanical clock tower: “horologe”; presumably powered by running water.
1430	Philip the Good, Duke of Burgundy (1396–1467)	Spring-driven clock.
1450	Machu Picchu, Peru	Construction of an Incan citadel in the Andes mountains. No mortar (no cement) was used in the assembly process.
1500	Leonardo da Vinci (1452–1519)	The preverbal “Renaissance man,” involved in all aspects of cultural evolution, science, engineering, politics, and art. Da Vinci designed a water-powered gyroscopic compass.
1510	Peter Henlein (1485–1542)	Spring-driven time-keeping device: clock; “Nuremberg-egg” pocket watch.
1590	Francis Bacon, 1st Viscount of St. Alban (1561–1626)	Regulate the general scientific methodology.
c. 1600	Galileo Galilei (1564–1642)	Major contributor to the scientific revolution and the (re) introduction of analytical thinking in science, engineering, and general thought processes. Galileo Galilei recognized that motion would be uninterrupted if there were no constraints; that is, no friction.
1614	René Descartes (1596–1650)	Introduction to vortex motion. Introduction of the concept of general corpuscular motion, extending from small (maybe referring to the undefined atom), to planetary orbits.
1632	Evangelista Torricelli (1608–1647)	Introduction of the barometer; essential in weather prediction; meteorology.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1650	Blaise Pascal (1623–1662)	Pascal's law, pressure in a container applies an equal force on all surface of the enclosure.
1660	Robert Boyle (1627–1691)	Gas laws, definition of the behavior of gases. Boyle mentioned the compression of gas as a potential “shock-absorber,” acting similar to a spring.
1673	Christiaan Huygens (1629–1695)	Construction of a “combustion engine” powered by gun powder. Huygens introduced several concept of mechanical engineering and described the mechanism of shock waves. Christiaan Huygens is most known for his lens manufacturing and optical design of telescopes. The mathematical efforts of Christiaan Huygens in probability theory were far advanced and he collaborated with the mathematician Pierre de Fermat (1601–1665) from France.
1679	Denis Papin (1647–c. 1712)	Pressure and thermodynamic and mechanical impacts.
1680	Robert Hooke (1635–1703)	Force applied by a compressed spring, linearly proportional to the compression length: spring constant.
c. 1687	Sir Isaac Newton (1643–1727)	Sir Isaac Newton introduced three laws of motion dynamics: (1) an object remains at rest, or move in steady-state velocity, unless an externally applied force persuades it to change the status quo; (2) the sum of the forces acting on a body will change the motion (i.e., acceleration) of that body in a linear proportion and in the direction of the resultant of these forces, (3) for every action there is an equal but opposite reaction. The publication of the <i>Philosophiæ Naturalis Principia Mathematica</i> provides detailed definitions regarding ballistic motion, circular motion (centripetal force), laws of action–reaction, gravitational acceleration, inertia, and force with respect to acceleration. Introduction of the three laws of motion.
1698	Thomas Savery (1650–1715)	Construction of the basic steam engine; using information obtained by Denis Papin (1647–c. 1712).
1705	Edmond Halley (1656–1742)	Discovery of, and mathematical description of the trajectory for “Halley's comet.”
1712	Thomas Newcomen (1664–1729)	Construction of a “atmospheric” steam engine.
1714	Brook Taylor (1685–1731)	Fundamental frequency of vibration; string. Additional work on pure mathematics: Taylor series.
1727	Leonard Euler (1707–1783)	Introduction of the concept of the elastic modulus, experimentally verified by Giordano Riccati (1709–1790) in 1782 and mathematically introduced by Thomas Young (1773–1829) in 1807, now known as Young's modulus.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1732	Anders Celsius (1701–1744)	Thermometer scale calibration based on pure water phases.
1733	Daniel Bernoulli (1700–1782)	Acoustics, mechanical vibrations, and fluid-dynamic principles introduced. Definition of the fundamental frequency and higher harmonics, with supporting elaborate mathematical analysis (solutions to differential equations).
1735	Daniel Gabriel Fahrenheit (1686–1736)	Temperature scale in Fahrenheit based on body temperature and saltwater phases.
1743	Jean-Baptiste le Rond d'Alembert (1717–1783)	Publication on the concepts of forces and accelerating systems: <i>Traite de Dynamique</i> .
1752	Benjamin Franklin (1706–1790)	Kite experiment and the documentation of “electric current.”
1756	John Smeaton (1724–1792)	Introduction of pozzolans (pozzolanic earth) mixed in with mortar to provide a water-resistant cement mortar.
1757–1769	James Watt (1736–1819)	Modern steam engine design and operation with theoretical description of operation.
1762	Joseph Black (1728–1799)	Realization of the concept of latent heat.
1760–1820		Industrial Revolution.
1769	Nicolas-Joseph Cugnot (1725–1804)	First operational steam-powered automobile, the predecessor to the internal combustion automobile.
1781	Charles-Augustin de Coulomb (1736–1806)	Definition of the electric field related to electric charge. The electric charge itself was still an elusive concept in those days. Introduction to the scientific aspects of electrical engineering.
1783	Antoine Laurent de Lavoisier (1743–1794)	Discovery of oxygen and the chemical impact, oxidation. Scientific approach to the chemical engineering aspects of phenomena, both natural and artificial.
1783	Joseph-Michel Montgolfier (1740–1810) and Jacques-Étienne Montgolfier (1745–1799)	Hot-air balloon; buoyancy.
1785	Jacques Alexandre César Charles (1746–1823)	Charles's law, expansion of gases.
1800	Count Alessandro Giuseppe Antonio Anastasio Volta (1745–1827)	Introduction of the battery. The introduction of the electrical engineering aspect of technology.
1802	Joseph Louis Gay-Lussac (1778–1850)	Ideal gas law; building on the work by Robert Boyle (1627–1691), more than a century earlier.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1807	Thomas Young (1773–1829)	Formal introduction of the Young's modulus for elastic deformation, tying strain to stress, based on the work by Leonard Euler (1707–1783).
1821	Michael Faraday (1791–1867)	Discovery of electromagnetic rotation, leading to his law on electromagnetic induction in 1831. Meanwhile, in 1923 Michael Faraday experimentally verified the concept of refrigeration, introduced based on the work of John Dalton (1766–1844) in 1802 and William Cullen (1710–1790) in 1756.
1824	Joseph Aspdin (1778–1855)	Introduction of portland cement; mixture of limestone, clay, and a blend of minerals in carefully controlled proportions. The constituents of the Portland cement were calcined (thermal treatment process used for decomposition or purification) and ground into a fine aggregate of particles. portland cement versus primarily produced and distributed from within Europe.
1824	Nicolas Léonard Sadi Carnot (1796–1832)	Refrigerator for general public.
1827	Benoît Fourneyron (1802–1867)	First water turbine.
1831	Michael Faraday (1791–1867) and Joseph Henry (1797–1878)	Law of induction, leading to the development of the electric generator.
1840	Jean Léonard Marie Poiseuille (1799–1869) and Gotthilf Heinrich Ludwig Hagen (1797–1884)	Pressure drop for incompressible fluids with respect to laminar flow.
1848	William Thomson, 1st Baron Kelvin (i.e., Lord Kelvin) (1824–1907)	Absolute temperature scale: Kelvin.
1851	Jean Bernard Léon Foucault (1819–1868)	Foucault pendulum, illustrating the impact of the earth's rotation on motion.
1852	James Prescott Joule (1818–1889) and William Thomson, 1st Baron Kelvin {Lord Kelvin} (1824–1907)	Joule-Thomson effect: rapidly expanding gas leads to a reduction in the temperature of the gas, even offering the potential for a phase change to solid, or liquid. Sometimes also found as the Joule-Kelvin effect.
1854	Robert Wilhelm Eberhard Bunsen (1811–1899)	Bunsen burner.
1859	James Clerk Maxwell (1831–1879)	Description of the distribution law of molecular velocities.
1861	Augustin Mouchot (1825–1911)	Presentation of the use of solar energy as a source for personal energy consumption.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1866	Ludwig Eduard Boltzmann (1844–1906) and Josiah Willard Gibbs (1839–1903)	Statistical mechanics, correlating energy, and heat, to the movement (velocity).
1873	Josiah Willard Gibbs (1839–1903)	Chemical potential: a energy constituent within the Gibbs free energy. Thermodynamic concept describing the energy that can be released or absorbed during a chemical reaction.
1873	James Clerk Maxwell (1831–1879)	Theory of electromagnetic radiation: <i>Treatise on Electricity and Magnetism</i> . James Maxwell made use of the prior work by Wilhelm Eduard Weber (1804–1891) and Johann Carl Friedrich Gauss {Gauß} (1777–1855).
1875	Siegfried Samuel Marcus (1831–1898)	Siegfried Marcus automobile, powered by an internal combustion engine; Vienna, Austria. Predecessor to the “modern” automobile. In 1883 Siegfried Marcus received a patent on a ignition magnet (ignition magneto), now know as a distributor, providing ignition electrical discharges to then respective cylinders in the correct order and on-time at the correct cylinder position, just a few degrees before the piston connecting-rod stretches to the top of the cylinder.
1880	Johannes Diderik van der Waals (1837–1923)	Description of the covalent bond. Van der Waals equation.
1883	John Joseph Montgomery (1858–1911)	Montgomery glider; first piloted flight with an aircraft “heavier than air” (vs. the hot-air balloon) transporting human passengers. Montgomery fell victim to his own ingenuity and died in a crash of one of his glider designs.
1887	Heinrich Rudolf Hertz (1857–1894)	Radar development. Detection of electromagnetic radiation (radio waves). Heinrich Hertz also discovered that certain metal plates will generate electricity when exposed to light: photoelectric effect.
1891		Manitou Springs, Colorado: Cog railway leading up to the top of Pikes Peak of the Rocky Mountains, mountain ridge.
1894	Max Karl Ernst Ludwig Planck, (1858–1947)	Black-body radiation.
1895	Folsom, California	First operational hydroelectric power plant.
1897	Guglielmo Marconi, 1st Marquis of Marconi (1874–1937)	Introduction of wireless communications and radio.
1900	Anne Rainsford French Bush (1878–1962)	First licensed female steam engineer in the United States of America.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1900	Ferdinand Adolf Heinrich August Graf von Zeppelin (1838–1917)	Successful dirigible, gas-filled air floatation device with propulsion.
1925	Karl von Terzaghi (1883–1963)	Foundation of geotechnical engineering, considered a subsection of civil engineering, linking structural design to the soil foundation mechanical conditions. Publication: <i>Erdbaumechanik</i> . One specific example of the influence of Karl von Terzaghi is the maximum slope (abutment; 90 degrees being vertical) for a dam that will hold under its own weight, such as found in ridges on which railways are raised above the topography of the terrain, or the design and construction of levees. For sand, the slope is roughly 45 degrees, whereas for bricks or clay the slope can be stable up to 60°.
1926	Mark Cowley Lidwell (1878–1969) and Edgar Harold Booth (1893–1963)	Rudimentary, but effective, external cardiac pacemaker design.
1930	Richard Buckminster Fuller (1895–1983)	Mechanical engineering and engineering architecture, as well as chemistry; Bucky-ball, multipoint connections in both chemical structures and mechanical structures.
1931	Georges Jean Marie Darrieus (1888–1979)	Introduction of the wind turbine.
1937–1959	Chester Floyd Carlson (1906–1968)	Photocopy machine, patented in 1942. The first photocopier was offered for sale by the Haloid company in 1959, later renamed Xerox.
1950	John Alexander Hopps, (1919–1998)	Introduction of the “portable” (45 kg) cardiac pacemaker, based on the earlier work by Mark Lidwell (1878–1969) and Edgar Harold Booth (1893–1963) in 1926. This led, with the development of microprocessors, to the first implantable pacemaker in by William Chardack (1919–2011) and Wilson Greatbatch (1919–2011).
1956	Paul Winchell {Wilchinsky} (1922–2005)	Artificial heart (Jarvik 7).
1969	NASA	First lunar landing; Apollo 11: Neil Armstrong (1930–2012), Michael Collins (1930–) [commander of lunar orbiter module], and Buzz Aldrin {Edwin Eugene Aldrin Jr} (1930–).
1979	K.V. Hall, R.L. Kaster, A. Wøien	Application of an in vivo artificial bileaflet replacement heart valve.

(Continued)

Fluid Dynamics

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 3300 BC	Egypt	Drawings of sailboat.
ca. 2000 BC	Egypt; India	Irrigation systems.
350 BC	Aristotle (384 BC–322 BC)	Founder of the Lyceum school of analytical thinking in Macedonia. Aristotle described the initial concepts of physics, motion, time as well as astronomy concepts. Aristotle supposed an external force (acting during flight) perpetuating the projectile motion of a ballistic object.
144 BC	Italy	Construction of aqueducts.
1010	Eilmer of Malmesbury, 11th century Benedictine monk	First documented successful flight, performed with a wooden frame lined with parchment, traveling approximately 200 meter in free fall from a 18 meter elevation.
1206	Al-Jazari (1136–1206) [Turkey]; Badi' al-Zaman Abū al-'Izz ibn Ismā'il ibn al-Razāz al-Jazarī (بْنُ الْعِزِّ أَبُو الزَّمَانِ بَدِيعُ)	Publication of <i>Book of Knowledge of Ingenious Mechanical Devices</i> . Description of mechanical devices and mechanism of action.
1245	Thomas Aquinas (1225–1274)	Reformulation of the dynamic concepts of Aristotle (384 BC–322 BC).
1500	Leonardo da Vinci (1452–1519)	Description of early friction concepts, and derivation of the conservation of mass equation for one-dimensional flow. Documented descriptions of wave phenomena, fluid jets, hydraulic pumps, eddy current formation, and low-drag flow as well as high-drag (turbulent flow around an object being pulled through a fluid) flow.
1586	Galileo Galilei (1564–1642)	Investigation on the aspect of drag (friction) on falling objects. The Galilei number is the ratio of the gravitational forces over the viscous forces, yielding a dimensionless number; however, the number was not introduced by Galileo Galilei.
ca. 1660	Edme Mariotte (1620–1684)	First wind tunnel construction to test some of the concepts introduced by Leonardo da Vinci (1452–1519), and his own observations and curiosity.
ca. 1687	Sir Isaac Newton (1643–1727)	Sir Isaac Newton introduced the three laws of motion. His additional contributions in fluid dynamics describe the law of viscosity for linear fluids. Linear fluids (idealized fluid) are referred to as Newtonian fluids.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1699	Guillaume Amontons (1663–1705)	Formal introduction of the concept of friction, based on the rudimentary introduction by Leonardo da Vinci (1452–1519).
1732	Henry de Pitot (1695–1771)	Investigation of the velocity of flow as a function of depth, disproving the leading theory that flow velocity increases with depth. Original design of the “Pitot tube” used to measure the flow velocity.
1738	Daniel Bernoulli (1700–1782)	Demonstration of the Bernoulli’s principle: relationship between flow velocity and pressure, for inviscid flow. The Bernoulli principle defines the behavior of flight with respect to lift on the airplane wing, as well as the mixing of fluids (combustible and air for a carburetor. Published in <i>Hydrodynamica</i> .
1743	Jean-Baptiste le Rond d’Alembert (1717–1783)	Publication on the concepts of forces and accelerating systems: <i>Traite de Dynamique</i> . Mathematical description of frictionless flow.
1750	Leonard Euler (1707–1783)	Introduction of the coefficients representing kinetic and static friction; creation of what we consider the Bernoulli equation, differential flow formulation as well as the integral form.
1765	Antoine de Chézy (1718–1798)	Description of steady-state turbulent flow in an open channel, linking the average velocity to the radius of the channel and the depth of the flow.
1781	Charles-Augustin de Coulomb (1736–1806)	Verification of the friction principles that were introduced by Guillaume Amontons (1663–1705).
1797	Giovanni Battista Venturi (1746–1822)	A tube with two tapered ends joining at the narrow ends provides a drop in pressure. This “ventury” can provide suction when a hole is placed in this narrow passage.
1811	Augustin Louis de Cauchy (1789–1857)	Mathematical description of wave phenomena in elastic media and elastic membranes. Cauchy also introduced the concept and definition for stress, which are complementary to those of Siméon Denis Poisson (1781–1840).
1820	Gotthilf Heinrich Ludwig Hagen (1797–1884)	Theoretical design for hydraulic engineering projects.
1838	Jean-Louis Léonard Marie Poiseuille (1799–1869)	Introduction of the Hagen–Poiseuille law describing nonturbulent flow through a compliant system (e.g., blood vessels, primarily applicable to smaller diameter vessels), crediting the influence of Gotthilf Heinrich Ludwig Hagen (1797–1884). The flow applies to steady-state conditions for a Newtonian fluid that is incompressible.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1839–1868	Heinrich Gustav Magnus (1802–1870)	Description of the process of absorption of gases in blood (respiration); vapor pressure for evaporated liquids. A projectile spinning object will veer away from the original trajectory: Magnus effect. This applies, for instance, to rotating propellers and pitched baseballs.
1840	Claude-Louis Navier (1785–1836) and George Gabriel Stokes (1819–1903)	Fluid dynamics based on Newton's second law concepts incorporating friction concepts and pressure gradient: Navier–Stokes equations.
1845	Henry Philibert Gaspard Darcy (1803–1858)	Redisign of the Pitot tube, used to measure the local flow velocity. Still in use to measure the speed of flight for airplanes.
1850	Julius Ludwig Weisbach (1806–1871)	Refined the work of Henry Philibert Gaspard Darcy (1803–1858) and wrote a series of physics textbooks. Weisbach studied under Johann Carl Friedrich Gauss (1777–1855).
1861	William Froude (1810–1879)	Applications to ship design, reducing the roll of a ship by means of a keel. The hydrodynamic behavior of the hull of a ship could be gauged based on the Froude number, derived from a set of experimental obtained data points.
1875	Lord Rayleigh (1842–1919) [John Strutt]	Dimensional analysis technique to provide a theoretical approach with regard to diabatic incompressible flow in a system with a constant cross-sectional area, neglecting the heat exchange aspects.
1877	Ernst Waldfried Josef Wenzel Mach (1838–1916)	Study and description of shock waves, introduced the Mach number for travel velocity with respect to the speed of sound. Additional work of Ernst Mach was in interferometry, Doppler effect aspects and acoustics.
1878	Vincen Strouhal (1850–1922)	Introduction of a dimensionless parameter that describes the tail or wing kinematics of swimming and flying animals in addition to flying object with fixed wings (e.g., airplane). The Strouhal number is the ratio of the characteristic length of the object in the flow, multiplied by the frequency of the observed phenomenon (e.g., vortex; flapping wings) in reference to the velocity of the object with respect to the flow of the medium. The Strouhal number is a function of the Reynolds number, also dimensionless.
1883	Osborne Reynolds (1842–1912)	Friction description with respect to fluid dynamics concepts. Introduction of the Reynolds number defining the ratio of inertial force with respect to viscous forces. The Reynolds number provides a method to compare similar flow patterns under different fluid flow situations.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1889	Robert Manning (1816–1897)	Description of the average flow velocity for free-flow pipe flow based on the incline, and the radius of the pipe and fill area of the tube (jointly providing the wetted area, or hydraulic radius): Manning formula.
1895	Diederik Johannes Korteweg (1848–1941) and Gustav de Vries (1866–1934)	Diederik Korteweg and his student Gustav de Vries derived a nonlinear partial differential equation defining the propagation of waves in shallow water. The Korteweg–de Vries (KdV) equation describes the solitary wave described by John Scott Russell (1808–1882). The KdV equation has had an important implications for the development of the mathematical description of solitons.
1899	Jules Henri Poincaré (1854–1912) and Jacques Salomon Hadamard (1865–1963)	Geodesic flow; mathematical description and physical analysis. With further analysis by George David Birkhoff (1884–1944) in 1927.
1904	Ludwig Prandtl (1875–1953)	Description of the boundary layer for viscous flow, formed at the interface with a solid surface.
1905	Orville Wright (1871–1948) and Wilbur Wright (1867–1912)	First sustained flight with a powered fixed-wing aircraft.
1905	Vito Volterra (1860–1940)	Description of plastic deformation of ductile materials, describing the ability of solid materials to deform under tensile stress, using a theory of dislocations. One example is bending a metal coat hanger.
1907	Edgar Buckingham (1867–1940)	Description on the movement of soil moisture (“capillary action”), as well as gas diffusion in soil.
1910	Moritz Weber (1871–1951)	Analysis of multiphase flow at the boundary interface, in principle Weber compared the inertia of the fluid motion to the surface tension at the interface, described by the Weber number.
1915	Paul Richard Heinrich Blasius (1883–1970)	Description of the net force resulting from fluid flow applied to a fixed body submerged in the flow, using a complex velocity potential defining the flow. The solution of the Blasius theorem uses the Cauchy residue theorem (Augustin Louis de Cauchy [1789–1857]). Student of Ludwig Prandtl (1875–1953).
1923	Sir Geoffrey Ingram Taylor (1886–1975)	Combined contributions to fluid dynamics and wave theory, specifically in a convoluted form applied to vortex formation. Specific topics in his research were with respect to flow through porous surfaces and sheet flow. Taylor contributed to the development of the supersonic aircraft, ca. 1946.
1924	Theodore von Kármán (1881–1963)	Introduction of the Kármán vortex street concept. The Kármán vortex can result in resonance effect and Aeolian sound production.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1931	Georges Jean Marie Darrieus (1888–1979)	Introduction of the wind turbine.
1937	Sir Frank Whittle (1907–1996)	Introduction of the jet engine.
1944	Lewis Ferry Moody (1880–1953)	Friction computation and introduction of the Moody chart, plotting the roughness with respect to Reynolds number of flow and the Darcy–Weisbach friction factor defining the surface contact.
1947	Chuck Yeager (1923–)	Breaking of the sound barrier during level flight.
1957	Owen Martin Phillips (1930–2010), respectively John Wilder Miles (1920–2008)	Gravity wave with respect to either water surface (e.g., ocean waves) or wind flow direction (3D) or capillary wave concept. Theoretical description by means of Stokes wave or Airy wave formulation.
1981	Uri Dinnar (1939–2014)	Theoretical description of periodic turbulent and viscous (non-Newtonian) flow, specifically applicable to blood flow in large (compliant) vessels.

General

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
6000 BC–2000 BC	Stone Age	Mechanical labor and tool fabrication.
ca. 6000 BC		First recorded use of floatation devices: boats. This illustrated the Archimedes principle (Archimedes [287 BC–212 BC]), but no documented descriptions on the floatation principles from those days.
ca. 4000 BC		First recorded use of wheel for transportation.
ca. 3000 BC		Traceable use of a potter's wheel used for the construction of crockery.
3300 BC–1000 BC	Bronze Age	Smelting and forging of soft metals using low heat: copper, tin, gold. This age also introduces the written documentation.
1000 BC–700 AD	Iron Age	Higher heat requirements and more detailed tool manufacturing, introducing scientific and engineering challenges. Historical tracking of processes and developments and philosophies. Introduction of complicated mechanisms and requiring detailed analytical thinking.
ca. 600 BC	Thales of Miletus (ca. 624 BC–ca. 546 BC; known as Thales: Θαλῆς)	Introduction of metrology, measurements of the height of pyramids with proposed standards. Introduced the concept of logic proof.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
430 BC	Socrates (469 BC–399 BC)	Scholar and educator, introducing analytical thinking.
ca. 360 BC	Plato (427 BC–347 BC)	Student of Socrates (469 BC–399 BC). Founder of the principles for modern philosophy and science. The Plato school of teaching included, but not limited to, astronomy, biology, mathematics, philosophy, and political theory.
350 BC	Aristotle (384 BC–322 BC)	Student of Plato (427 BC–347 BC). Founder of the Lyceum school of analytical thinking in Macedonia. Aristotle described the initial concepts of physics, motion, time as well as astronomy concepts. Aristotle hypothesized an external horizontal force (acting during flight) perpetuating the projectile motion of a ballistic object, which is incorrect; only gravity forces the object downward.
ca. 250 BC	Archimedes (287 BC–212 BC)	Revealed the properties that define buoyancy. Developed calculus and algebra and created a system for “abbreviating” large numbers by means of what we now consider exponential expressions.
40 BC	Marcus Vitruvius Pollio [Vitruvius] (ca. 80 BC–10 BC)	Roman engineering architect and civil engineer. Vituvius served under Gaius Julius Caesar (100 BC–44 BC). In the army position he was also charged with the care of the infirmed, where he used early biomedical engineering approaches for novel diagnosis and treatment.
62	Hero of Alexandria [ῥων ὁ Ἀλεξανδρεὺς], (10–70)	Mathematician, physicist, and mechanical engineer who also taught pneumatics. A set of two books: <i>The Pneumatica</i> describes mechanical devices that work by air, steam, or water pressure. Also known as Heron of Alexandria. He invented a steam-powered engine called the “Æolipile.”
120	Claudius Ptolemy {Ptolemaeus} [Πτολεμαῖος] (90–168)	Geographic recordings of a significant part of the Islamic and western world (i.e., Roman and Persian Empire), living in Egypt, as a Roman with Greek education. His cartography extended all the way out, including parts of China (discovered in the fifteenth century). He specifically developed arithmetical techniques for calculating astronomical phenomena, under the teachings of Babylonian astronomers. Also known as: بطليموس (Batlaymus; Arabic).
644		Wind-powered devices developed by the Persians.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
771	Karel de Grote (742–815)	General scientific contributions as the ruler of the Netherlands and associated territories (stretching out over France to the Mediterranean and western Germany). Karel de Grote's scientific contributions, including chemical implementations [e.g., crop-growing circulation/alternation] and encouraged teaching of mathematics and scientific problem solving. Karel de Grote encouraged scientific and cultural engagement, during the period of the "Dark Ages (fourth to thirteenth century)" and his time is considered a predate to the "Renaissance" (fourteenth to seventeenth century), named the "Karolinger Renaissance," after Karel (English: Karl).
1500	Leonardo da Vinci (1452–1519)	The preverbal "Renaissance man," involved in all aspects of cultural evolution, science, engineering, politics, and art.
1503	Gregor Reisch (1467–1525)	Detailed outline of the state-of-the-art science and engineering knowledge to date, including human anatomical drawings in the publication <i>Margarita Philosophica</i> . The total works of Gregor Reisch form a series of 12 books compiling an encyclopedia describing topics ranging from Latin grammar, to dialectics, rhetoric, arithmetic, music, geometry, astronomy, physics, natural history, physiology, psychology, and ethics.
1512	Gregorius Reisch (1467–1525)	Introduction of the concept of the theodolite, used for topography and geographic location determination.
1543	Nicolaus Copernicus (1473–1543); Alias of Niclas Koppernigk	Introduction of the heliocentric model for the earth, Sun, and other planets. This follows the statement by the astronomer from Greece: Aristarchus of Samos (ca. 310–ca. 230 BC), made more than 1700 years prior. The scientific observations made by Copernicus were validated by Tycho Brahe (1546–1601) and Johannes Kepler (1571–1630).
1590	Francis Bacon, 1st Viscount of St. Alban (1561–1626)	Regulate the general scientific methodology.
ca. 1600	William Gilbert (1544–1603)	Experimentalist. Description of magnetism, in his work <i>De magnete, magnetisque corporibus, et de magno magnete tellure</i> . The compass had been in use since 206 BC (Chinese Han Dynasty: 206 BC–220 AD; maybe even earlier, during the Qin Dynasty: 221 BC–207 BC), in the European and Persian area since the thirteenth century.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 1600	Galileo Galilei (1564–1642)	Major contributor to the scientific revolution and the (re) introduction of analytical thinking in science, engineering, and general thought processes. Galileo Galilei was remanded under house arrest by the Roman Inquisition for his views and teachings where he died after 9 years. This was the trailing end of the Renaissance period.
1614	René Descartes (1596–1650)	Introduction to vortex motion. Introduction of the concept of general corpuscular motion, extending from small (maybe referring to the undefined atom), to planetary orbits. Descartes also made an illustration of the earth's magnetic field configuration in 1644, in his model the moon and celestial objects participated in the formation of the path of the magnetic field lines. Based on the limited experimental observations available in his time the premise was still not bad.
1632	Evangelista Torricelli (1608–1647)	Introduction of the barometer; essential in weather prediction; meteorology.
1650	Blaise Pascal (1623–1662)	Pascal's law, pressure in a container applies an equal force on all surface of the enclosure.
1660	Robert Boyle (1627–1691)	Gas laws, definition of the behavior of gases. Boyle mentioned the compression of gas as a potential “shock-absorber,” acting similar to a spring.
1673	Christiaan Huygens (1629–1695)	Construction of a “combustion engine” powered by gun powder. Huygens introduced several concept of mechanical engineering and described the mechanism of shock waves. Christiaan Huygens is most known for his lens manufacturing and optical design of telescopes. The mathematical efforts of Christiaan Huygens in probability theory were far advanced and he collaborated with the mathematician Pierre de Fermat (1601–1665) from France.
1679	Denis Papin (1647–ca. 1712)	Pressure and thermodynamic and mechanical impacts.
1680	Robert Hooke (1635–1703)	Force applied by a compressed spring.
ca. 1687	Sir Isaac Newton (1643–1727)	Sir Isaac Newton introduced several laws of motion. The publication of the <i>Philosophiæ Naturalis Principia Mathematica</i> provides detailed definitions regarding ballistic motion, circular motion (centripetal force), laws of action–reaction, gravitational acceleration, inertia, and force with respect to acceleration. Introduction of the three laws of motion.
1698	Thomas Savery (1650–1715)	Construction of the basic steam engine; using information obtained by Denis Papin (1647–ca. 1712).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1705	Edmond Halley (1656–1742)	Discovery of, and mathematical description of the trajectory for “Halley’s comet.”
1712	Thomas Newcomen (1664–1729)	Construction of a “atmospheric” steam engine.
1714	Brook Taylor (1685–1731)	Fundamental frequency of vibration; string. Additional work on pure mathematics: Taylor series.
1727	Leonard Euler (1707–1783)	Introduction of the concept of the elastic modulus, experimentally verified by Giordano Riccati (1709–1790) in 1782 and mathematically introduced by Thomas Young (1773–1829) in 1807, now known as Young’s modulus.
1732	Anders Celsius (1701–1744)	Thermometer scale calibration based on pure water phases.
1733	Daniel Bernoulli (1700–1782)	Acoustics, mechanical vibrations, and fluid dynamic principles introduced. Definition of the fundamental frequency and higher harmonics with supporting elaborate mathematical analysis (solutions to differential equations).
1735	Daniel Gabriel Fahrenheit (1686–1736)	Temperature scale in Fahrenheit based on body temperature and saltwater phases.
1743	Jean-Baptiste le Rond d’Alembert (1717–1783)	Publication on the concepts of forces and accelerating systems: <i>Traite de Dynamique</i> .
1752	Benjamin Franklin (1706–1790)	Kite experiment and the documentation of “electric current.”
1757–1769	James Watt (1736–1819)	Modern steam engine design and operation with theoretical description of operation.
1762	Joseph Black (1728–1799)	Realization of the concept of latent heat.
1769	Nicolas-Joseph Cugnot (1725–1804)	First operational steam-powered automobile, the predecessor to the internal combustion automobile.
1781	Charles-Augustin de Coulomb (1736–1806)	Definition of the electric field related to electric charge. The electric charge itself was still an elusive concept in those days.
1783	Antoine Laurent de Lavoisier (1743–1794)	Discovery of oxygen and the chemical impact.
1783	Joseph-Michel Montgolfier (1740–1810) and Jacques-Étienne Montgolfier (1745–1799)	Hot-air balloon; buoyancy.
1785	Jacques Alexandre César Charles (1746–1823)	Charles’s law, expansion of gases.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1800	Count Alessandro Giuseppe Antonio Anastasio Volta (1745–1827)	Introduction of the battery.
1802	Joseph Louis Gay-Lussac (1778–1850)	Ideal gas law; building on the work by Robert Boyle (1627–1691), more than a century earlier.
1807	Thomas Young (1773–1829)	Formal introduction of the Young's modulus for elastic deformation, tying strain to stress, based on the work by Leonard Euler (1707–1783).
1821	Michael Faraday (1791–1867)	Discovery of electromagnetic rotation, leading to his law on electromagnetic induction in 1831. Meanwhile, in 1923 Michael Faraday experimentally verified the concept of refrigeration, introduced based on the work of John Dalton (1766–1844) in 1802 and William Cullen (1710–1790) in 1756.
1823	Nicéphore Niépce (1765–1833) and Louis Jacques-Mandé Daguerre (1787–1851)	Introduction of photography, using the earlier efforts of Albertus Magnus (1193–1280) with his discovery of silver nitrate, and Georg Fabricius (1516–1571) who discovered silver chloride.
1824	Nicolas Léonard Sadi Carnot (1796–1832)	Refrigerator for general public.
1827	Benoît Fourneyron (1802–1867)	First water turbine.
1831	Michael Faraday (1791–1867) and Joseph Henry (1797–1878)	Law of induction, leading to the development of the electric generator.
1840	Jean Léonard Marie Poiseuille (1799–1869) and Gotthilf Heinrich Ludwig Hagen (1797–1884)	Pressure drop for incompressible fluids with respect to laminar flow.
1848	William Thomson, 1st Baron Kelvin (i.e., Lord Kelvin) (1824–1907)	Absolute temperature scale: Kelvin.
1851	Jean Bernard Léon Foucault (1819–1868)	Foucault pendulum, illustrating the impact of the earth's rotation on motion.
1852	James Prescott Joule (1818–1889) and William Thomson, 1st Baron Kelvin {Lord Kelvin} (1824–1907)	Joule–Thomson effect: rapidly expanding gas leads to a reduction in the temperature of the gas, even offering the potential for a phase change to solid, or liquid. Sometimes also found as the Joule–Kelvin effect.
1854	Robert Wilhelm Eberhard Bunsen (1811–1899)	Bunsen burner.
1859	James Clerk Maxwell (1831–1879)	Description of the distribution law of molecular velocities, also relating to the concept of Brownian motion.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1861	Augustin Mouchot (1825–1911)	Presentation of the use of solar energy as a source for personal energy consumption.
1866	Ludwig Eduard Boltzmann (1844–1906) and Josiah Willard Gibbs (1839–1903)	Statistical mechanics, correlating energy, and heat, to the movement (velocity).
1873	Josiah Willard Gibbs (1839–1903)	Chemical potential, a energy constituent within the Gibbs free energy. Thermodynamic concept describing the energy that can be released or absorbed during a chemical reaction.
1873	James Clerk Maxwell (1831–1879)	Theory of electromagnetic radiation: <i>Treatise on Electricity and Magnetism</i> . James Maxwell made use of the prior work by Wilhelm Eduard Weber (1804–1891) and Johann Carl Friedrich Gauss {Gauß} (1777–1855).
1880	Johannes Diederik van der Waals (1837–1923)	Description of the covalent bond. Van der Waals equation.
1887	Heinrich Rudolf Hertz (1857–1894)	Radar development. Detection of electromagnetic radiation (radio waves). Heinrich Hertz also discovered that certain metal plates will generate electricity when exposed to light: photoelectric effect.
1894	Max Karl Ernst Ludwig Planck (1858–1947)	Black body radiation.
1895	Wilhelm Röntgen (1845–1923)	Discovery of X-ray (Röntgen rays).
1897	Joseph John Thomson (1856–1940)	Discovery of the electron; using William Crookes's vacuum tube.
1897	Guglielmo Marconi, 1st Marquis of Marconi (1874–1937)	Introduction of wireless communications and radio.
1896	Manya (Marie) Skłodowska Curie (1867–1934)	General discovery of the concept of radiation and the various levels of energy, particulate and electromagnetic radiation involved in certain decay processes. Discoveries were made with the help of an electrometer that was developed approximately 15 years earlier by her husband Pierre Curie (1859–1906) and his brother Jacques Curie (1856–1941). The first radioactive element they discovered was uranium.
1898	Antoine Henri Becquerel (1852–1908)	Introduction of units for radioactivity radiation. Collaborator with Manya (Marie) Skłodowska Curie (1867–1934). Henri Becquerel, Marie Curie, and Pierre Curie shared the Nobel Prize in Physics for their radioactivity discoveries in 1903.
1900	Ferdinand Adolf Heinrich August Graf von Zeppelin (1838–1917)	Successful dirigible, gas-filled air floatation device with propulsion.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1900	Max Karl Ernst Ludwig Planck (1858–1947)	Inception of quantum mechanics.
1905	Albert Einstein (1879–1955)	Theory of special relativity: relationship between space and time. (1) The laws of physics are invariant in any and all inertial systems, based on a nonaccelerating frame of reference configuration and (2) the speed of light in vacuum is the identical to all observers, regardless of the motion of the frame of reference for the light source. The theory is “special” since it applies to the special case of inertial reference frames.
1913	Niels Henrik David Bohr (1885–1962)	Bohr atomic model.
1916	Albert Einstein (1879–1955)	Theory of general relativity: geometric theory of gravitation. The “general” aspect defines the unified description of gravity as a geometric property of both space and time, also referred to as “space-time.” In particular, the curvature of space-time is uniquely related to the momentum and energy of any kind of matter and radiation that are present.
1923	Lester Halbert Germer (1896–1971) and Clinton Joseph Davisson (1881–1958)	Experimental confirmation of the wave–particle duality for electromagnetic radiation.
1926	Erwin Schrödinger (1887–1961)	Quantum mechanical wave equivalence, wave theory for atomic and nuclear energy configurations.
1926	Mark Cowley Lidwell (1878–1969) and Edgar Harold Booth (1893–1963)	Rudimentary, but effective, external cardiac pacemaker design.
1927	Werner Karl Heisenberg (1901–1976)	Uncertainty principle; impossibility to know both the location and the momentum (energy) of a system with absolute accuracy simultaneously. This also removed the causality aspect from events, and substitutes probabilistic distributions.
1930	Richard Buckminster Fuller (1895–1983)	Mechanical engineering and engineering architecture, as well as chemistry; bucky-ball, multipoint connections in both chemical structures and mechanical structures.
1931	Georges Jean Marie Darrieus (1888–1979)	Introduction of the wind turbine.
1940+	Julius Robert Oppenheimer (1904–1967)	Manhattan project: fission reaction. Prominent members: Arthur Compton (1892–1962); Enrico Fermi (1901–1954), Eugene Wigner (1902–1995), and dozens more. One notable result is the creation of nuclear power plants.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1937–1959	Chester Floyd Carlston (1906–1968)	Photocopy machine, patented in 1942. The first photocopier was offered for sale by the Haloid company in 1959, later renamed Xerox.
1948	Julian Schwinger (1916–1994), Richard Phillips Feynman (1918–1988), and Sin-Itiro Tomonaga (1906–1979)	Quantum electrodynamics and quantum field theory.
1950	John Alexander Hopps, (1919–1998)	Introduction of the “portable” (45 kg) cardiac pacemaker, based on the earlier work by Mark Lidwell (1878–1969) and Edgar Harold Booth (1893–1963) in 1926. This led, with the development of microprocessors, to the first implantable pacemaker in 1958 by William Chardack (1919–2011) and Wilson Greatbatch (1919–2011).
1956	Paul Winchell {Wilchinsky} (1922–2005)	Artificial heart (Jarvik 7).
1969		First lunar landing; Apollo 11: Neil Armstrong (1930–2012), Michael Collins (1930–) (commander of lunar orbitor module), and Buzz Aldrin {Edwin Eugene Aldrin Jr} (1930–).
1968	Stephen Hawking (1942–), George Francis Rayner Ellis (1939–), and Roger Penrose (1931–)	“Big Bang theory” for the origin of the universe as we know it and how we observe the physical parameters evolve. The concept was introduced by Edwin Hubble (1889–1953) in rudimentary form in 1929.
2008	CERN, Switzerland	Large Hadron Collider, beginning of operations. To date no evidence supporting string theory or supersymmetry has been collected.
2012	François Baron Englert (1932–) and Peter Ware Higgs (1929–)	Higgs boson (126 GeV) discovery in the Large Hadron Collider at CERN, Geneva, Switzerland.

Geo

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 600 BC	China; India	Documented use of magnetic compasses; the lodestone. More specific documented use dates to the Han Dynasty (ca. 206 BC).
ca. 600 BC	Thales of Miletus (ca. 624 BC–ca. 546 BC; known as Thales: Θαλῆς)	Introduction of metrology, accurate measurements of objects, phenomena, events, and conditions (e.g., atmospheric conditions).
430 BC	Socrates (469 BC–399 BC)	Scholar and educator, introducing analytical thinking.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
350 BC	Aristotle (384 BC–322 BC)	Aristotle described the initial concepts of physics, motion, time as well as astronomy concepts. Aristotle used geological and atmospheric record keeping for the prediction of weather conditions (meteorology). First documented use of a scientific approach to weather forecasting.
ca. 250 BC	Archimedes (287 BC–212 BC)	Revealed the properties that define buoyancy. The base principles relate to the tectonic plate mechanics.
ca. 240 BC	Eratosthenes (ca. 276 BC–ca. 195 BC)	Derivation of the circumference of the earth using trigonometry (round earth was already a concept).
50	Gaius Plinius Secundus (23–79), known as: Pliny the Elder	Publication of the magnetic action of the lodestone in his publication: <i>Naturalis Historia</i> . A rather detailed description of the use of magnetism for geographical location determination is described.
62	Hero of Alexandria [ῥων ὁ Ἀλεξανδρεὺς] (10–70)	Mathematician, physicist, and mechanical engineer who also taught pneumatics. The base of this methodology formed the principle understanding of the movement of atmospheric air masses in future years.
120	Claudius Ptolemy {Ptolemaeus} [Πτολεμαῖος] (90–168)	Geographic recordings of a significant part of the Islamic and western world (i.e., Roman and Persian Empire), living in Egypt, as a Roman with Greek education. His cartography extended all the way out, including parts of China (discovered in fifteenth century). He specifically developed arithmetical techniques for calculating astronomical phenomena, under the teachings of Babylonian astronomers. Also known as: بطليموس (Batlaymus; Arabic). Combining the cartography with the ancient Chinese knowledge of the earth's magnetic field formed early recording of the location of the North and South pole, however rudimentary, only a portion of the earth had been mapped. later documentation with a detailed world map provided an indication of the migration of the magnetic poles.
ca. 132	Zhang Heng (78–139) of China's Han dynasty	Documented construction and operation of the first seismic instrument.
ca. 1000	Abu al-Rayhan al-Biruni (973–1048)	Documented hypothesis of the movement of the tectonic plates, specifically the assumed location of India, which in early history would have been ocean. Realistically: continental drift split the continents from one “continuous” land mass about 200 million years ago, end of Paleozoic era; which is often considered to hold the beginning of animal life.
1,050		Full-scale use of the compass for geographical orientation in the western and far-eastern world.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1,269	Petrus Peregrinus of Maricourt	Formal description of the use of the compass during seafaring expeditions.
1500	Leonardo da Vinci (1452–1519)	The preverbal “Renaissance man,” involved in all aspects of cultural evolution, science, engineering, politics, and art.
1535	Joao de Castro (1500–1548)	Recognition of the deviation between the magnetic north and the geographic north.
1543	Nicolaus Copernicus (1473–1543); alias of Niclas Koppernigk	Introduction of the heliocentric model for the earth, sun, and other planets. This follows the statement by the astronomer from Greece: Aristarchus of Samos (ca. 310–ca. 230 BC), made more than 1700 years prior. The scientific observations made by Copernicus were validated by Tycho Brahe (1546–1601) and Johannes Kepler (1571–1630).
1590	Francis Bacon, 1st Viscount of St. Alban (1561–1626)	Regulate the general scientific methodology.
ca. 1600	William Gilbert (1544–1603)	Experimentalist. Description of magnetism, in his work <i>De magnete, magnetisque corporibus, et de magno magnete tellure</i> . The compass had been in use since 206 BC (Chinese Han Dynasty: 206 BC–220 AD; maybe even earlier, during the Qin Dynasty: 221 BC–207 BC), in the European and Persian area since the thirteenth century.
ca. 1540		Realization that the magnetic field line running “north to south” (isogones) are not straight lines, but have complex tracks, even loops as a function of the geographical locations. Confirmed by Willem van Bemmelen (1868–1941) based on the magnetic direction recording made by the ships as a function of geographical location traveling for the East India Company (mercantile trips to the Dutch colonies), between the Netherlands and Indonesia (around Cape Horn, South Africa).
ca. 1600	Galileo Galilei (1564–1642)	Major contributor to the scientific revolution and the (re) introduction of analytical thinking in science, engineering, and general thought processes. Galileo Galilei was remanded under house arrest by the Roman Inquisition for his views and teachings where he died after 9 years. This was the trailing end of the Renaissance period.
1614	René Descartes (1596–1650)	Introduction to vortex motion. Introduction of the concept of general corpuscular motion, extending from small (maybe referring to the undefined atom), to planetary orbits. Vortices are found in geological phenomena such as cyclones (hurricanes), maelstrom, and aspects of magma flow.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 1650	Pierre de Fermat (1601–1665)	Developed infinitesimal (elementary) calculus. Instrumental in the development of the mathematical description of the wave refraction principle. Several of Fermat's mathematical efforts in solving polynomial equations extended beyond the two-dimensional plane where most mathematicians were comfortable, which has direct implications in seismic wave propagation, although not investigated in his day to great extent.
ca. 1655	Christiaan Huygens (1629–1695)	Invention of a clockwork mechanism capable of timekeeping while at sea in order to allow for accurate geographical measurements.
1650	Blaise Pascal (1623–1662)	Pascal's law, pressure in a container applies an equal force on all surface of the enclosure. The unit for pressure under atmospheric conditions uses the unit Pascal in his honor.
1660	Robert Boyle (1627–1691)	Gas laws, definition of the behavior of gases. Boyle mentioned the compression of gas relating to partial pressure of atmospheric constituents and barometric values.
1679	Denis Papin (1647–ca. 1712)	Pressure and thermodynamic and mechanical impacts. Denis Papin worked as an assistant to both Christiaan Huygens (1629–1695) and Robert Boyle (1627–1691). His invention of the pressure cooker bears some resemblance to the conditions found in geysers.
1680	Robert Hooke (1635–1703)	Force applied by a compressed spring. The extended implications are in the mechanics of seismic waves.
ca. 1687	Sir Isaac Newton (1643–1727)	The recognition of gravitational force provided one of the essential building blocks in the geological understanding next to.
1705	Edmond Halley (1656–1742)	Discovery of, and mathematical description of the trajectory for "Halley's comet."
1724	George Graham (1675–1751)	Recognition of the concept of diurnal declination, compass needle during the day.
1750–1800		With the advent of more sophisticated measurement instrumentation (thermometer, barometer, wind velocity meter) meteorology became more scientifically rooted, especially with the interest of a broad range of mathematicians in the dynamics of physics; thermodynamics, motion, wave propagation, and pressure perturbations. The methodology for cartography and for geographic orientation (compass) also had evolved significantly.
1714	Brook Taylor (1685–1731)	Fundamental frequency of vibration; string. Additional work on pure mathematics: Taylor series.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1727	Leonard Euler (1707–1783)	Introduction of the concept of the elastic modulus, experimentally verified by Giordano Riccati (1709–1790) in 1782 and mathematically introduced by Thomas Young (1773 – 1829) in 1807, now known as Young's Modulus.
1732	Anders Celsius (1701–1744)	Thermometer scale calibration based on pure water phases.
1733	Daniel Bernoulli (1700–1782)	Acoustics, mechanical vibrations, and fluid dynamic principles introduced. Definition of the fundamental frequency and higher harmonics, with supporting elaborate mathematical analysis (solutions to differential equations). This laid the foundation for seismic imaging using P-wave (primary wave; longitudinal) and S-wave (secondary wave, or shear wave [transverse]).
1735	Daniel Gabriel Fahrenheit (1686–1736)	Temperature scale in Fahrenheit based on body temperature and saltwater phases.
1743	Jean-Baptiste le Rond d'Alembert (1717–1783)	Publication on the concepts of forces and accelerating systems: <i>Traite de Dynamique</i> .
1752	Benjamin Franklin (1706–1790)	Kite experiment and the documentation of “electric current.”
ca. 1755	Piter van Musschenbroek (1692–1761)	Study of the deviations in the earth's magnetic field lines as a function of altitude, no conclusive data at the time.
1757–1769	James Watt (1736–1819)	Modern steam engine design and operation with theoretical description of operation.
1762	Joseph Black (1728–1799)	Realization of the concept of latent heat.
1769	Nicolas-Joseph Cugnot (1725–1804)	First operational steam-powered automobile, the predecessor to the internal combustion automobile.
1781	Charles-Augustin de Coulomb (1736–1806)	Definition of the electric field related to electric charge. The electric charge itself was still an elusive concept in those days.
1783	Antoine Laurent de Lavoisier (1743–1794)	Discovery of oxygen and the chemical impact.
1783	Joseph-Michel Montgolfier (1740–1810) and Jacques-Étienne Montgolfier (1745–1799)	Hot-air balloon; buoyancy.
1785	Jacques Alexandre César Charles (1746–1823)	Charles's law, expansion of gases.
1800	Count Alessandro Giuseppe Antonio Anastasio Volta (1745–1827)	Introduction of the battery.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1802	Joseph Louis Gay-Lussac (1778–1850)	Ideal gas law; building on the work by Robert Boyle (1627–1691), more than a century earlier.
1807	Thomas Young (1773–1829)	Formal introduction of the Young's modulus for elastic deformation, tying strain to stress, based on the work by Leonard Euler (1707–1783). The Young's modulus plays a significant role in the seismic activity and mechanical deformation as well as the seismic wave propagation in three-dimensional geometry.
1810	Siméon Denis Poisson (1781–1840)	Poisson's analysis of the wave theory of light contributed to the evolution and understanding of interference principles and applications.
1811	Siméon Denis Poisson (1781–1840)	Introduction of the means to quantify the ratio of transverse to axial strain, by means of the Poisson ratio.
1820	William George Horner (1786–1837)	Introduction of the methodology for solving and calculating polynomials (roots): Horner's method. The methods were actually already described 600 years prior by the Chinese mathematician Qin Jiushao (秦九韶), (ca. 1202–1261).
ca. 1825	Baron Augustin-Louis Cauchy (1789–1857)	Pioneer in mathematical and structural analysis of data. Formally introduced several of the modern concepts of calculus. Cauchy also introduced the concept of convergent series, in order to obtain a finite solution.
1840	Jean Léonard Marie Poiseuille (1799–1869) and Gotthilf Heinrich Ludwig Hagen (1797–1884)	Pressure drop for incompressible fluids with respect to laminar flow. Reference to meteorology, wind formation based on arctic versus topical pressure systems.
1842	James David Forbes (1809–1868)	Measurement of seismic wave with the first seismometer, using a weight hanging from springs. Modern seismometers generally measure vibration amplitude in the frequency range from 0.00118 Hz to 500 Hz. The scale (Richter scale) of the seismic activity was introduced by Charles Francis Richter (1900–1985) and Beno Gutenberg (1889–1960) in 1935.
1843–1848	James Prescott Joule (1818–1889)	Empirical verification of the first law of thermodynamics: stating the equivalence of heat and work. This applies to both the source energy for the persisting liquid core (magma) and the work performed by volcanic eruptions and earthquakes.
1848	William Thomson, 1st Baron Kelvin (i.e., Lord Kelvin) (1824–1907)	Absolute temperature scale: Kelvin. Reference base for geological events and meteorology.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1850	Rudolf Julius Emanuel Clausius (1822–1888)	Recognition of two basic principles of thermodynamics, later introduced by means of the first and second law of thermodynamics, respectively: energy is constant and entropy tends toward a maximum. Clausius introduced the parameter U , representing the internal energy. Publication of book <i>On the Motive Power of Heat, and on the Laws Which Can Be Deduced from It for the Theory of Heat</i> . Clausius introduced what is now regarded the second law of thermodynamics in 1865 (referred to by William John Macquorn Rankine [1820–1872] as the “thermodynamic function”), as part of any natural thermodynamic process, the sum of the entropies of the participating systems will increase.
1851	Jean Bernard Léon Foucault (1819–1868)	Foucault pendulum, illustrating the impact of the earth’s rotation on motion.
1851	Sir George Gabriel Stokes, 1st Baronet (1819–1903)	Creeping flow, partially applicable to seismology, specifically in the treatment of the mathematical solution for tsunami seismic waves. Specific seismic work of Gabriel Stokes was on a “microscopic” scale in earth-sized dimensions, describing vibrational forces and energy related to driven oscillations while crossing bridges, and the resulting bridge collapses in his days. One of the fall-outs from the bridge vibration and collapse is development of studies in metal fatigue. Furthermore, the work of Stokes contributed to the development of the scientific and engineering support for the construction of high-rise buildings in earthquake-prone geographical regions.
1852	James Prescott Joule (1818–1889) and William Thomson, 1st Baron Kelvin {Lord Kelvin} (1824–1907)	Joule–Thomson effect: rapidly expanding gas leads to a reduction in the temperature of the gas, even offering the potential for a phase change to solid or liquid. Sometimes also found as the Joule–Kelvin effect. The Joule–Thomson effect is an isenthalpic process, which entails that the enthalpy of the fluid is constant during the process, which applies to Joule–Thomson inversion temperature, described in the Linde cycle (Carl von Linde [1842–1934]), offering conditions leading to cloud formation.
1859	James Clerk Maxwell (1831–1879)	Description of the distribution law of molecular velocities.
1861	Augustin Mouchot (1825–1911)	Presentation of the use of solar energy as a source for personal energy consumption.
1865	Gabriel Lamé (1795–1870)	Introduction of the shear modulus and another parameter that is linked through the Poisson ratio (Lamé constants), providing the basis for the introduction of the P-wave and S-wave principles, based on the work of Robert Hooke (1635–1703).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1868	Sultan – Abdülaziz (1830–1876) and Grand Vizier: Mehmed Emin Aali Pasha (1815–1871)	Installation of the “first” geophysical and meteorological observatory: “Rasathane-i Amire” in Constantinople (Istanbul, Turkey): Ottoman Empire.
1873	James Clerk Maxwell (1831–1879)	Theory of electromagnetic radiation: <i>Treatise on Electricity and Magnetism</i> . James Maxwell made use of the prior work by Wilhelm Eduard Weber (1804–1891) and Johann Carl Friedrich Gauss {Gauß} (1777–1855)
1885	John William Strutt, the 3rd Baron Rayleigh (1842–1919)	Introduction of the concept of surface seismic waves. Specifically the surface interface waves, referred to as Rayleigh waves (single surface only), the medium can be of semi-infinite thickness. Also found described under finite thickness plate conditions by Lamb waves (Sir Horace Lamb [1849–1934]).
1887	Heinrich Rudolf Hertz (1857–1894)	Radar development. Detection of electromagnetic radiation (radio waves). Heinrich Hertz also discovered that certain metal plates will generate electricity when exposed to light: photoelectric effect.
1896	Emil Johann Wiechert (1861–1928)	Introduction and verification of the layered model for earth. Emil Johann Wiechert was a pupil of Woldemar Voigt (1850–1919). Emil Wiechert also developed a detailed mathematical model for the seismic activity on earth, with assistance from Beno Gutenberg (1889–1960).
1897	Joseph John Thomson (1856–1940)	Discovery of the electron. The beta particle is one of three decay process that allows for molecular identification and quantification of radioactive activity over time to build a history profile of the geological development processes.
1900	Ludwig Eduard Boltzmann (1844–1906)	Thermodynamic concepts with respect to heat exchange in the earth’s volume, specifically defining the entropy. Boltzmann equation for statistical mechanics, introduced by Ludwig Boltzmann between 1872 and 1875, reformulated by Max Karl Ernst Ludwig Planck (1858–1947). For certain systems also addressed as the Gibbs entropy formula, after Josiah Willard Gibbs (1839–1903).
1902	Maurits Snellen	Discovery of the influence of solar activity on the magnetic field lines used for compass orientation (isogones), sunspots.
1905	Albert Einstein (1879–1955)	Alternate theory of gravity, and his theories of relativity shaped the developing field of relativistic astrophysics.
1911	Augustus Edward Hough Love (1863–1940)	Introduction of the “Love wave”; horizontally polarized (elastic) shear waves (SH waves) in a subsurface layer of semi-infinite dimensions, covered by a finite thickness cover layer. These wave will travel faster than Rayleigh waves, which occur in the surface layer.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1912	Alfred Wegener (1880–1930)	Revelation of the tectonic plate concept and description of continental drift.
1910–1935	Alfred Wegener (1880–1930), Maurice Ewing (1906–1974), Bryan L. Isacks (1942?–), Walter C. Pitman, III (1931–), Frederick Vine (1939–), Drummond H. Matthews (1931–1997), S. Keith Runcorn (1922–1995), Xavier Le Pichon (1937–), Harry Hammond Hess (1905–1969), Robert S. Dietz (1914–1995), V. Hugo Benioff (1899–1968), Dan McKenzie (1942–), Edward Bullard (1907–1980), John Tuzo Wilson (1908–1993), and W. Jason Morgan (1935–)	Development and refinement of the tectonic plate model.
1914	Beno Gutenberg (1889–1960)	Confirmation of the layered model for the structure of the earth globe, introduced by his mentor Emil Johann Wiechert (1861–1928).
1917	Sir Horace Lamb (1849–1934)	Introduction of the concept of evanescent waves, referred to as Lamb waves. Elastic waves traveling in the bulk of a finite thickness plate (i.e., tectonic plate).
1919		The observations made during a total solar eclipse in this year by an expedition from the Royal Astronomical Society and the Royal Society of London confirmed the deviation of starlight in the gravitational field of the sun as predicted by the general theory of relativity. The strongest support for this theory came later from the agreement between the calculated and observed values of the precession of the perihelion of Mercury.
1922	Jacob Aall Bonnevie Bjerknes (1897–1975), Vilhelm Friman Koren Bjerknes (1862–1951), Halvor Skappel Solberg (1895–1974), and Tor Bergeron (1891–1977)	Formulation of pressure fronts and the general movement of air masses.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1924	Robert Stoneley (1894–1976)	Stoneley wave, Rayleigh wave-type interface wave, at a solid-solid interface, traveling with relatively high amplitude. In case the interface is solid-liquid the wave phenomenon is referred to as the Scholte wave (Johan Gerard Jozef Scholte [1907–1970]). Stoneley waves can be reflected and refracted at sharp impedance contrasts at interfaces such as lithology, fractures, and changes in borehole diameter. Moreover, as formation permeability increases, the propagation velocity for Stoneley wave decreases, resulting in dispersion.
1924	Edward Victor Appleton (1892–1965), Arthur Edwin Kennelly (1861–1939) next to Oliver Heaviside (1850–1925)	Initiation of a series of experiments that established the existence and properties of ionized layers in the upper atmosphere. The existence of this type of layers had been postulated by Arthur Edwin Kennelly (1861–1939) in 1902 and, independently, by Oliver Heaviside (1850–1925) to explain the observed implications for long-distance wireless telegraphy. Edward Appleton received the Nobel Prize for Physics in 1947.
1930	Jacob Clay (1882–1955)	Discovery that cosmic ray intensity decreased in going toward the geomagnetic equator. This latitude effect was investigated exhaustively by Arthur Holly Compton (1892–1962), Robert Andrews Millikan (1868–1953), and others.
1932	Victor Hugo Benioff (1899–1968)	Instrument development leading to the monitoring of the movement of the tectonic plates: Benioff seismograph. Additional instrumentation developed by Hugo Benioff is also capable of measuring strain in the earth's upper layer.
1935	Charles Francis Richter (1900–1985) and Beno Gutenberg (1889–1960)	Introduction of the Richter scale for the determination of the magnitude of seismic activity (earthquake). The scale has a base-10 logarithmic foundation. Prior to the Richter scale earthquakes were defined based on their destructive legacy, primarily pertaining to size of structures affected.
1936	Inge Lehmann (1888–1993)	Description of the numerical assessment of data obtained during earthquakes (seismological data) and the image formation of the structure of the earth's structure, divided in shells with different material phase and composition. The image formation is based on what is referred to as S-waves and P-waves. Inge Lehmann discovered and described the shape, size, and composition (rudimentary) of the earth's inner core.
1938	Guy Stewart Callendar (1898–1964)	Description of the concept of global warming resulting from the insulating layer of carbon dioxide exhaust in the atmosphere.
1942; 1947	Johan Gerard Jozef Scholte (1907–1970)	Scholte wave, seismic-type wave that has the characteristics of a Rayleigh wave, but is at the interface between a solid and a liquid, or a solid and an elastic (plastic) solid (e.g., sand).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1950		Dedicated studies initiated to observe the developing global warming concepts.
1953	William Maurice Ewing (1906–1974) and Bruce Charles Heezen (1924–1977)	Discovery of the Great Global Rift: oceanic ridge.
1960		Launch of the first weather satellite.
1995	Roger Lee Easton (1921–2014)	Development of the global positioning concept (GPS).

High Energy

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
13.8 billion years BC	Georges Henri Joseph Édouard Lemaître (1894–1966) and Edwin Powell Hubble (1889–1953)	“The Big Bang”; in 1927 the expanding universe was recognized.
1870	Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Unofficial introduction to the mechanism of action for nuclear fusion.
1896	Wilhelm Conrad Röntgen (1845–1923)	Discovery of X-ray radiation.
1896	Henri Becquerel (1852–1908)	Emission of “Becquerel rays” from uranium salts, later identified as alpha particles. Becquerel already recognized that this emission was different from X-ray since it was deflected by means of an applied external magnetic field. Conceptual introduction to the field of radioactivity.
1897	Joseph John Thomson (1856–1940)	Discovery of the electron; using William Crookes’s vacuum tube.
1897	Marie Skłodowska-Curie (1867–1934)	Discovery of radioactive isotopes. Marie Curie introduced the term “radioactivity.”
1899	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Emission of alpha particle.
1900	Max Karl Ernst Ludwig Planck (1858–1947) and James Clerk Maxwell (1831–1879)	Formal description of the photon and the energy associated with the electromagnetic wave.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1903	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Discovery of the nuclear decay half-life.
1903	Marie Skłodowska-Curie (1867–1934) and Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Quantification of nuclear decay.
1906	Dmitri Ivanovich Mendeleev (1834–1907)	Periodic Table of Elements.
1908	Johannes Geiger (1822–1945) and Ernest Rutherford (1871–1937)	Development of the Geiger counter, used to measure radioactive radiation.
1909	Francis Aston (1877–1945)	Mass spectrometer mass separation of closely separated isotopes. Highly sensitive mass spectrometer design.
1911	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Rutherford scattering on nuclear level, indication of the existence of the proton. The proton itself was not mentioned until 1932, this time again by Ernest Rutherford.
1912	Victor Francis Hess (1883–1964)	Recognition of high-energy cosmic radiation, observed during a high altitude balloon ride.
1913	Niels Henrik David Bohr (1885–1962)	Bohr atomic model.
1913	Frederick Soddy (1877–1956)	Formal introduction of the isotope concept.
1914	Niels Henrik David Bohr (1885–1962)	Description of the atomic energy layer model; hydrogen (Bohr atomic model).
1915	Ernest Marsden	Artificial transmutation, associated with radon enclosed by vacuum.
1918	Paul Scherrer (1890–1969)	X-ray diffraction, crystal structure. Nuclear energy development. Established the CERN institute in Switzerland as one of the founders. Directed the construction of the first cyclotron in 1940.
1919	Ernest Rutherford (1871–1937)	Artificial transmutation, hydrogen formation resulting from collisions of alpha particles with nitrogen, also generating oxygen and gamma rays.
1921	James Chadwick (1891–1974) and Étienne Samuel Biéler (1895–1929)	Strong nuclear force.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1923	Arthur Holly Compton (1892–1962)	Description of the deflection of photons by a charge unit, generally an electron, potentially the nucleus: Compton effect.
1925	Johannes Geiger (1822–1945) and Walther Wilhelm Georg Bothe (1891–1957)	Conservation of energy for atomic and nuclear processes.
1925	Werner Karl Heisenberg (1901–1976)	Uncertainty principle.
~1925		Recognition of the “Coulomb barrier” in nuclear collision, providing a “tunneling” effect for the release of alpha particles.
1927	Werner Karl Heisenberg (1901–1976)	Quantum uncertainty principle.
1927	Paul Adrien Maurice Dirac (1902–1984)	Description of antimatter.
1928	Johannes Geiger (1822–1945) and Walther Müller (1905–1979)	Introduction of an improved Geiger counter: the Geiger–Müller counter, using ionization of a confined gas.
1929	Leo Szilard (1898–1964) and Ernest Orlando Lawrence (1901–1958)	Particle accelerator, cyclotron. The cyclotron can accelerate protons to reach kinetic energy in excess of 700 MeV, with respective radius of 4.6 meter (1946). The first cyclotron was built in 1932, at the University of California Berkeley, California: Tevatron. Cyclotrons are specifically and not exclusively used to create isotopes for use in nuclear medicine, in particular for imaging (e.g., PET) and for cancer treatment.
1930	Walther Wilhelm Georg Bothe (1891–1957) and his student Herbert Becker ()	Observation of a puzzling penetrating “radiation” from beryllium bombarded with alpha particles (helium nuclei). Conceptual introduction to the fission process.
1931	Wolfgang Ernst Pauli (1900–1958)	Introduction of an electrically neutral particle, the neutron. Energy when involved in beta decay up to 0.5 MeV. The experimental verification of the existence of the neutrino was not until 1956 by Frederick Reines (1918–1998) and Clyde Cowan Jr. (1919–1974).
1931	Carl David Anderson (1905–1991)	Discovery of the positron, antiparticle for the electron. The “positron” was predicted by Paul Adrien Maurice Dirac (1902–1984) in 1929.
1932	Sir James Chadwick (1891–1974)	Discovery of the neutron. Student of Ernest Rutherford (1871–1937).
1934	Leo Szilard (1898–1964)	Recognition of nuclear decay chain reactions.
1934	Hideki Yukawa [湯川 秀樹], (1907–1981)	Introduction of mesons and the concept of antimatter.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1934	Ida Noddack (1896–1978)	Formal introduction of the concept of “fission”; however, not recognized by her peers at the time. The fission phenomenon was only recognized when announced by Enrico Fermi (1901–1954) later that year.
1934	Enrico Fermi (1901–1954)	Interaction of slow neutron with nuclei and the resulting decay into different elements, including aluminum and uranium.
1935	Arthur Dempster (1886–1950)	Discovery of the lighter uranium isotope: Uranium-235.
1936	Otto Hahn (1879–1968) and Lise Meitner (1878–1968)	Neutron collision of uranium-induced decay examination.
1937	Carl David Anderson (1905–1991), Seth Henry Neddermeyer (1907–1988), Jabez Curry Street (1906–1989), and Edward C. Stevenson (1937–)	Confirmation of the existence of the meson and muon. Subatomic particles are governed by quantum physics principles, and will exhibit a wave–particle duality. The quantum state energy vectors are represented in Hilbert space.
1938	Niels Henrik David Bohr (1885–1962) and John Archibald Wheeler (1911–2008)	Formal description of the nuclear fission process.
1939	Jerome M. B. Kellogg (1905–?)	Discovery of a finite quadruple moment for the deuteron, requiring a noncentral (tensor) nuclear force configuration.
1940	Otto Robert Frisch (1904–1979)	Development of the detonation mechanism for the first atomic bomb.
1940+	Julius Robert Oppenheimer (1904–1967)	Manhattan project: fission reaction. Prominent members: Arthur Compton (1892–1962); Enrico Fermi (1901–1954); Eugene Wigner (1902–1995), and dozens more.
1945	Edwin Mattison Mcmillan (1907–1999) next to Vladimir Iosifovich Veksler (1907–1966)	Independent introduction of the principle of the synchrotron. The synchrotron accelerator produces very high-energy particles, as in the Cosmotron, Brookhaven National Laboratory, USA, or Bevatron, Lawrence Berkeley National Laboratory, USA operating at 10 BeV.
1946		Introduction of the term “Lepton”, defining weak nuclear interaction particles; electrons and muons are hence considered leptons.
1947	George Dixon Rochester (1908–2001) and Clifford Charles Butler (1922–1999)	Discovery of the subatomic particle: the “kaon,” k-meson. Introduction of the “strangeness” concept for quarks, although the quark concept had not been introduced. In the elementary particle phenomenology the kaon is a bound state of an up- or down quark with a strange quark (anti-quark).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1947	Maria Goeppert-Mayer (Göppert) (1906–1972)	Theoretical concept development for the understanding of nuclear forces, based on a shell model, similar to the atomic electron model.
1947	William Webster Hansen (1909–1949)	Linear accelerator installation at Stanford University, California.
1950	Maria Goeppert-Mayer (Göppert) (1906–1972)	Introduction of the nuclear shell model for atomic nuclei.
ca. 1952	Ludwig von Helmholtz (1821–1894), Lyman Strong Spitzer, Jr. (1914–1997) and Ronald Richter (1909–1991) and Edward Teller (1908–2003)	Nuclear fusion investigation and start of experimentation. The process was in principle described by Hermann Ludwig Ferdinand von Helmholtz (1821–1894), but is continuously in action at the sun's surface.
1954	Chen-Ning Franklin Yang (1922–2004) and Robert Laurence Mills (1927–1999)	Introduction of “Gauge Theories.” These gauge theories will eventually form the basis for the “standard model.”
1955	Obninsk Nuclear Power Station, Russia	First nuclear power station for energy generation.
1956	Frederick Reines (1918–1998) and Clyde Lorrain Cowan, Jr. (1919–1974)	Experimental confirmation of the neutrino introduced in 1931 by Wolfgang Pauli (1900–1958).
1957	Julian Schwinger (1918–1994), Sidney Bludman (1927–), Sheldon Lee Glashow (1933–), and Hideki Yukawa (1907–1981)	Bosons provide the weak attraction. Initially conceived by Hideki Yukawa (1907–1981) in 1937. These heavy bosons are referred to as W^- and W^+ .
1958	Stanley Mandelstam (1928–2016)	Introduction of Mandelstam variables associated with the concept of “crossing symmetry,” defining numerical quantities that encode the energy, momentum, and scattering angles of particles in a deflection process described in a Lorentz-invariant fashion.
1958	Lev Davidovich Landau [Russian: Лёв Давидович Ландау] (1908–1968), Arkady Beynusovich Migdal [Russian: Аркадий Бейнусович Бенедиктович Мигдал] (1911–1991)	Theory of interacting electrons, specifically with respect to solids; condensed matter physics.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1961	Murray Gell-Mann (1929–)	Description of elementary particles, eight-fold way of defining “strangeness” for the quark. Formal introduction of the elementary particle “quark” concept, the building blocks for protons and neutrons. The “quark” name is based on an expression in the book <i>Finnegans Wake</i> by James Joyce.
1964	Charles Hard Townes (1915–2015), Nikolay Gennadiyevich Basov [Никола́й Генна́диевич Ба́сов] (1922–2001), and Aleksandr Mikhailovich Prokhorov [Алекса́ндр Миха́йлович Про́хоров] (1916–2002)	Quantum electronics.
1965	Oscar Wallace Greenberg (1932–), Moo-Young Han (1934–), and Yoichiro Nambu [南部陽一郎] (1921–)	Introduction of the concept of “color” change as designation and property for quarks.
1970	Sheldon Lee Glashow (1932–), John Iliopoulos (1940–), and Luciano Maiani (1941–)	Introduction of the charm quark.
1973	Hugh David Politzer (1949–), David Jonathan Gross (1941–), and Frank Anthony Wilczek (1951–)	Discovery associating the quark color theory of the strong interaction to a special property, referred to as “asymptotic freedom.” This “color” property is required to describe the data acquired over the prior period from 1968 to 1969 with respect to the substrate of the proton.
1974	Burton Richter (1931–) and Samuel Chao Chung Ting [Chinese: 丁肇中] (1936–)	Description of charm for the quark.
1975	Carlo Rubbia (1934–), Burton Richter (1931–), Frederick Reines (1918–1998), Jack Steinberger (1921–), Leon Lederman (1922–), Richard Taylor (1929–), Jerome Friedman (1930–), and Martin Perl (1927–2014)	Standard model of particle interaction. Interactions between leptons and quarks, interacting by means of bosons. Listing the contributing scientist that led to the discovery of the various elementary particles, respectively: W and Z boson; charm quark; neutrino; muon–neutrino; muon–neutrino, and b-quark; quarks (general); quarks (general); tau.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1975	Martin Lewis Perl (1927–2014)	Discovery of the tau lepton.
1977	Leon Max Ledderman (1922–)	Discovery of the “beauty” and “bottom” designation for quarks.
1978		Discovery of the “gluon” with the assistance of the PLUTO, the first electromagnetic superconductive solenoid located in Hamburg, Germany.
1983	Collider Detector at Fermilab	World’s first and at the time highest-energy particle accelerator, colliding antiprotons and protons propelled to center-of-mass energy reaching 2 TeV.
1995	Wolfgang Ketterle (1957–), Eric Allin Cornell (1961–), and Carl Edwin Wieman (1951–)	Experimental verification of Bose–Einstein condensation.
2012	François Baron Englert (1932–) and Peter Ware Higgs (1929–)	Higgs boson (126 GeV) discovery in the Large Hadron Collider at CERN, Geneva, Switzerland. The Large Hadron Collider construction started in 1998 and produces particle acceleration with respective energy levels for protons at up to 4 teraelectronvolts (0.64 microjoules), or lead nuclei: 2.76 TeV per nucleon or 574 TeV per nucleus. The proton energy level was increased to 6.5 TeV in 2015.

Imaging

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 410 BC	Mozi (ca. 470 BC–390 BC)	Chinese philosopher. Description of the use of a pin hole for the projection of an image on a wall of a darkened compartment (room); the initial concept of the camera obscura.
350 BC	Aristotle (384 BC–322 BC)	Documented recordings of a solar eclipse based on the principles of the camera obscura. His image formation was based on the projection of the sun through gaps between the leaves of a tree.
ca. 300 BC	Euclid of Alexandria (ca. 350 BC–280 BC)	Publication of the treatise on light: <i>Optics</i> (Ὀπτικά), describing the principles of the image formation for light traveling in straight lines, the camera obscura, next to general vision aspects.
1480	Leonardo da Vinci (1452–1519)	Experimentation with image formation using an ox eye from which he had scraped the retina, providing a lens with “screen” that forms an image. Additional experimentation with the principles of the camera obscura for image projection.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1560	1560: Bernardino de Sahagún (ca. 1499–ca. 1590), 1565: Nicolás Monardes (1493–1588), 1819: Edward Daniel Clarke (1769–1822), 1822: René Just Haüy (1743–1822), 1833: David Brewster (1781–1868), and 1933: Aleksander Jabłoński (1898–1980)	Fluorescence imaging and spectroscopy. The principles of fluorescence are captured by the Jablonski diagram.
1590–1608	Hans Jansen (father of Zacharias) and Zacharias Jansen (1580–1640) and later Hans Lippershey (1570–1619).	Introduction of the optical microscope.
1610	Galileo Galilei (1564–1642)	Improvements to the microscope design by introducing focusing capabilities.
1640	Antonie van Leeuwenhoek (1632–1723)	Refined microscope design. Beginning of microbiology and large-scale microscopic investigations.
1794	Lazzaro Spallanzani (1729–1799)	First documented outline of waves in spatial orientation, forming the foundation for modern ultrasonic imaging.
1816	René Théophile-Hyacinthe Laennec (1781–1826)	Introduction of the stethoscope.
1826	Jean-Daniel Colladon (1802–1893)	Use of ringing a church bell for underwater range finding. Rudimentary “ultrasound” principle.
1864	August Joseph Ignaz Toepler (1836–1912)	Schlieren imaging, refraction of light in a substance as a function of local density or local chemical concentration. Also referred to as “shadow imaging.”
1880	Francis Galton (1822–1911)	Construction of a device capable of generating sound waves of 40,000 Hz. Furthering the imaging capabilities with respect to ultrasound, initially attempted to mimic the observation techniques used by bats.
1880	Paul-Jacques Curie (1855–1941) and Pierre Curie (1859–1906)	Discovery of electric charges emerging on the surfaces of certain crystals, which are subjected to pressure or tension (shear or normal stress). This is referred to as the piezoelectric effect. Supporting technology for ultrasound imaging.
1895	Wilhelm Conrad Röntgen (1845–1923)	Primary X-ray imaging feasibility.
1900	Max Karl Ernst Ludwig Planck (1858–1947)	(Planck’s) radiation law, describing the concept of black body radiation used in thermographic imaging.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1915	Paul Langevin (1872–1946)	Introduction of “hydrophone” for underwater detection of obstacles.
1922	Erwin Rudolf Josef Alexander Schrödinger (1887–1961) and Hermann Klaus Hugo Weyl (1885–1955)	Introduction of the quantum mechanical principles, which formed the basis for several imaging techniques.
1924	Louis-Victor-Pierre-Raymond, 7th duc de Broglie (1892–1987)	Introduction of the wave phenomenon with respect to all object in motion. Matter wave, propagating with the de Broglie wavelength.
1926	Hans Busch (1884–1973); Leó Szilárd (1898–1964)	Electron microscopy, transmission (TEM), respectively, reflection/scanning (SEM). The resolution principle is based on the wave motion of the moving electron, propagating with the de Broglie wavelength, as a function of the applied energy.
1927	Wolfgang Ernst Pauli (1900–1958), Ralph Kronig (1904–1995), George Eugene Uhlenbeck (1900–1988), Samuel Abraham Goudsmit (1902–1978), and Paul Adrien Maurice Dirac (1902–1984)	Introduction of the electron spin concept and a broad range of relativistic quantum mechanical principles. This formed the foundation for the development of the NMR imaging system: nuclear magnetic resonance (MRI).
1928	Sir Chandrasekhara Venkata Raman (1888–1970)	Raman spectroscopy.
1937	Karl Dussik (1908–1968)	First recorded event of medical use of ultrasonic imaging.
1946	Felix Bloch (1905–1983) and Edward Mills Purcell (1912–1997)	Fundamental concept introduction providing the mechanism of action for magnetic resonance imaging (MRI).
1951	Erwin Wilhelm Müller (1911–1977)	(Scanning) Helium ion microscopy. The basic principles are very similar to the SEM. The He ion microscope uses both the atomic and molecular interaction of the incident helium ions for “density imaging” on the observed target as well as Rutherford backscattering spectroscopy to derive material properties. In comparison to the SEM, He ion microscope produces 3 to 9 secondary electrons, versus only one for SEM. The work of Erwin Müller on the field ion microscope provided the operational foundation. Erwin Müller first introduced the field emission electron microscope in 1951. The first operational He ion microscope was produced in the first decade of the twenty-first century.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1951+	Douglas Howry (1920–1969) and Joseph H. Holmes (1902–1982)	Pioneering two-dimensional B-mode ultrasound imaging.
1957	Marvin Lee Minsky (1927–)	Confocal microscopy.
1957	Herman P. Schwan (1915–2005)	Bioelectric impedance tomography (electric impedance tomography) and dielectric spectroscopy. Imaging mechanism based on the Maxwell–Wagner effect (polarization); based on the work of James Clerk Maxwell (1831–1879) and Karl Willy Wagner (1883–1953) in the early part of the twentieth century. The Maxwell–Wagner polarization mechanism, which reveals very large effective electric permittivity on scales larger than molecular size. The polarization can be artificially induced and has an associated specific (characteristic) relaxation time. Note: Herman Schwan (Schwann) is sometimes referred to as the “founding father of biomedical engineering.” One of the examples of bioelectric impedance tomography outside the use on humans is in the food industry. Impedance tomography is also used in geological investigation; geophysics application.
1957+	David Edmund Kuhl (1929–), Luke Chapman (), and Roy Edwards ()	Positron emission tomography (PET).
1971	Sir Godfrey Newbold Hounsfield (1919–2004) and respectively Allan MacLeod Cormack (1924–1998)	Computed tomography.
1973	Paul Christian Lauterbur (1929–2007)	First operational MRI machine.
1981	Gerd Binnig (1947–) and Heinrich Rohrer (1933–2013)	Design of the scanning tunneling microscope (STM).
1986	Gerd Binnig (1947–), Heinrich Rohrer (1933–), Calvin Quate (1923–), and Christoph Gerber (1942–)	Initial concepts for the atomic force microscope (AFM) were introduced.
1989	Paul K. Hansma (1946–), B. Drake (), O. Marti (), S.A. Gould (), and C.B. Prater ()	Scanning ion-conducting microscope. Imaging technique with close correlation to superconductivity.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1990	Naohiro Tanno () and various groups with refinements by the MIT group consisting of David Huang (), James G. Fujimoto (), Carmen A. Puliafito (), and others.	Optical coherence tomography.

Instrumentation

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
6000 BC–2000 BC	Stone Age	Mechanical labor and tool fabrication.		Coherence tomography
				MRI
ca. 6000 BC		First recorded use of floatation devices: boats. This illustrated the Archimedes principle (Archimedes [287 BC–212 BC]), but no documented descriptions on the floatation principles from those days.		PET
				Ultrasound
ca. 4000 BC	Eastern Europe	First recorded drawing of craft with rudimentary wheels.		X-ray
				mass spectrometer
4000 BC	Mesopotamia and Egypt	Documented recording of the construction of shelter, abandoning the nomadic structure.		Geiger counter
				Geiger–Muller
ca. 3500 BC		First documented installation of sewer systems, primarily run-off.		
ca. 3300 BC	Egypt	Drawings of sailboats.		
ca. 3000 BC		Traceable use of a potter's wheel used for the construction of crockery.		
3300 BC–1000 BC	Bronze Age	Smelting and forging of soft metals using low heat: copper, tin, gold. This age also introduces the written documentation.		
2700 BC–2500 BC	Egypt	Construction of pyramids, requiring advanced mechanical engineering efforts and architectural design (civil engineering).		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
ca. 1000 BC	Qanat aqueduct; Perzia	Water supply over a length greater than 71 km, and potential relation with sewer as a secondary use for liquid transport as part of the civil engineering efforts.		
1000 BC–700 AD	Iron Age	Higher heat requirements and more detailed tool manufacturing, introducing scientific and engineering challenges. Historical tracking of processes and developments and philosophies. Introduction of complicated mechanisms and requiring detailed analytical thinking.		
ca. 600 BC	Thales of Miletus (ca. 624 BC–ca. 546 BC; known as Thales: Θαλῆς)	Introduction of standardized and validated metrology.		
ca. 360 BC	Plato (427 BC–347 BC)	Rudimentary astronomy record keeping.		
40 BC	Marcus Vitruvius Pollio [Vitruvius] (ca. 80 BC–10 BC)	Roman engineering architect and civil engineer. Vituvius served under Gaius Julius Caesar (100 BC–44 BC). In the army position he was also charged with the care of the infirmed, where he used early biomedical engineering approaches for novel diagnosis and treatment.		
62	Hero of Alexandria [ῥων ὁ Ἀλεξανδρεύς] (10–70)	Mathematician, physicist, and mechanical engineer who also taught pneumatics. A set of two books <i>The Pneumatica</i> describes mechanical devices worked by air, steam, or water pressure. Also known as Heron of Alexandria. He invented a steam-powered engine called the “Æolipile.”		
120	Claudius Ptolemy {Ptolemaeus} [Πτολεμαῖος] (90–168)	Geographic recordings of a significant part of the Islamic and western world (i.e., Roman and Persian Empire), living in Egypt, as a Roman with Greek education. His cartography extended all the way out, including parts of China (discovered in fifteenth century). He specifically developed arithmetical techniques for calculating astronomical phenomena, under the teachings of Babylonian astronomers. Also known as بطليموس (Batlaymus; Arabic)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
644		Wind-powered devices developed by the Persians.		
1010	Eilmer of Malmesbury, eleventh century Benedictine monk	First documented successful flight, performed with a wooden frame lined with parchment, traveling approximately 200 m in free-fall from a 18-m elevation.		
1500	Leonardo da Vinci (1452–1519)	The preverbal “Renaissance man”, involved in all aspects of cultural evolution, science, engineering, politics and art.		
1503	Gregor Reisch (1467–1525)	Detailed outline of the state-of-the-art science and engineering knowledge to date, including human anatomical drawings in the publication: <i>Margarita Philosophica</i> . The total works of Gregor Reisch form a series of twelve (12) books compiling an encyclopedia describing topics ranging from Latin grammar, to dialectics, rhetoric, arithmetic, music, geometry, astronomy, physics, natural history, physiology, psychology, and ethics.		
1512	Gregorius Reisch (1467–1525)	Introduction of the concept of the theodolite, used for topography and geographic location determination.		
1590	Francis Bacon, 1st Viscount of St. Alban (1561–1626)	Regulate the general scientific methodology.		
ca. 1600	William Gilbert (1544–1603)	Experimentalist. Description of magnetism, in his work: <i>De magnete, magnetisque corporibus, et de magno magnete tellure</i> . The compass had been in use since 206 BC (Chinese Han Dynasty: 206 BC–220 AD; maybe even earlier, during the Qin Dynasty: 221 BC–207 BC), in the European and Persian area since the thirteenth century.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
ca. 1600	Galileo Galilei (1564–1642)	Major contributor to the scientific revolution and the (re)introduction of analytical thinking in science, engineering, and general thought processes. Galileo Galilei was remanded under house arrest by the Roman Inquisition for his views and teachings where he died after 9 years. This was the trailing end of the Renaissance period.		
1558	Giambattista della Porta (1535–1615)	Incorporation of a lens in the opening of a camera obscura—improved the image formation capabilities.	New	
~1590	Zacharius Janssen (1585–1632)	Constructed a compound microscope with a converging objective lens and a diverging eye lens.		
1604	Johannes Kepler (1571–1630)	In his book <i>Ad Vitellionem Paralipomena</i> , Kepler suggested that the intensity of light from a point source varies inversely with the square of the distance from the source, that light can be propagated over an unlimited distance, and that the speed of propagation is infinite. He explained vision as a consequence of the formation of an image on the retina by the lens in the eye and correctly described the causes of long-sightedness and short-sightedness. Conforming the heliocentric model calculated by Nicolaus Copernicus (1473–1543).		
1604	Johannes Kepler (1571–1630)	Formal introduction of the term “camera obscura.”	new	
1608	Hans Lippershey (1570–1619)	Constructed a telescope with a converging objective lens and a diverging eye lens.		
1609	Galileo Galilei (1564–1642)	Construction of his own version of the telescope design of Hans Lippershey (1570–1619) and used it for astronomical observations. Galileo documented several astronomical discoveries including the four (4) moons of Jupiter.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1611	Giovanni Demisiani (?–1614)	Introduced the term “telescope” for his device with three times (3X) magnification.	new	
1611	Johannes Kepler (1571–1630)	In his book <i>Dioptrice</i> an explanation is provided for the principles involved in the convergent/divergent lens telescopes and microscopes. The telescope could be constructed using a converging objective and a converging ocular lens. The lens assembly description resembles that for the telephoto lens. Kepler also discovered total internal reflection, but could not effectively describe the optical and geometric relationship between the angle of incidence and the angle of refraction.		
1614	René Descartes (1596–1650)	Introduction to vortex motion. Introduction of the concept of general corpuscular motion, extending from small (maybe referring to the undefined atom), to planetary orbits. Descartes also made an illustration of the earth’s magnetic field configuration in 1644, in his model the moon and celestial objects participated in the formation of the path of the magnetic field lines. Based on the limited experimental observations available in his time the premise was still not bad.		
~1618	Christopher Scheiner (1573–1650)	Constructed a telescope of the type suggested by Johannes Kepler (1571–1630) with converging objective lens system. This type of telescope become the standard “astronomical telescope.”		
1632	Evangelista Torricelli (1608–1647)	Introduction of the barometer; essential in weather prediction; meteorology.		
1650	Blaise Pascal (1623–1662)	Pascal’s law, pressure in a container applies an equal force on all surface of the enclosure		
ca. 1655	Christiaan Huygens (1629–1695)	Invention of a clockwork mechanism capable of timekeeping while at sea in order to allow for accurate geographical measurements.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1660	Robert Boyle (1627–1691)	Gas laws, definition of the behavior of gases. Boyle mentioned the compression of gas as a potential “shock absorber,” acting similar to a spring.		
1673	Christiaan Huygens (1629–1695)	Construction of a “combustion engine” powered by gun powder. Huygens introduced several concepts of mechanical engineering and described the mechanism of shock waves. Christiaan Huygens is most known for his lens manufacturing and optical design of telescopes. The mathematical efforts of Christiaan Huygens in probability theory were far advanced and he collaborated with the mathematician Pierre de Fermat (1601–1665) from France.		
1679	Denis Papin (1647–ca. 1712)	Pressure and thermodynamic and mechanical impacts.		
1680	Robert Hooke (1635–1703)	Force applied by a compressed spring.		
ca. 1687	Sir Isaac Newton (1643–1727)	Sir Isaac Newton introduced several laws of motion. The publication of the <i>Philosophiæ Naturalis Principia Mathematica</i> provides detailed definitions regarding ballistic motion, circular motion (centripetal force), laws of action-reaction, gravitational acceleration, inertia and force with respect to acceleration. Introduction of the three laws of motion.		
1698	Thomas Savery (1650–1715)	Construction of the basic steam engine; using information obtained by Denis Papin (1647–c. 1712).		
1705	Edmond Halley (1656–1742)	Discovery of, and mathematical description of the trajectory for “Halley’s comet”.		
1712	Thomas Newcomen (1664–1729)	Construction of a “atmospheric” steam engine.		
1714	Brook Taylor (1685–1731)	Fundamental frequency of vibration; string. Additional work on pure mathematics: Taylor series.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1727	Leonard Euler (1707–1783)	Introduction of the concept of the elastic modulus, experimentally verified by Giordano Riccati (1709–1790) in 1782 and mathematically introduced by Thomas Young (1773–1829) in 1807, now known as Young's modulus.		
1729/1733	Chester Moore Hall (1703–1771)	Construction of achromatic compound lenses using components consisting of glasses with different refractive indices. Construction of first refracting telescope that has chromatic aberration correction.		
1732	Anders Celsius (1701–1744)	Thermometer scale calibration based on pure water phases.		
1733	Daniel Bernoulli (1700–1782)	Acoustics, mechanical vibrations, and fluid dynamic principles introduced. Definition of the fundamental frequency and higher harmonics, with supporting elaborate mathematical analysis (solutions to differential equations).		
1735	Daniel Gabriel Fahrenheit (1686–1736)	Temperature scale in Fahrenheit based on body temperature and saltwater phases		
1757–1769	James Watt (1736–1819)	Modern steam engine design and operation with theoretical description of operation.		
1769	Nicolas-Joseph Cugnot (1725–1804)	First operational steam powered automobile, the predecessor to the internal combustion automobile.		
1783	Joseph-Michel Montgolfier (1740–1810) and Jacques-Étienne Montgolfier (1745–1799)	Hot-air balloon; buoyancy.		
1785	Jacques Alexandre César Charles (1746–1823)	Charles's law, expansion of gases.		
1800	Count Alessandro Giuseppe Antonio Anastasio Volta (1745–1827)	Introduction of the battery.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1802	Joseph Louis Gay-Lussac (1778–1850)	Ideal gas law; building on the work by Robert Boyle (1627–1691), more than a century earlier.		
1807	Thomas Young (1773–1829)	Formal introduction of the Young's Modulus for elastic deformation, tying strain to stress, based on the work by Leonard Euler (1707–1783).		
1821	Michael Faraday (1791–1867)	Discovery of electromagnetic rotation, leading to his law on electromagnetic induction in 1831. Meanwhile, in 1923 Michael Faraday experimentally verified the concept of refrigeration, introduced based on the work of John Dalton (1766–1844) in 1802 and William Cullen (1710–1790) in 1756.		
1823	Nicéphore Niépce (1765–1833) and Louis Jacques-Mandé Daguerre (1787–1851)	Introduction of Photography, using the earlier efforts of Albertus Magnus (1193–1280) with his discovery of silver nitrate, and Georg Fabricius (1516–71) who discovered silver chloride.		
1824	Nicolas Léonard Sadi Carnot (1796–1832)	Refrigerator for general public.		
1826	Jean-Daniel Colladon (1802–1893)	Use of ringing a church-bell for underwater range-finding. Rudimentary “ultrasound” principle.		
1827	Benoît Fourneyron (1802–1867)	First water turbine.		
1831	Michael Faraday (1791–1867) and Joseph Henry (1797–1878)	Law of induction, leading to the development of the electric generator.		
1848	William Thomson, 1st Baron Kelvin (i.e., Lord Kelvin) (1824–1907)	Absolute temperature scale: Kelvin.		
1851	Jean Bernard Léon Foucault (1819–1868)	Foucault pendulum, illustrating the impact of the earth's rotation on motion.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1852	James Prescott Joule (1818–1889) and William Thomson, 1st Baron Kelvin {Lord Kelvin} (1824–1907)	Joule–Thomson effect: rapidly expanding gas leads to a reduction in the temperature of the gas, even offering the potential for a phase change to solid, or liquid. Sometimes also found as the Joule–Kelvin effect		
1854	Robert Wilhelm Eberhard Bunsen (1811–1899)	Bunsen burner.		
1861	William Froude (1810–1879)	Applications to ship design, reducing the roll of a ship by means of a keel. The hydrodynamic behavior of the hull of a ship could be gauged based on the Froude number, derived from a set of experimental obtained data points.		
1880	Francis Galton (1822–1911)	Construction of a device capable of generating sound waves of 40,000 Hz. Furthering the imaging capabilities with respect to ultrasound, initially attempted to mimic the observation techniques used by bats.		
1887	Heinrich Rudolf Hertz (1857–1894)	Radar development. Detection of electromagnetic radiation (radio waves). Heinrich Hertz also discovered that certain metal plates will generate electricity when exposed to light: photo-electric effect.		
1895	Wilhelm Conrad Röntgen (1845–1923)	Primary X-ray imaging feasibility.		
1897	Joseph John Thomson (1856–1940)	Discovery of the electron; using William Crookes's vacuum tube.		
1897	Guglielmo Marconi, 1st Marquis of Marconi (1874–1937)	Introduction of wireless communications and radio.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1898	Antoine Henri Becquerel (1852–1908)	Introduction of units for radioactivity radiation. Collaborator with Many (Marie) Skłodowska Curie (1867–1934). Henri Becquerel, Marie Curie, and Pierre Curie shared the Nobel Prize in Physics for their radioactivity discoveries in 1903.		
1900	Ferdinand Adolf Heinrich August Graf von Zeppelin (1838–1917)	Successful dirigible, gas-filled air floatation device with propulsion.		
1904	John Ambrose Fleming (1849–1945)	Application of the Edison effect to make the first thermionic valve (“radio” tube).		
1906	Lee De Forest (1873–1961)	Construction of the first audion (triode) by introducing a grid into a Fleming valve, tube electronics.		
1907–1912	Joseph John Thomson (1856–1940)	Devised methods of positive ray analysis. These processes formed the beginning of mass spectroscopy.		
1909	Guglielmo Marconi (1874–1937) and Carl Ferdinand Braun (1850–1918)	Were jointly awarded the Nobel Prize in Physics—the former for combining the basic knowledge about Hertzian waves to produce wireless telegraphy, and the latter for the study, production, and use of electrical oscillators. Braun also developed the Braun tube, called the “cathode-ray” tube in the United States.		
1911	Charles Thomson Bees Wilson (1869–1959)	Construction of the first expansion cloud chamber, used for particle research. This is one of the most important device in nuclear physics. Charles Wilson was awarded the Nobel Prize in Physics jointly with Arthur Holly Compton (1892–1962) in 1927.		
1915	Paul Langevin (1872–1946)	Introduction of “hydrophone” for underwater detection of obstacles.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1918	Paul Scherrer (1890–1969)	X-ray diffraction, crystal structure. Nuclear energy development. Established the CERN institute in Switzerland as one of the founders. Directed the construction of the first cyclotron in 1940.		
1925	Walter M. Elsasser (1904–1991)	Predicted from de Broglie theory illustrating how electrons could be diffracted by crystals.		
1926	Mark Cowley Lidwell (1878–1969) and Edgar Harold Booth (1893–1963)	Rudimentary, but effective, external cardiac pacemaker design.		
1926	Hans Busch (1884–1973); Leó Szilárd (1898–1964)	Electron microscopy, transmission (TEM), respectively, reflection/scanning (SEM). The resolution principle is based on the wave motion of the moving electron, propagating with the de Broglie wavelength, as a function of the applied energy.		
1930	Richard Buckminster Fuller (1895–1983)	Mechanical engineering and engineering architecture, as well as chemistry; Bucky-ball, multipoint connections in both chemical structures and mechanical structures.		
1931	Georges Jean Marie Darrieus (1888–1979)	Introduction of the wind turbine.		
1932	Ernest Orlando Lawrence (1901–1958) and Milton Stanley Livingston (1905–1986)	Construction of the first cyclotron. Ernest Lawrence received the Nobel Prize in Physics in 1939.		
1933	Patrick M. S. Blackett (1897–1974) and Guiseppe P. S. Occhialini (1907–1993)	Obtained the first cloud chamber photographs of electron–positron pair production.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1937	Karl Dussik (1908–1968)	First recorded event of medical use of ultrasonic imaging.		
1940	Louis Leprince-Ringuet (1901–2000)	Obtained the first cloud chamber photograph of a collision between a meson and an electron, from which the mass of the meson could be derived.		
1940	Donald William Kerst (1911–1993)	Made the first betatron, an induction type accelerator.		
1940+	Julius Robert Oppenheimer (1904–1967)	Manhattan project: fission reaction. Prominent members: Arthur Compton (1892–1962), Enrico Fermi (1901–1954), Eugene Wigner (1902–1995), and dozens more. One notable result is the creation of nuclear power plants.		
1937–1959	Chester Floyd Carlson (1906–1968)	Photocopy machine, patented in 1942. The first photocopier was offered for sale by the Haloid company in 1959, later renamed Xerox.		
1947	Hartmut Paul Kallmann (1896–1978), next to John Wesley Coltman (1915–) next to Fitz-Hugh Ball Marshall (1912–)	Developed scintillation counters.		
1948	Dennis Gabor (1900–1979)	Description of the principles of wavefront reconstruction, evolving into holography.	c	
1950	John Alexander Hopps, (1919–1998)	Introduction of the “portable” (45 kg) cardiac pacemaker, based on the earlier work by Mark Lidwell (1878–1969) and Edgar Harold Booth (1893–1963) in 1926. This led, with the development of microprocessors, to the first implantable pacemaker in 1958 by William Chardack (1919–2011) and Wilson Greatbatch (1919–2011).		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1951	Erwin Wilhelm Müller (1911–1977)	(Scanning) Helium ion microscopy. The basic principles are very similar to the SEM. The He ion microscope uses both the atomic and molecular interaction of the incident helium ions for “density imaging” on the observed target as well as Rutherford backscattering spectroscopy to derive material properties. In comparison to the SEM the He ion microscope produces 3 to 9 secondary electrons, versus only one for SEM. The work of Erwin Müller on the field ion microscope provided the operational foundation. Erwin Müller first introduced the field emission electron microscope in 1951. The first operational He ion microscope was produced in the first decade of the twenty-first century.		
1951+	Douglas Howry (1920–1969) and Joseph H. Holmes (1902–1982)	Pioneering two dimensional B-mode ultrasound imaging.		
1952		Brookhaven National laboratory was the first to achieve the acceleration of particles to the giga-electron-volt energy range: 2.3-Gev protons.		
ca. 1952	Ludwig von Helmholtz (1821–1894), Lyman Strong Spitzer, Jr. (1914–1997) and Ronald Richter (1909–1991) and Edward Teller (1908–2003)	Nuclear fusion investigation and start of experimentation. The process was in principle described by Hermann Ludwig Ferdinand von Helmholtz (1821–1894), but is continuously in action on the sun’s surface.		
1952	Donald Arthur Glaser (1926–2013)	Made the first bubble chamber. He was awarded the Nobel Prize in Physics in 1960. The first large-scale, terrestrial thermonuclear reaction was produced when a “hydrogen fusion device” was tested at Einewetok atoll on November 1.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1955	Obninsk Nuclear Power Station, Russia	First nuclear power station for energy generation.		
1956	Paul Winchell {Wilchinsky} (1922–2005)	Artificial heart (Jarvik 7).		
1957	USSR: Soviet Russia	Sputnik-1 [Russian: “Спúтник-1”]; first satellite.		
1957	Marvin Lee Minsky (1927–2016)	Confocal microscopy.		
1957	Herman P. Schwan (1915–2005)	Bioelectric impedance tomography (electric impedance tomography) and dielectric spectroscopy. Imaging mechanism based on the Maxwell–Wagner effect (polarization); based on the work of James Clerk Maxwell (1831–1879) and Karl Willy Wagner (1883–1953) in the early part of the twentieth century. The Maxwell–Wagner polarization mechanism, which reveals very large effective electric permittivity on scales larger than molecular size. The polarization can be artificially induced and has an associated specific (characteristic) relaxation time. <i>Note:</i> Herman Schwan (Schwann) is sometimes referred to as the “founding father of biomedical engineering.” One of the examples of bioelectric impedance tomography outside the use on humans is in the food industry. Impedance tomography is also used in geological investigation; geophysics application.		
1957+	David Edmund Kuhl (1929–), Luke Chapman (?), and Roy Edwards (?)	Positron emission tomography (PET).		
1971	Sir Godfrey Newbold Hounsfield (1919–2004) and respectively Allan MacLeod Cormack (1924–1998)	Computed tomography.		

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
1973	Paul Christian Lauterbur (1929–2007)	First operational MRI machine.		
1981	Gerd Binnig (1947–), Heinrich Rohrer (1933–)	Design of the scanning tunneling microscope (STM).		
1986	Gerd Binnig (1947), Heinrich Rohrer (1933–), Calvin Quate (1923–), and Christoph Gerber (1942–)	Initial concepts for the atomic force microscope (AFM) were introduced.		
1989	Paul K. Hansma (1946–), B. Drake (?), O. Marti (?), S.A. Gould (?), and C.B. Prater (?)	Scanning ion-conducting microscope. Imaging technique with close correlation to superconductivity.		
1990	Naohiro Tanno (?) and various groups with refinements by the MIT group consisting of David Huang (?), James G. Fujimoto (?), Carmen A. Puliafito (?), and others.	Optical coherence tomography (OCT).		
1961	Yuri Alekseyevich Gagarin [Russian: Юрий Алексеевич] (1934–1968); USSR: Soviet Russia	First space travel: Vostok spacecraft.		
1983	Collider Detector at Fermilab	World's first and at the time highest-energy particle accelerator, colliding antiprotons and protons propelled to center-of-mass energy reaching 2 TeV.		
2008	CERN, Switzerland	Large Hadron Collider, beginning of operations. To date no evidence supporting string theory or supersymmetry has been collected.		

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES		
2012	François Baron Englert (1932–) and Peter Ware Higgs (1929–)	Higgs boson (126 GeV) discovery in the Large Hadron Collider at CERN, Geneva, Switzerland.		

Material

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
6000 BC–2000 BC	Stone Age	Mechanical labor and tool fabrication
3300 BC–1000 BC	Bronze Age	Smelting and forging of soft metals using low heat: copper, tin, gold. This age also introduces the written documentation.
1000 BC–700 AD	Iron Age	Higher heat requirements and more detailed tool manufacturing, introducing scientific and engineering challenges. Historical tracking of processes and developments and philosophies. Introduction of complicated mechanisms and requiring detailed analytical thinking.
27 BC	Syria	Creation of glass.
400+	Italy	Lycurgus Cup, made with dichroic glass, consisting of early form nanoparticles. The cup shows a different color depending on whether illuminated from within or externally.
600	China	First documented production of ceramics.
1603	Sir Hugh Platt (1522–1608)	Hardening of metal.
1688	France	Construction of plate glass.
1774	Antoine Lavoisier (1743–1794)	Discovery of oxygen; and the chemical process of oxidation.
1782	Josiah Wedgwood (1730–1795)	Mass production of ceramic artifacts.
1811	Lorenzo Romano Amedeo Carlo Avogadro di Quaregna e di Cerreto, Count of Quaregna and Cerreto (1776–1856)	Molecular arrangements; molecular quantity in a mole of substance. Avogadro's law.
1821	Pierre Berthier (1782–1861)	Identification of the corrosion resistance properties for iron–chromium alloys; leading to stainless steel.
1836	Ignace Dubus-Bonnel ()	Introduction of a rudimentary form of fiberglass.
1839	William Hallows Miller (1801–1880)	Miller indices for lattice configuration, with specific applications to Bravais lattice structures.
1850	Auguste Bravais (1811–1863)	Uncovered lattice structure: Bravais lattice.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1855	Georges Audemars ()	Discovery of the process to produce rayon (cellulose nitrate); sometimes referred to as “artificial silk.”
1856	Sir Henry Bessemer (1813–1898)	Carbon steel.
1857	Michael Faraday (1791–1867)	Description of the unique optical properties for nanoparticles.
1874	Jacobus Henricus van't Hoff (1852–1911)	Introduction into the field of polymers.
1886	Friedrich Carl Zinoffsky (1830–??)	Determination of the polymer hemoglobin with molecular weight 16,700, following the work of Felix Hoppe-Seyler (1825–1895).
1887	Thomas Edison (1847–1931)	Advance ceramics processing technology.
1888	Wilhelm Roux (1850–1924)	Preliminary efforts leading to stem-cell research.
1901	Thomas Hunt Morgan (1866–1945)	Introduction of regenerative medicine, transplant research.
1902	Robert Williams Wood (1868–1955)	Surface plasmon resonance.
1906	Dmitri Ivanovich Mendeleev (1834–1907)	Periodic Table of Elements.
1908	William Henry Bragg (1862–1942) and William Lawrence Bragg (1890–1971)	Bragg diffraction law for crystalline lattice structures irradiated by X-ray radiation.
1908	Gustav Mie (1869–1957)	Scattering form nanoparticles, wavelength smaller than the scatter object size; Mie scatter.
1911	Heike Kamerlingh Onnes (1853–1926)	Discovery of superconductivity (metals).
1913	Niels Henrik David Bohr (1885–1962)	Bohr atomic model.
1916	Robert Andrews Millikan (1868–1953)	Experimentally verified Einstein's photoelectric equation.
1916	Peter Joseph Wilhelm Debye (Usa, 1884–1966), Paul Scherrer (B. 1890), next to Albert Wallace Hull (1880–1966)	Obtained the first experimental X-ray powder diffraction patterns.
1925	Wolfgang Ernst Pauli (1900–1958)	Pauli exclusion principle for atomic energy levels.
1929	Otto Stern (1888)	Obtained crystal diffraction of a beam of helium atoms.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1929	Wallace Hume Carothers (1896 – 1937)	Nylon discovered at Du Pont®.
1930	E. J. Williams () and William Lawrence Bragg (1890–1971)	Introduction of solid-state physics.
1931	Carl David Anderson (1905–1991)	Discovery of the positron, anti-particle for the electron. The “positron” was predicted by Paul Adrien Maurice Dirac (1902–1984) in 1929.
1934	Hideki Yukawa [湯川 秀樹], (1907–1981)	Introduction of mesons and the concept of antimatter.
1945	Dorothy Mary Hodgkin (1910–1994)	Protein crystallography, X-ray diffraction studies.
1947	George Dixon Rochester (1908–2001) and Clifford Charles Butler (1922–1999)	Introduction of the “strangeness” concept for quarks.
1953	Karl Ziegler (1898–1973)	Revolutionarized the process of polymerization, supporting mass production.
1958	Lev Davidovich Landau [Russian: Лёв Давидович Ландау] (1908–1968), Arkady Beynusovich Migdal [Russian: Аркадий Бейнусович (Бенедиктович) Мигдаль] (1911–1991)	Theory of interacting electrons, specifically with respect to solids; condensed matter physics.
1960		Introduction of the fiber-optic.
1961	James Edgar Till (1931–) and Ernest Armstrong McCulloch (1926–2011)	Stem cell research and forerunner of tissue engineering and regenerative medicine.
1965		Commercial development of the photovoltaic cell.
1965	Pierre-Gilles de Gennes (1932–2007)	Liquid crystal functionality.
1970	Sheldon Lee Glashow (1932–), John Iliopoulos (1940–), and Luciano Maiani (1941–)	Introduction of the charm quark.
1972	Stephen Hawking (1942–), Jacob Bekenstein (1947–2015)	Thermodynamics of black holes.
1974	Burton Richter (1931–) and Samuel Chao Chung Ting [Chinese: 丁肇中] (1936–)	Description of charm for the quark.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1975	Richard P. Blakemore ()	Magnetotactic bacteria.
1975	Claes-Göran Granqvist (1946–) and Robert A. Buhrman ()	Introduction of the concept and production of the first nanoparticles.
1975	Martin Lewis Perl (1927–2014)	Discovery of the tau lepton.
1977	Leon Max Ledderman (1922–)	Discovery of the “beauty” and “bottom” designation for quarks.
1978		Discovery of the “gluon” with the assistance of the PLUTO, the first electromagnetic superconductive solenoid located in Hamburg, Germany.
1980	Klaus von Klitzing (1943–)	Quantum Hall effect.
1987		Discovery of superconductivity in ceramic oxide, operating at higher temperature than metallic superconductors.
1991	Sumio Iijima [飯島 澄男] (1939–)	Discovery of carbon nanotube.
1995	Wolfgang Ketterle (1957–), Eric Allin Cornell (1961–), and Carl Edwin Wieman (1951–)	Experimental verification of Bose–Einstein condensation.
2012	François Baron Englert (1932–) and Peter Ware Higgs (1929–)	Higgs boson (126 GeV) discovery in the Large Hadron Collider at CERN, Geneva, Switzerland. The Large Hadron Collider construction started in 1998 and produces particle acceleration with respective energy levels for protons at up to 4 teraelectronvolts (0.64 microjoules), or lead nuclei: 2.76 TeV per nucleon or 574 TeV per nucleus. The proton energy level was increased to 6.5 TeV in 2015.

Mechanics

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 6000 BC	Egypt	First recorded drawings of rudimentary watercrafts.
ca 4000 BC	Eastern Europe	First recorded drawing of craft with rudimentary wheels.
4000 BC	Mesopotamia and Egypt	Documented recording of the construction of shelter, abandoning the nomadic structure.
ca. 3500 BC		First documented installation of sewer systems, primarily run-off.
ca. 3300 BC	Egypt	Drawings of sailboats.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
2700 BC–2500 BC	Egypt	Construction of pyramids, requiring advanced mechanical engineering efforts and architectural design (civil engineering).
ca. 1000 BC	Qanat aqueduct; Perzia	Water supply over a length greater than 71 km, and potential relation with sewer as a secondary use for liquid transport as part of the civil engineering efforts.
ca. 600 BC	Thales of Miletus (ca. 624 BC–ca. 546 BC; known as Thales: Θαλῆς)	Description of the “nature of objects.” Thales believed that objects are alive; part of the stream of thought by the “Hylozoists.”
430 BC	Socrates (470 BC–399 BC)	School of analytical thinking. Introduction to the base principles of what is currently considered classical mechanics.
350 BC	Aristotle (384 BC–322 BC)	Founder of the Lyceum school of analytical thinking in Macedonia. Aristotle described the initial concepts of physics, motion, time as well as astronomy concepts. Aristotle proposed the concept of an external force (acting during flight) perpetuating the projectile motion of a ballistic object, however incorrect, apart from gravity forcing the object down.
ca. 250 BC	Archimedes (287 BC–212 BC)	Hand operated corkscrew water pump. The philosophies of Archimedes shaped the development process of modern engineering.
ca. 220 BC	China	Civil engineering effort of the architectural and mechanical design and construction of the Great Wall, Ming Dynasty.
40 BC	Marcus Vitruvius Pollio [Vitruvius] (ca. 80 BC–10 BC)	First recorded use and description of the mechanism-of-action of a steam-operated engine to perform work: Æolipile; described in <i>De Architectura</i> .
62	Hero of Alexandria [ῥων ὁ Ἀλεξανδρεὺς] (10–70)	Second recorded use of steam to provide power to a machine; Æolipile.
650		First recorded use of wind mills and wind energy in the Persian Empire.
800	Persia, the Netherlands; detailed scientific documentation by Simon Stevin (1548–1620)	Wind energy used to pump water, windmill water pump: wind pump. Other use of the windmill was in manufacturing, for example, papermaking, cloth fabrication, wheat processing, and (much) later for the generation of electricity. Jan Adriaanszoon Leeghwater [Leechwater] (1575–1650); draining a significant area of land north from Amsterdam to make it habitable in 1612 (son of carpenter Adriaan Symonszoon [–1618]).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
900–1200	Mexico, central America	Construction of temples, which apparently have a close correlation to astronomical observations. Civil engineering.
1206	Al-Jazari (1136–1206) [Turkey]; Badi'al-Zaman Abū al-'Izz ibn Ismā'il ibn al-Razāz al-Jazarī (Arab: <i>بْنُ الْعِزِّ أَبُو الزَّمَانِ بَدِيعُ الْجَزَرِيِّ الرَّزَازُ بْنُ إِسْمَاعِيلَ</i>)	Publication of <i>Book of Knowledge of Ingenious Mechanical Devices</i> . Description of mechanical devices and mechanism of action.
1245	Thomas Aquinas (1225–1274)	Reformulation of the dynamic concepts of Aristotle (384 BC–322 BC).
1500	Leonardo da Vinci (1452–1519)	Formal description of physical phenomena based on the state-of-the-art mathematical definitions. Description of several machines, including “flying machines,” and a rudimentary theoretical discourse on the respective mechanism of action for several dynamic systems.
1600	William Gilbert (1544–1603)	Publication about events and scientific exploration of earth's phenomena: <i>Terrella</i> . Additional work was on the description of the magnetic field and magnet in <i>De Magnete, Magneticisque Corporibus, et de Magno Magnete Tellure</i> .
1617	Johannes Kepler (1571–1630)	Kepler's third law of planetary motion, based on the collected data by Tycho Brahe (1546–1601).
1623	Galileo Galilei (1564–1642)	Experimentation; experimental design, publication: ‘Il saggiaiore’ (<i>The Assayer; Mechanics</i>). Galileo described the influence of air as a resistive force in comparison to water for the first time. First principles of mechanics: description of laws of motion (falling bodies; gravitational acceleration), projectile motion (ballistics), and inertia, before Sir Isaac Newton (1643–1727). Invented the pendulum clock and many more engineering feats. By some considered the father of mechanics.
1640	Francesco Maria Grimaldi (1618–1663)	Documentation that the fall of an object traverses a distance that is proportional to the square of the elapsed time, linking it to the gravitational acceleration. Collaborations with Giovanni Battista Riccioli (1598–1671).
1660	Robert Boyle (1627–1691)	Gas laws, definition of the behavior of gases.
1673	Christiaan Huygens (1629–1695)	Huygens introduced several concepts of mechanical engineering and described the mechanism of shock waves.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
ca. 1666	Sir Isaac Newton (1643–1727)	Sir Isaac Newton introduced several laws of motion: Newton's three laws of motion. This forms the macroscopic scale of the field of classical mechanics. The publication of the <i>Philosophiæ Naturalis Principia Mathematica</i> in 1685 provides detailed definitions regarding ballistic motion, circular motion (centripetal force), laws of action–reaction, gravitational acceleration, inertia, and force with respect to acceleration. Sir Isaac Newton derived the inverse square law for gravitational force in 1666. Formal introduction of the field of classical mechanics.
1698	Thomas Savery (1650–1715)	Construction of the basic steam engine.
1712	Thomas Newcomen (1664–1729)	Construction of a “atmospheric” steam engine.
1757–1769	James Watt (1736–1819)	Modern steam engine design and operation with theoretical description of operation.
	Leonard Euler (1707–1783)	Contributions to the mechanical aspects of civil engineering. Leonard Euler provided a mathematical recourse of the load applied to columns (architecture) and the associated buckling under excessive forces.
1769	Nicolas-Joseph Cugnot (1725–1804)	First operational steam-powered automobile, the predecessor to the internal combustion automobile.
1807	Thomas Young (1773–1829)	Formal introduction of the Young's modulus for elastic deformation, tying strain to stress, based on the work by Leonard Euler (1707–1783).
1830	Joseph Henry (1797–1878)	First electromotor constructed.
1851	Sir George Gabriel Stokes, 1st Baronet (1819–1903)	Creeping flow, partially applicable to seismology. Specific seismic work of Gabriel Stokes was on a human size scale, describing vibrational forces and energy related to driven oscillations while crossing bridges, and the resulting bridge collapses in his days. One of the fall-out from the bridge vibration and collapse is development of studies in metal fatigue.
1877	Ludwig Eduard Boltzmann (1844–1906)	Introduction of the field of statistical mechanics; discrete energy levels. This formed the formal introduction to quantum mechanics. Publication of the paper “On the Relation of a General Mechanical Theorem to the Second Law of Thermodynamics.”
1880	Paul-Jacques Curie (1855–1941) and Pierre Curie (1859–1906)	Discovery of electric charges emerging on the surfaces of crystals that are subjected to shear or normal stress. This is referred to as the piezoelectric effect.
1892	Jules Henri Poincaré (1854–1912)	Celestial mechanics.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1897	Joseph John Thomson (1856–1940)	Discovery of the electron; using William Crookes's vacuum tube. Joseph Thompson describes the atom as a “plum pudding” where the raisins in the spherical blob are the electrons.
1900	Max Karl Ernst Ludwig Planck (1858–1947)	Introduction of the premise of quantum theory. The energy of electromagnetic radiation is proportional to the frequency of the electromagnetic wave; discrete quanta with respect to the narrow wavelength bandwidth.
1902	Josiah Willard Gibbs (1839–1903)	Publication of his book <i>Elementary Principles of Statistical Mechanics</i> .
1905	Albert Einstein (1879–1955)	Introduction of special theory of relativity.
1909	Robert Andrews Millikan (1868–1953)	Measurement of the mass of the electron.
1916	Niels Henrik David Bohr (1885–1962)	Atomic structure definition (Bohr atomic model) and introduction to quantum theory.
1917	Ernest Rutherford, 1st Baron Rutherford of Nelson (1871–1937)	Discovery of the proton.
1920	Amalie (Emmy) Noether (1882–1935)	Theoretical connection between symmetry and conservation laws. Emmy Noether made significant contributions to a broad field of mathematical applications and the theoretical description of physics concepts. Noether worked closely with David Hilbert (1862–1943) in the early part of her career. Noether introduced two statements, the first regarded as Noether's first theorem, treating conservation laws in a manner of a stress energy tensor, posing that there is a corresponding conservation law corresponding to every differentiable symmetry of the action associated with the physical system. The Noether conservation theorem applies directly to quantum mechanics. Noether's second theorem links the symmetry of an action function for a system to the system's differential equations. The action in this case is an integral defined by the Lagrangian function, from which the behavior of the system can be derived based on the “principles of least action.”
1924	Louis-Victor-Pierre-Raymond, 7th duc de Broglie (1892–1987)	Introduction of the wave phenomenon with respect to all objects in motion. Matter wave, propagating with the de Broglie wavelength.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1925	Sir William Hamilton (1788–1856), David Hilbert (1862–1943), Max Planck (1858–1947), Albert Einstein (1879–1955), Niels Bohr (1885–1962), Werner Heisenberg (1901–1976), Louis de Broglie (1892–1987), Erwin Schrödinger (1887–1961), Pascual Jordan (1902–1980), Max Born (1882–1970), Wolfgang Pauli (1900–1958), Paul Dirac (1902–1984), John Wheeler (1911–2008), and John von Neumann (1903–1957)	Introduction of the field of quantum mechanics, the list may be extended, however the main contributors are listed. Quantum mechanics is the field of mechanics, a branch of physics, describing events on a nanoscopic scale, based on the realization that the energy distribution for a system does not always form a continuous spectrum. The work of Erwin Schrödinger (1887–1961) combined quantum mechanics with special relativity, forming a subsection of wave mechanics.
1926	1928: Paul Dirac (1902–1984); 1929 Dmitri Vladimirovich Skobeltsyn (1892–1990); 1932 Carl David Anderson (1905–1991)	Discovery of positron. Generally Carl Anderson is credited with the formal discovery (Nobel Prize).
1926	Jean Baptiste Perrin (1870–1942)	Physical proof providing the existence of molecules.
1927	Wolfgang Ernst Pauli (1900–1958) Ralph Kronig (1904–1995), George Eugene Uhlenbeck (1900–1988), Samuel Abraham Goudsmit (1902–1978), and Paul Adrien Maurice Dirac (1902–1984)	Introduction of the electron spin concept and a broad range of relativistic quantum mechanical principles.
1932	James Chadwick (1891–1974)	Discovery of the neutron.
1941	Richard Phillips Feynman (1918–1988)	Amplitude formulation of the principles of quantum mechanics under the Laplacian approach, or “many paths approach,” with equivalence to the “least action” theorem. In principle this combines the matrix formulation and the wave formulation.

Meteorology

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
3000 BC	India	Description of seasonal cycles and cloud formations, and rudimentary reference to the earth's movement around the sun.
ca. 600 BC	China; India	Documented use of magnetic compasses; the lodestone. More specific documented use dates to the Han Dynasty (ca. 206 BC).
ca. 600 BC	Thales of Miletus (ca. 624 BC–ca. 546 BC; known as Thales: Θαλῆς)	Introduction of metrology, accurate measurements of objects, phenomena, events, and conditions (e.g., atmospheric conditions).
430 BC	Democritus (of Greece) (460 BC–370 BC)	Rudimentary weather prediction processes.
430 BC	Hippocrates of Chios (ca. 470–410 BC)	Publication of the seasonal variabilities and wind velocity and direction profiles.
350 BC	Aristotle (384 BC–322 BC)	Aristotle described the initial concepts of physics, motion, time as well as astronomy concepts. Aristotle used geological and atmospheric record keeping for the prediction of weather conditions (meteorology). First documented use of a scientific approach to weather forecasting.
ca. 250 BC	Archimedes (287 BC–212 BC)	Revealed the properties that define buoyancy. The base principles relate to the tectonic plate mechanics.
50	Gaius Plinius Secundus (23–79), known as: Pliny the Elder	Publication of the magnetic action of the lodestone in his publication: <i>Naturalis Historia</i> . A rather detailed description of the use of magnetism for geographical location determination is described.
62	Hero of Alexandria [ἥρων δ' Ἀλεξανδρεὺς] (10–70)	Mathematician, physicist, and mechanical engineer who also taught pneumatics. The base of this methodology formed the principle understanding of the movement of atmospheric air masses in future years.
82	Wang Chong (27–97)	Description of the formation of rain as the result of condensed water vapor (clouds), in contrast to an “extraterrestrial” cause.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
120	Claudius Ptolemy {Ptolemaeus} [Πτολεμαῖος] (90–168)	Geographic recordings of a significant part of the Islamic and western world (i.e., Roman and Persian Empire), living in Egypt, as a Roman with Greek education. His cartography extended all the way out, including parts of China (discovered in fifteenth century). He specifically developed arithmetical techniques for calculating astronomical phenomena, under the teachings of Babylonian astronomers. Also known as: بطليموس (Batlaymus; Arabic). Combining the cartography with the ancient Chinese knowledge of the earth's magnetic field formed early recording of the location of the North and South pole, however rudimentary, only a portion of the earth had been mapped. Later documentation with a detailed world map provided an indication of the migration of the magnetic poles.
500	Varahamihira (505–587) [Devanagari: वराहमिहिर]	Detailed meteorological discourse describing atmospheric events: “Brihatsamhita.”
600	Isidore de Seville (560–636)	Description of rainbows, clouds, wind, and rain.
850	Al-Kindi (Alkindus) [Abu Yūsuf Ya‘qūb ibn ’Ishāq aṣ-Ṣabbāḥ al-Kindī (Arabic: بن يعقوب يوسف أبو الكندي الصباح إسحاق) (801–873)	Description of flow of natural media and a misconceived interpretation that the tides in the oceans are caused as the result of temperature effects, which does apply to the flow of air.
1021	Ibn al-Haytham (Alhazen) [Abū ‘Alī al-Ḥ- asan ibn al-Ḥasan ibn al-Haytham (Arabic: بن الحسن ، علي أبو الهيثم بن الحسن) (965–1040)	Description of the refraction of light during sunset and sunrise causing the discoloration of the sky. Alhazen uses geometry and his refraction theory to calculate the height of “earth’s atmosphere,” yielding approximately 80 km, which is close to the currently accepted average altitude of the mesosphere of 80 km.
1027	Avicenna [Arabic: ابن الحسين علي أبو [سينا ابن الله عبيد (ca. 980–1037)	In his <i>Book of Healing</i> there is a description of meteorology, how mountains influence the formation of clouds and weather conditions. Additional information about earthquakes and description of a meteor.
1050		Full-scale use of the compass for geographical orientation.
1121	Abu Jafar Muhammad ibn Hasan Khazini (900–971)	Study of the hydrostatic balance.
ca. 1240	Albert the Great (1193–1290)	Description of the refraction of light by an individual raindrop, hence deriving that the rainbow must be produced by little drops of air in the sky.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1269	Petrus Peregrinus of Maricourt	Formal description of the use of the compass during seafaring expeditions.
1441	Prince Munjong of Josen (1414–1452)	Description of the introduction and use of a standardized rain gauge in Korea. The rain gauge served as a tool to estimate the cross yield and from this the tax base was determined.
1450	Leone Battista Alberti (1404–1472)	First conceptual anemometer, the swinging plate wind velocity meter.
1450	Nicolas Cryfts (Nicolas of Cusa) (1401–1464)	Design and experimental verification of the hair hygrometer for the measurement of the humidity. This design is still used, next to other new technology.
1494	Christopher Columbus (1451–1506)	Description of the first experience with a cyclone; encounters with hurricane on the shores of the “Americas.”
1500	Leonardo da Vinci (1452–1519)	The preverbal “Renaissance man,” involved in all aspects of cultural evolution, science, engineering, politics, and art. Drawing of the design of the first hair hygrometer in his <i>da Vinci's Codex Atlanticus</i> . The design was created and tested in 1450 by Nicolas Cryfts (Nicolas of Cusa) (1401–1464).
1543	Nicolaus Copernicus (1473–1543); alias of Niclas Koppernigk	Introduction of the heliocentric model for the earth, sun, and close planets. This follows the statement by the astronomer from Greece: Aristarchus of Samos (ca. 310–ca. 230 BC), made more than 1700 years prior. The scientific observations made by Copernicus were validated by Tycho Brahe (1546–1601) and Johannes Kepler (1571–1630).
1590	Francis Bacon, 1st Viscount of St. Alban (1561–1626)	Regulate the general scientific methodology.
ca. 1600	William Gilbert (1544–1603)	Experimentalist. Description of magnetism, in his work <i>De magnete, magnetisque corporibus, et de magno magnete tellure</i> . The compass had been in use since 206 BC (Chinese Han Dynasty: 206 BC–220 AD; maybe even earlier, during the Qin Dynasty: 221 BC–207 BC), in the European and Persian area since the thirteenth century.
ca. 1600	Galileo Galilei (1564–1642)	Major contributor to the scientific revolution and the (re) introduction of analytical thinking in science, engineering, and general thought processes. Galileo Galilei was remanded under house arrest by the Roman Inquisition for his views and teachings where he died after 9 years. This was the trailing end of the Renaissance period.
1611	Johannes Kepler (1571–1630)	Description of the “snow-flake.”

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1614	René Descartes (1596–1650)	Introduction to vortex motion. Introduction of the concept of general corpuscular motion, extending from small (maybe referring to the undefined atom), to planetary orbits. Vortices are found in geological phenomena such as cyclones (hurricanes), maelstrom, and aspects of magma flow.
1632	Evangelista Torricelli (1608–1647)	Introduction of the barometer; essential in weather prediction; meteorology.
1650	Blaise Pascal (1623–1662)	Pascal's law, pressure in a container applies an equal force on all surface of the enclosure. The unit for pressure under atmospheric conditions uses the unit Pascal in his honor.
1660	Robert Boyle (1627–1691)	Gas laws, definition of the behavior of gases. Boyle mentioned the compression of gas relating to partial pressure of atmospheric constituents and barometric values.
1662	Sir Christopher Wren (1632–1723)	First documented use of rain gauge.
1679	Denis Papin (1647–ca. 1712)	Pressure and thermodynamic and mechanical impacts. Denis Papin worked as an assistant to both Christiaan Huygens (1629–1695) and Robert Boyle (1627–1691). His invention of the pressure cooker bears some resemblance to the conditions found in geysers.
1680	Robert Hooke (1635–1703)	Force applied by a compressed spring.
1686	Edmund Halley (1656–1742)	Study of the cause-and-effect relationship between solar heating and the occurrence of monsoon and trade winds. This work ties to the atmospheric motion. Edmund Halley also described the relationship he found between the measured atmospheric pressure and the observation altitude with respect to the sea level.
ca. 1687	Sir Isaac Newton (1643–1727)	The recognition of gravitational force provided one of the essential building blocks in the geological understanding next to cartography and the physical description of location-specific meteorologic phenomena.
1750–1800		With the advent of more sophisticated measurement instrumentation (thermometer, barometer, wind velocity meter) meteorology became more scientifically rooted, especially with the interest of a broad range of mathematicians in the dynamics of physics; thermodynamics, motion, wave propagation, and pressure perturbations. The methodology for cartography and for geographic orientation (compass) also had evolved significantly.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1732	Anders Celsius (1701–1744)	Thermometer-scale calibration based on pure water phases.
1733	Daniel Bernoulli (1700–1782)	Acoustics, mechanical vibrations, and fluid dynamic principles introduced. Definition of the fundamental frequency and higher harmonics, with supporting elaborate mathematical analysis (solutions to differential equations). This laid the foundation for seismic imaging using P-wave (primary wave; longitudinal) and S-wave (secondary wave, or shear wave [transverse]).
1735	Daniel Gabriel Fahrenheit (1686–1736)	Temperature scale in Fahrenheit based on body temperature and saltwater phases.
1743	Jean-Baptiste le Rond d'Alembert (1717–1783)	Publication on the concepts of forces and accelerating systems: <i>Traite de Dynamique</i> .
1749	Alexander White (1714–1786) and Thomas Meville (seventeenth century)	Atmospheric data collection by means of weather balloons, replacing the use of kites.
1752	Benjamin Franklin (1706–1790)	Kite experiment and the documentation of “electric current” associated with lightning bolts.
1780	Charles Theodore, Prince-Elector, Count Palatine and Duke of Bavaria (1724–1799)	Introduction of an international network of meteorologic observation stations: <i>Societas Meteorologica Palatina</i> .
1781	Charles-Augustin de Coulomb (1736–1806)	Definition of the electric field related to electric charge. The electric charge itself was still an elusive concept in those days. The meteorological implications extend out to the influence of lightning on the environmental conditions: specifically the formation of ozone.
1783	Antoine Laurent de Lavoisier (1743–1794)	Discovery of oxygen and the chemical impact.
1785	Jacques Alexandre César Charles (1746–1823)	Charles's law, expansion of gases.
1802	Luke Howard (1772–1864)	Introduction of the nomenclature for cloud formations.
1802	Joseph Louis Gay-Lussac (1778–1850)	Ideal gas law; building on the work by Robert Boyle (1627–1691), more than a century earlier.
1822	Jean-Baptiste Joseph Fourier (1768–1830)	Introduction of the use of dimensions in mathematical solution and definition of physical quantities.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1824	Nicolas Léonard Sadi Carnot (1796–1832)	Introduction to the second law of thermodynamics, with heat exchange implications providing explanation to natural phenomena.
1827	Robert Brown (1773–1858)	Brownian motion.
1835	Gaspard-Gustave de Coriolis (1792–1843)	Influence of the earth's rotation on the flow movement and direction: Coriolis force.
1840	Jean Léonard Marie Poiseuille (1799–1869) and Gotthilf Heinrich Ludwig Hagen (1797–1884)	Pressure drop for incompressible fluids with respect to laminar flow. Reference to meteorology, wind formation based on arctic versus topical pressure systems.
1843–1848	James Prescott Joule (1818–1889)	Empirical verification of the first law of thermodynamics: stating the equivalence of heat and work. This applies to both the source energy for the persisting liquid core (magma) and the work performed by volcanic eruptions and earthquakes.
1848	William Thomson, 1st Baron Kelvin (i.e., Lord Kelvin) (1824–1907)	Absolute temperature scale: Kelvin. Reference base for geological events and meteorology.
1850	Rudolf Julius Emanuel Clausius (1822–1888)	Recognition of two basic principles of thermodynamics, later introduced by means of the first and second law of thermodynamics, respectively: energy is constant and entropy tends toward a maximum. Clausius introduced the parameter U , representing the internal energy. Publication of book <i>On the Motive Power of Heat, and on the Laws Which Can Be Deduced from It for the Theory of Heat</i> . Clausius introduced what is now regarded the second law of thermodynamics in 1865 (referred to by William John Macquorn Rankine [1820–1872] as the “thermodynamic function”), as part of any natural thermodynamic process, the sum of the entropies of the participating systems will increase. The heat exchange applies directly to solar heating and the formation of weather (and environmental) conditions.
1851	Jean Bernard Léon Foucault (1819–1868)	Foucault pendulum, illustrating the impact of the earth's rotation on motion.
1851	Sir George Gabriel Stokes, 1st Baronet (1819–1903)	Creeping flow, partially applicable to air stream Furthermore, the work of Stokes contributed to the development of the scientific and engineering support for the construction of high-rise buildings in earthquake-prone geographical regions.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1852	James Prescott Joule (1818–1889) and William Thomson, 1st Baron Kelvin {Lord Kelvin} (1824–1907)	Joule–Thomson effect: rapidly expanding gas leads to a reduction in the temperature of the gas, even offering the potential for a phase change to solid, or liquid. Sometimes also found as the Joule–Kelvin effect. Cloud formation and the release of rain and snow fall under this topic. The Joule–Thomson effect is an isenthalpic process, which entails that the enthalpy of the fluid is constant during the process, which applies to Joule–Thomson inversion temperature, described in the Linde cycle (Carl von Linde [1842–1934]), offering conditions leading to cloud formation.
1859	James Clerk Maxwell (1831–1879)	Description of the distribution law of molecular velocities; also applies to atmospheric conditions.
1868	William Thomson, 1st Baron Kelvin (i.e., Lord Kelvin) (1824–1907) and Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Kelvin–Helmholtz wave phenomenon (Kelvin–Helmholtz instability), resulting from a velocity shear in a moving single continuous fluid or at the interface between two fluids. The two fluids may be the same medium at different temperature and hence different respective density. Described separately by Lord Kelvin (1871) and Hermann von Helmholtz (1868). This phenomenon is most clearly observable for rolling cloud formations, but is also experienced in deep water (ocean), the corona of the sun, and applies to Jupiter’s “red spot.”
1873	James Clerk Maxwell (1831–1879)	Theory of electromagnetic radiation: <i>Treatise on Electricity and Magnetism</i> . James Maxwell made use of the prior work by Wilhelm Eduard Weber (1804–1891) and Johann Carl Friedrich Gauss {Gauß} (1777–1855). Solar radiation heats the earth’s surface causing gradients in temperature or discontinuities resulting in the movement of air masses, next to local temperature sensation.
1876	Josiah Willard Gibbs (1839–1903)	Chemical potential, an energy constituent within the Gibbs free energy, setting the standard for the energy content and exchange with respect to phase transitions. Thermodynamic concept describing the energy that can be released or absorbed during a chemical process.
1900	Ludwig Eduard Boltzmann (1844–1906)	Thermodynamic concepts with respect to heat exchange in the earth’s volume, specifically defining the entropy. Boltzmann equation for statistical mechanics, introduced by Ludwig Boltzmann between 1872 and 1875, reformulated by Max Karl Ernst Ludwig Planck (1858–1947). For certain systems also addressed as the Gibbs entropy formula, after Josiah Willard Gibbs (1839–1903).
1902	Philippe Teisserenc de Bort (1855–1913)	Description of several of the earth’s atmospheric layers: stratosphere, tropopause, and troposphere. Additional credit for the outline of the lower part of the atmosphere goes to Richard Assmann (1845–1918).

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1903	Vagn Walfrid Ekman (1874–1954)	Discovery of layered structure of the ocean waters, in similar arrangement as the earth's atmosphere.
1904	Vilhelm Friman Koren Bjerknes (1862–1951)	Introduction of the mathematical modeling requirements for weather prediction.
1905	Albert Einstein (1879–1955)	Recognition and description of the mesosphere.
1912	Theodore von Kármán (1881–1963)	Description of the “von Kármán vortex street.” Turbulent flow profile, first observed and described by Arnulph Henry Reginald Mallock (1851–1933) and also by Henri Claude Bénard, (1874–1939)
1917	Sir Horace Lamb (1849–1934)	Introduction of the concept of evanescent waves, referred to as Lamb waves. Elastic waves traveling between two superimposed layers: inversion surface, a third layer forcing itself between the two stacked layers. The resulting compression and extension provides a line pattern of cloud formation, formed in the low-pressure parts of the wave pattern; expanding air forms condensation. Also known as “morning glories.”
1922	Jacob Aall Bonnevie Bjerknes (1897–1975), Vilhelm Friman Koren Bjerknes (1862–1951), Halvor Skappel Solberg (1895–1974) and Tor Bergeron (1891–1977)	Formulation of pressure fronts and the general movement of air masses.
1926	John Patterson (1872–1956)	Three cup anemometer, improvement on the work of Leone Battista Alberti (1404–1472).
1938	Guy Stewart Callendar (1898–1964)	Description of the concept of global warming resulting from the insulating layer of carbon dioxide exhaust in the atmosphere.
1941		Introduction of “pulse radar” used for the localization and determination of the geographical extend of precipitation.
1960		Launch of the first weather satellite.
1971	Tetsuya Theodore “Ted” Fujita [藤田 哲也] (1920–1998)	Introduction of the Fujita scale to quantify the magnitude of tornadoes, cyclones, hurricanes, and typhoons.
1994	Andreas Pflietsch (1958–)	Sonic anemometer.
1995	Roger Lee Easton (1921–2014)	Development of the global positioning concept (GPS).

Nuclear

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
13.8 billion years BC	Georges Henri Joseph Édouard Lemaître (1894–1966) and Edwin Powell Hubble (1889–1953)	“The Big Bang”; In 1927 the expanding universe was recognized.
350 BC	Aristotle (384 BC–322 BC)	The word “energy” has the Greek origin “Enérgeia” [Greek: ἐνέργεια], which was documented by Aristotle, “enérgeia” does not translation directly into English, the meaning resembles “being at work.”
ca. 1800	John Dalton (1766–1844)	Introduction of the “law of multiple proportions” describing the atomic concept based on chemical reactions taking place in ratios of small whole numbers.
1870	Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Unofficial introduction to the mechanism of action for nuclear fusion.
1896	Wilhelm Conrad Röntgen (1845–1923)	Discovery of X-ray radiation.
1896	Henri Becquerel (1852–1908)	Emission of “Becquerel rays” from uranium salts, later identified as alpha particles. Becquerel already recognized that this emission was different from X-ray since it was deflected by means of an applied external magnetic field. Conceptual introduction to the field of radioactivity.
1897	Joseph John Thomson (1856–1940)	Discovery of the electron; using William Crookes’s vacuum tube.
1897	Marie Skłodowska-Curie (1867–1934)	Discovery of radioactive isotopes. Marie Curie introduced the term “radioactivity.”
1899	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Emission of alpha particle.
1900	Max Karl Ernst Ludwig Planck (1858–1947) and James Clerk Maxwell (1831–1879)	Formal description of the photon and the energy associated with the electromagnetic wave.
1903	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Discovery of the nuclear decay half-life.
1903	Marie Skłodowska-Curie (1867–1934) and Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Quantification of nuclear decay.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1906	Dmitri Ivanovich Mendeleev (1834–1907)	Periodic Table of Elements.
1908	Johannes Geiger (1822–1945) and Ernest Rutherford (1871–1937)	Development of the Geiger counter, used to measure radioactive radiation.
1909	Francis Aston (1877–1945)	Mass spectrometer mass separation of closely separated isotopes. Highly sensitive mass spectrometer design.
1911	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Rutherford scattering on nuclear level, indication of the existence of the proton. The proton itself was not mentioned until 1932, this time again by Ernest Rutherford.
1913	Niels Henrik David Bohr (1885–1962)	Bohr atomic model.
1913	Frederick Soddy (1877–1956)	Formal introduction of the isotope concept.
1914	Niels Henrik David Bohr (1885–1962)	Description of the atomic energy layer model; hydrogen (Bohr atomic model).
1915	Sir Ernest Marsden (1889–1970)	Artificial transmutation, associated with radon enclosed by vacuum.
1918	Paul Scherrer (1890–1969)	X-ray diffraction, crystal structure. Nuclear energy development. Established the CERN institute in Switzerland as one of the founders. Directed the construction of the first cyclotron in 1940.
1919	Ernest Rutherford (1871–1937)	Artificial transmutation, hydrogen formation resulting from collisions of alpha particles with nitrogen, also generating oxygen and gamma rays.
1923	Arthur Holly Compton (1892–1962)	Description of the deflection of photons by a charge unit, generally an electron, potentially the nucleus: Compton effect.
~1925		Recognition of the “Coulomb barrier” in nuclear collision, providing a “tunneling” effect for the release of alpha particles.
1927	Werner Karl Heisenberg (1901–1976)	Quantum uncertainty principle.
1927	Paul Adrien Maurice Dirac (1902–1984)	Description of antimatter.
1928	Johannes Geiger (1822–1945) and Walther Müller (1905–1979)	Introduction of an improved Geiger counter: the Geiger–Müller counter, using ionization of a confined gas.
1931	Wolfgang Ernst Pauli (1900–1958)	Theoretical introduction of the neutrino. The experimental verification of the existence of the neutrino was not until 1956 by Frederick Reines (1918–1998) and Clyde Cowan, Jr. (1919–1974).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1931	Carl David Anderson (1905–1991)	Discovery of the positron, antiparticle for the electron. The “positron” was predicted by Paul Adrien Maurice Dirac (1902–1984) in 1929.
1932	Sir James Chadwick (1891–1974)	Discovery of the neutron. Student of Ernest Rutherford (1871–1937).
1934	Leo Szilard (1898–1964)	Recognition of nuclear decay chain reactions.
1934	Hideki Yukawa [湯川 秀樹], (1907–1981)	Introduction of mesons and the concept of antimatter.
1934	Ida Noddack (1896–1978)	Formal introduction of the concept of “fission,” however not recognized by her peers at the time. The fission phenomenon was only recognized when announced by Enrico Fermi (1901–1954) later that year.
1934	Enrico Fermi (1901–1954)	Interaction of slow neutron with nuclei and the resulting decay into different elements, including aluminum and uranium.
1935	Arthur Dempster (1886–1950)	Discovery of the lighter uranium isotope: uranium-235.
1936	Otto Hahn (1879–1968) and Lise Meitner (1878–1968)	Neutron collision of uranium-induced decay examination.
1937	Carl David Anderson (1905–1991), Seth Henry Neddermeyer (1907–1988), Jabez Curry Street (1906–1989), and Edward C. Stevenson ()	Confirmation of the existence of the meson, and muon.
1938	Niels Henrik David Bohr (1885–1962) and John Archibald Wheeler (1911–2008)	Formal description of the nuclear fission process.
1939	J. M. B. Kellogg	Discovery of a finite quadruple moment for the deuteron, requiring a noncentral (tensor) nuclear force configuration.
1940	Otto Robert Frisch (1904–1979)	Development of the detonation mechanism for the first atomic bomb.
1940+	Julius Robert Oppenheimer (1904–1967)	Manhattan project: fission reaction. Prominent members: Arthur Compton (1892–1962), Enrico Fermi (1901–1954), Eugene Wigner (1902–1995), and dozens more.
1947	George Dixon Rochester (1908–2001), Clifford Charles Butler (1922–1999)	Discovery of the subatomic particle: the “kaon,” k-meson. Introduction of the “strangeness” concept for quarks, although the quark concept had not been introduced. In the elementary particle phenomenology the kaon is a bound state of an up- or down quark with a strange quark (antiquark).

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1947	Maria Goeppert-Mayer (Göppert) (1906–1972)	Theoretical concept development for the understanding of nuclear forces, based on a shell model, similar to the atomic electron model.
1947	William Webster Hansen (1909–1949)	Linear accelerator installation at Stanford University, California.
1950	Maria Goeppert-Mayer (Göppert) (1906–1972)	Introduction of the nuclear shell model for atomic nuclei.
ca. 1952	Ludwig von Helmholtz (1821–1894), Lyman Strong Spitzer, Jr. (1914–1997), and Ronald Richter (1909–1991) and Edward Teller (1908–2003)	Nuclear fusion investigation and start of experimentation. The process was in principle described by Hermann Ludwig Ferdinand von Helmholtz (1821–1894), but is continuously in action at the sun's surface.
1955	Obninsk Nuclear Power Station, Russia	First nuclear power station for energy generation.
1956	Frederick Reines (1918–1998) and Clyde Lorrain Cowan, Jr. (1919–1974)	Experimental confirmation of the neutrino introduced in 1931 by Wolfgang Pauli (1900–1958).
1958	Stanley Mandelstam (1928–2016)	Introduction of Mandelstam variables associated with the concept of “crossing symmetry,” defining numerical quantities, which encode the energy, momentum, and scattering angles of particles in a deflection process described in a Lorentz-invariant fashion.
1958	Lev Davidovich Landau [Russian: Лёв Давидович Ландау] (1908–1968), Arkady Beynusovich Migdal [Russian: Аркадий Бейнусович (Бенедиктович) Мигдаль] (1911–1991)	Theory of interacting electrons, specifically with respect to solids; condensed matter physics.
1961	Murray Gell-Mann (1929–)	Description of elementary particles, eightfold way of defining “strangeness” for the quark. Formal introduction of the elementary particle “quark” concept, the building blocks for protons and neutrons. The “quark” name is based on an expression in the book <i>Finnegans Wake</i> by James Joyce.
1964	Charles Hard Townes (1915–2015), Nikolay Gennadiyevich Basov [Николай Геннадиевич Басов] (1922–2001) and Aleksandr Mikhailovich Prokhorov [Александр Михайлович Прохоров] (1916–2002)	Quantum electronics.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1970	Sheldon Lee Glashow (1932–), John Iliopoulos (1940–), and Luciano Maiani (1941–)	Introduction of the charm quark.
1974	Burton Richter (1931–) and Samuel Chao Chung Ting [Chinese: 丁肇中] (1936–)	Description of charm for the quark.
1975	Martin Lewis Perl (1927–2014)	Discovery of the tau lepton.
1977	Leon Max Ledderman (1922–)	Discovery of the “beauty” and “bottom” designation for quarks.
1978		Discovery of the “gluon” with the assistance of the PLUTO, the first electromagnetic superconductive solenoid located in Hamburg, Germany.
1983	Collider Detector at Fermilab	World’s first and at the time highest-energy particle accelerator, colliding antiprotons and protons propelled to center-of-mass energy reaching 2 TeV.
1995	Wolfgang Ketterle (1957–), Eric Allin Cornell (1961–), and Carl Edwin Wieman (1951–)	Experimental verification of Bose–Einstein condensation.
2012	François Baron Englert (1932–) and Peter Ware Higgs (1929–)	Higgs boson (126 GeV) discovery in the Large Hadron Collider at CERN, Geneva, Switzerland. The Large Hadron Collider construction started in 1998 and produces particle acceleration with respective energy levels for protons at up to 4 teraelectronvolts (0.64 microjoules), or lead nuclei: 2.76 TeV per nucleon or 574 TeV per nucleus. The proton energy level was increased to 6.5 TeV in 2015.

Optics

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
~300 BC	Euclid (of Alexandria) (323 BC–283 BC)	Description that light travels in straight lines and defines his version of the law of reflection in his publication: <i>Optica</i> . Euclid was a proponent of “extramission for vision; believed that vision involves rays going from the eyes to the object observed. Euclid also described the relationship between the apparent sizes of objects and the angles with the optical axis of the eye: angular magnification.
~150 BC–100 BC	Hero (also known as Heron) of Alexandria (10–70)	Hero showed, by a geometrical means, how the actual path outlined by a ray of light reflected from a plane mirror is shorter than any respective other path resulting from reflected that might be drawn between the source and the chosen point of observation, publication <i>Catoptrica</i> .

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
~140 AD	Claudius Ptolemy (ca. 100–ca. 168)	In a translation from an Arabic publication assumed to be by Ptolemy in the twelfth century into Latin Ptolemy presents a study of refraction, which continues to describe the phenomena of atmospheric refraction. He suggested that the angle of refraction at the interface of two media is proportional to the angle of incidence.
1021	Abū ‘Alī al-Ḥasan ibn al-Ḥasan ibn al-Ḥaytham [Arabic: الحسن بن الحسن، علي أبو الهيثم بن], Alhazen (ca. 965–1040)	First documented recognition of the refraction mechanism of action. In his investigations, Alhazen used spherical and parabolic mirrors and was aware of spherical aberration. He also investigated the magnification produced by lenses and atmospheric refraction. His work was translated into Latin and became accessible to later European scholars. Publication: “Risala fi l-Daw” (<i>Treatise on Light</i>) as a supplement to his <i>Book of Optics</i> . He discusses the meteorology of the rainbow, the density of the atmosphere, and various celestial phenomena, including the eclipse, twilight, and moonlight.
1088	Shen Kuo or Shen Gua [Chinese: 沈括] (1031–1095)	In his Dream Pool Essays (梦溪笔谈) a vivid descriptions of tornadoes, that rainbows were formed by the shadow of the sun in rain, occurring when the sun would shine upon it, and the curious common phenomena of the effect of lightning that, when striking a house, would merely scorch the walls a bit but completely melt to liquid all metal objects inside.
~1220	Robert Grosseteste (1175–1253)	Magister scholarum of the University of Oxford and a proponent of the view that theory should be compared with observation, Grosseteste considered that the properties of light have particular significance in natural philosophy and stressed the importance of mathematics and geometry in their study. He believed that colors are related to intensity and that they extend from white to black, white being the purest and lying beyond red with black lying below blue. The rainbow was conjectured to be a consequence of reflection and refraction of sunlight by layers in a “watery cloud” but the effect of individual droplets was not considered. He held the view, shared by the earlier Greeks, that vision involves emanations from the eye to the object perceived.
ca. 1240	Albert the Great (1193–1290)	Description of the refraction of light by an individual raindrop, hence deriving that the rainbow must be produced by little drops of air in the sky.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
~1267	Roger Bacon (1214–1294)	Roger Bacon was a follower of Robert Grosseteste (1175–1253) at Oxford. Bacon elaborated on Grosseteste's work on optics. He concluded that the speed of light is finite and its propagation is similar to the propagation of sound. In his publication <i>Opus Maius</i> , Bacon provides a description of the magnification of small objects by means of rudimentary convex lenses and suggested that the use of external lenses could find application in the correcting defective eyesight. He also recognized the formation of the rainbow due to “reflection” of sunlight from (within) individual raindrops.
~1270	Witelo (ca. 1220–ca. 1278)	Compilation of a standard text on optics: <i>Perspectiva</i> , to be used for several centuries. Witelo published a method of machining parabolic mirrors from iron. Witelo also performed and documented observations on refraction. He recognized that the angle of refraction is not equal to the angle of incidence, however he did not report any observation of total internal reflection.
1303	Bernard de Gordon (1270–1330)	A physician, he mentioned the use of spectacles as a way of correcting far-sightedness (hyperopia).
1304–1310	Theodoric (Dietrich) of Freiberg (1250–1310)	Theodoric explained the formation of a rainbow as the result of refraction and internal reflection within individual raindrops. He provided a detailed explanation for the appearance of a primary and secondary rainbow but, following earlier established belief and scientific interpretations, he considered color to rise from a combination of different proportions of darkness and brightness.
1558	Giambattista della Porta (1535–1615)	Incorporation of a lens in the opening of a camera obscura significantly improved the image formation capabilities.
~1590	Zacharius Janssen (1585–1632)	Constructed a compound microscope with a converging objective lens and a diverging eye lens.
1604	Johannes Kepler (1571–1630)	Suggestion that the radiant intensity (radiance) of light from a point source varies inversely with the square of the distance from the source in his book <i>Ad Vitellionem Paralipomena</i> . Introduction of the notion that light can be propagated over an unlimited distance and that the velocity of light propagation is supposedly infinite. Kepler also described vision as a consequence of the formation of an image on the retina resulting from light passing through the lens in the eye, and additionally correctly described the causes of “far-sightedness” (hyperopia) and “near-sightedness” (presbyopia).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1604	Johannes Kepler (1571–1630)	Formal introduction of the term “camera obscura.”
1608	Hans Lippershey (1570–1619)	Construction of a telescope based on a converging objective lens and a diverging ocular lens configuration.
1609	Galileo Galilei (1564–1642)	Constructed his own version of the telescope design introduced by Hans Lippershey (1570–1619) and used it for astronomical observations.
1610	Galileo Galilei (1564–1642)	Using his telescope, Galileo reported a broad scale of astronomical discoveries including the four (4) moons of Jupiter.
1611	Giovanni Demisiani (?–1614)	Introduced the term “telescope” for his optical device with three times (3X) magnification.
1611	Johannes Kepler (1571–1630)	Kepler presents the lens principles involved in the convergent, respectively, divergent properties applied to microscopes and telescopes in his publication <i>Dioptrice</i> . Based on this publication the “power” of a lens is expressed in diopters. In the same treatise, Johannes Kepler proposes the construction of a telescope using a converging objective and a converging ocular lens. This concept of the combination of lenses is still known as the telephoto lens. He also described the process and conditions of total internal reflection, but was unable to find a suitable mathematical relationship between the angle of incidence and the angle of refraction. Willebrord Snel (1591–1626) resolved this issue in 1621.
~1618	Christopher Scheiner (1573–1650)	Constructed a telescope of the type suggested by Johannes Kepler (1571–1630) with converging objective and eye lenses. This type of telescope has since become known as the “astronomical telescope”. So far no exact date for the construction of the first instrument of this design.
1621	Willebrord Snel (Snellius) van Royen (1591–1626)	Description of the relationship between the angle of incidence and angle of refraction at the interface when light passes from one transparent medium to another: Snell’s law.
1647	Bonaventura Francesco Cavalieri (1598–1647)	Derivation of the relationship between the radii of curvature for the respective two surfaces of a thin lens and the resulting focal length.
1657	Pierre de Fermat (1601–1665)	Introduction of the “mathematical” principle of “least time.” Based on this, a ray of light follows the path which takes the least amount of time to its destination. This shortest time path-length principle is consistent with Snell’s law of refraction.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1663	James Gregory (1638–1675)	Suggested the use of a converging mirror to be used as the objective of a telescope to mitigate for color aberrations, in his 1663 publication <i>Optica Promota</i> ; design of the “Gregorian reflecting telescope.” The Gregorian reflecting telescope was first built by Robert Hooke (1635–1703) in 1668.
1665	Francesco Maria Grimaldi (1618–1663)	Grimaldi’s observations of diffraction in the publication <i>Physico-Mathesis de lumine, coloribus et iride</i> (published posthumously). These were his observations regarding the passage of white light through small apertures. Grimaldi expressed his hypothesis that light is a fluid that exhibits wave-like motion.
1665	Robert Hooke (1635–1703)	Publication <i>Micrographia</i> , description of a compound microscope having both a converging objective lens and a converging ocular lens. In the same publication Hooke described his observations of the color displays produced in films of oil on water, flakes of mica, and in soap bubbles. He recognized that the color produced by light interaction with mica flakes is related to the thickness of the medium; however, he was unable to establish a specific relationship between thickness and obtained color. Hooke also advocated his own wave theory for the propagation of light.
1666	Sir Isaac Newton (1643–1727)	Description of the splitting up of white light into its spectral component colors when it passes through a prism.
1668	Robert Hooke (1635–1703)	Construction of the Gregorian reflecting telescope after the design by James Gregory (1638–1675) in 1663, using a reflecting converging mirror.
1668	Sir Isaac Newton (1643–1727)	Construction of the first reflecting telescope, in an attempt to compensate for chromatic aberration experienced by a refracting telescope.
1669	Rasmus Bartholinus (1625–1698)	Discovery of the double refraction in calcite.
1672	Sir Isaac Newton (1643–1727)	Documentation of the dispersion of sunlight passing through a prism. Newton concluded that the light emitted by the sun is composed of different colors, which are individually refracted by glass to different extents.
1676	Olaus (Ole) Christensen Rømer (Roemer) (1644–1710)	Deduced that the speed of light is finite based on his and his contemporary researchers’ detailed observations of the eclipses of Jupiter’s moons. From Rømer’s data, a value of about $2 \times 10^8 \text{ m.s}^{-1}$ can be obtained.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1678	Christiaan Huygens (1629–1695)	Publication <i>Traite de Lumiere</i> in 1690, to the Academie des Science in Paris, introduction of the Huygens wave theory of light. He considered that light is transmitted through an aether, made up of small elastic particles, each of which can act as a secondary wave source based on the wave mechanism Huygens was able to explain the majority of the known propagation characteristics of light, including discovery by Bartholinus regarding the double refraction in calcite.
1704	Sir Isaac Newton (1643–1727)	In his publication <i>Opticks</i> , Newton presented his corpuscular view for light, but that the corpuscles are able to perform waves in the aether. The corpuscular nature of light was based on the fact that light travels in straight lines whereas waves can refract (bend) into the shadow region of the object.
1727	James Bradley (1693–1762)	Bradley calculated the speed of light based on observations of the “aberration” of light from stars while attempting to detect stellar parallax, relying on the apparent motion of a star associated with the to be determined value of the speed of light in relation to the speed of the earth in its solar orbit. Explanation of the projection path aberration of light emitted by stars by forming the vector sum of the orbital velocity of the earth “ v ” next to the free space velocity of light “ c ”, and showed that the angle of aberration was a function of the ratio of these velocities: “ v/c ”. Based on this formulation Bradley showed that the revolution of the earth around the sun correctly accounted for the observed cyclic change in the optical aberration of star light rays. In comparison, the anti-Copernicans, which were still around in large numbers in the first half of the eighteenth century, were unable to refute this explanation of the change. Bradley’s work is the first of many instances that seemed to show (erroneously) that the value of the velocity of light depends on the motion of the observer.
1729/1733	Chester Moore Hall (1703–1771)	Construction of achromatic compound lenses using components consisting of glasses with different refractive indices. Construction of first refracting telescope that has chromatic aberration correction.
1752	Thomas Melvill (1726–1753)	Optical spectra imbedded in the light emission from flames, consisting of metals or salts; characteristic lines of representing the elements that define the constituents of the flame.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1801	Thomas Young (1773–1829)	Assisted in the development of the wave theory by demonstration of the interference properties of light.
1802	William Hyde Wollaston (1766–1828)	Discovery of the dark lines in the solar spectrum, but he was unable to interpret them in accordance with contemporary scientific knowledge.
1808	Étienne-Louis Malus (1775–1812)	Observed the light reflecting from the windows of the Palais Luxembourg in Paris through a calcite crystal as it was rotating, Malus uncovered an effect, which was later attributed to the polarization of light resulting from reflection.
1814	Joseph von Fraunhofer (1787–1826)	Rediscovery and description of the dark lines in the solar spectrum, originally noticed and documented by William Hyde Wollaston (1766–1828) in 1802 and determined the respective (not known at the time); “wavelength” locations with improved precision: Fraunhofer lines.
1815	Sir David Brewster (1781–1868)	Described the polarization direction for light resulting from reflection: Brewster angle.
1816	Augustin-Jean Fresnel (1788–1827)	Rigorous mathematical treatment of diffraction and interference phenomena illustrating that these phenomena can be explained based on a wave theory of light.
1816–1817	Augustin-Jean Fresnel (1788–1827) and Dominique François Jean Arago (1786–1853)	Interference of polarized light and the interpretation by Thomas Young (1773–1829), lead to the conclusion that light waves are transverse. Prior to this point in time the general assumption had been that electromagnetic radiation (light) has a longitudinal wave profile.
1819	Joseph von Fraunhofer (1787–1826)	Description of the diffraction of light by gratings. The gratings were initially made by winding rows of fine wires around screws lined up in parallel.
1821	Augustin-Jean Fresnel (1788–1827)	Presented the mathematical laws enabling the calculation of the radiant intensity (radiance) and direction of polarization for light reflected and refracted from an interface.
1823	Joseph von Fraunhofer (1787–1826)	Publication of the theory of diffraction.
1828	William Nicol (1770–1851)	Invention of the prism made from two calcite components, creating polarization of the transmitted light with respect to the two main axes: Nicol prism.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1834	John Scott Russell (1808–1882)	Observation of what is now referred to as a “solitary waves” and “wave of translation” based on his observations of a wave caused by a boat being drawn along the length of the Union Canal in Scotland. John Russell noticed how the wave travelled great distances without apparent change of shape. The study of solitary waves led to the solitons concept for optics, defining the light propagation in fiber-optics.
1835	George Biddell Airy (1801–1892)	Diffraction pattern produced by a circular aperture; associate resolution consequences: Airy disk.
1840	Carl Zeiss (1816–1888)	Lens fabrication initiated in Jena, Germany.
1845	Michael Faraday (1791–1867)	Rotation of the plane of polarization for light that is passed through glass exposed to a magnetic field: Faraday effect.
1847	Carl Zeiss (1816–1888)	Full-scale production of optical microscopes (Carl Zeiss AG, previously Carl Zeiss Jena).
1849	Armand Hypolite Louis Fizeau (1819–1896)	Speed of light measurement using a rotating toothed wheel to create an alternating pulsation of light beam. Fizeau made the first nonastronomical (nonvacuum) determination of the speed of light (in air), deriving a value of $313,300,000 \text{ m.s}^{-1}$. Note that the current accepted and verified speed of light in vacuum is $299,792,458 \text{ m.s}^{-1}$.
1849	Louis Pasteur (1822–1895)	Investigation of molecular asymmetry, joining his knowledge of crystallography, chemistry, and optics to obtain the optical polarization rotation. In specific, the reaction of tartaric acid derived by chemical synthesis under biological conditions or artificially. The reactions produce two mirror image molecules, with opposing effective rotated angle of polarization for the transmitted light: optical activity. The organic form of the product only has one rotation angle. Pasteur hence concluded that the molecule must be asymmetric and can have two forms, resembling left versus right hand.
1850	Jean Bernard Léon Foucault (1819–1868)	Foucault determined the speed of light in atmospheric air using a rotating mirror method, deriving a value of $298,000,000 \text{ m.s}^{-1}$. In the same year, Foucault used the same rotating mirror method to determine the speed of light in stationary water and found it to be less than in air. In 1851 Léon Foucault also positioned a pendulum with a string length of 67 meter in Paris, France, to illustrate the rotation of the earth, providing an arc rotation of the swing path in clockwise direction by 11 degree per hour; full circle in 37.2 hours.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1855	David Alter (1807–1881)	Description of the spectrum of hydrogen and other gases.
1859	Armand Hippolyte Louis Fizeau (1819–1896)	Experimental observation that the velocity of light in water is affected by flow of the water, the incremental change in the velocity of light being about a half of the velocity of the flowing water.
1860	Robert Wilhelm Eberhard Bunsen (1811–1899) and Gustav Robert Kirchhoff (1824–1887)	Recordings of the emission spectra of alkali metals in flames. Recognition of dark lines in the spectrum arising from absorption when illuminated by a bright light source through the flame. These dark lines are identical to the spectral lines observed in the solar spectrum observed by William Hyde Wollaston (1766–1828) and Joseph von Fraunhofer (1787–1826) in 1803: Fraunhofer lines, and it was argued that these lines in the sunlight are due to the absorption of light by gases in the solar atmosphere that are cooler than those “emitting the light” (not much was known about the mechanism-of-action of the sun, based on contemporary knowledge an oxidizing gas produces light).
1865	James Clerk Maxwell (1831–1879)	Combining his insights in the studies of the equations describing electric and magnetic fields, he derived that the speed of an electromagnetic wave should, within experimental error, be identical to the speed of light. Maxwell concluded from this that light is electromagnetic wave energy.
1869	John Tyndall (1820–1893)	Experimental studies of the light scattering pattern produced by aerosols.
1871	John William Strutt, third Baron Rayleigh (1842–1919)	Introduction of a general law relating the radiance of light scattered from small particles as a function of the wavelength, for particle dimensions smaller than the wavelength: Rayleigh scattering. This stand in contrast to Mie scattering (Gustav Mie [1869–1957]), where the scattering dimensions are larger than the wavelength. He also constructed a “zone plate” which resulted in focusing of light by Fresnel diffraction.
1873	Ernst Karl Abbe (1840–1905)	Detailed theory of image formation under observation by means of the microscope, specifically the resolution: Abbe criterion.
1874	Jacobus Henricus van't Hoff (1852–1911) and Joseph Achille Le Bel (1847–1930)	Each independently observed the optical activity (rotated polarization angle of the transmitted light) for carbon compounds. They both derived that this can be explained by a four (4)-way bound carbon atom (chemical saturation).
1875	John Kerr (1824–1907)	Quadratic electro-optic effect in glass: Kerr effect.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1879	Josef Stefan (1825–1893)	Publication of an empirical relationship defining the total radiant energy emitted from the surface of a body per unit time to be proportional to the fourth power of the absolute temperature of that body.
	Sir Joseph Wilson Swan (1828–1914)	Demonstration of an incandescent light bulb with a carbon filament.
1879	Thomas Alvin Edison (1847–1931)	Development and sale of a working electric lamp using cotton as a carbon filament.
1882	Albert Abraham Michelson (1852–1931)	Michelson interferometer.
1885	Johann Jakob Balmer (1825–1898)	Definition of an empirical formula describing the wavelength position of the emission lines in the visible part of the hydrogen. Spectrum: Balmer series.
1887	Albert Abraham Michelson (1852–1931) and Edward William Morley (1838–1923)	Failure to verify the illusive concept of “luminiferous aether” (in fact, electromagnetic radiation does not require an “aether”) by correlation of speed of light to the direction in which the light beam moves: the Michelson–Morley experiment.
1887	Heinrich Rudolf Hertz (1857–1894)	Discovery of the photoelectric effect, primarily by accident. Heinrich Hertz experimentally proved the electromagnetic wave concept, theoretically described by James Clerk Maxwell (1831–1879). Heinrich Hertz is a nephew of the Gustav Ludwig Hertz (1887–1975).
1890	Otto Heinrich Wiener (1862–1927)	Recognition of standing waves produced by light reflecting at normal incidence from a silver mirror. Nodes and antinodes in the standing electromagnetic wave were recorded photographically illustrating a node at the mirror surface, yielding the electric field to be zero (no electric field inside a conductor). From this it was derived that the electric component of the electromagnetic wave carries the more important effect, at least for this time of detection.
1891–1892	Ludwig Mach (1868–1951) and Ludwig Louis Albert Zehnder (1854–1949)	Description of the respective interferometer efforts of Ludwig Mach in 1892 and Ludwig Zehnder in 1891 independently, what has become known as the Mach–Zehnder interferometer with the ability to monitor changes in refractive index, and inherent density, with respect to compressible gas flows. The Mach–Zehnder interferometer has found apropos applications in the field of aerodynamics. The optical path for the interferometer is governed by the Fermat principle (Pierre de Fermat [1601–1665]). Ludwig Mach is the son of Ernst Waldfried Josef Wenzel Mach (1838–1916).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1896	Wilhelm Carl Werner Otto Fritz Franz Wien (1864–1928)	Description of the spectral distribution (peak emission wavelength) of radiation from a black body as a function of the temperature of the body.
1896	Pieter Zeeman (1865–1943)	Observation of the broadening of the spectral lines emitted by an atomic source when the source is exposed to an external magnetic field.
1899	John William Strutt, the 3rd Baron Rayleigh (1842–1919)	Explanation of the principles for the blue color of the sky as well as the red sunsets resulting from preferential scattering angle as a function of wavelength for white light by molecules in the earth's atmosphere.
1899	Marie Paul Auguste Charles Fabry (1867–1945) and Charles Fabry and Alfred Pérot (1863–1925)	Description of the Fabry–Perot interferometer, enabling high-resolution observation of spectral features.
1900	Max Karl Ernst Ludwig Planck (1858–1947)	Successful explanation of the spectrum of radiation emitted from a heated black body. Planck introduced a universal constant in his proportionality equation as the “quantum of action,” now known as Planck's constant. As a consequence the energy of an oscillator is the sum of small discrete units, each of which has a value that is proportional to the respective oscillation frequency.
1902	Woldemar Voigt (1850–1919)	Discovery of magnetic birefringence, or magnetic double refraction. The Voigt effect has several similarities to the Faraday effect.
1905	Albert Einstein (1879–1955)	Explanation of the photoelectric effect based on the assumption that light is quantized, these electromagnetic energy quanta become known as photons.
1908	Gustav Mie (1869–1957)	Presented a description of light scattering from particles that are not small compared to the wavelength of light, taking account of particle shape and the difference in refractive index between the particles and the supporting medium. This stands in contrast to Rayleigh scattering (John William Strutt, the 3rd Baron Rayleigh [1842–1919]), where the scattering dimensions are smaller than the wavelength.
1908	Walter Ritz (1878–1909)	Announcement of the combination principle for computing the frequencies of spectral lines.
1908	Louis Carl Heinrich Friedrich Paschen (1865–1947)	Experimental verification of the existence of a spectral series of hydrogen in the near infrared predicted by the Rydberg–Ritz relation.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1910–1912	Victor Franz Hess (1883–1964) and Werner Kol Hoerster (1887–1945)	Discovery of cosmic rays. Victor Franz Hess was awarded the Nobel Prize in Physics jointly with Carl David Anderson (1905–1991) in 1936.
1913	Neils Henrik David Bohr (1885–1962)	Atom model in which the electrons were presumed to occupy stable orbits demarcated by well-defined energy levels. This theory underwrites the quantum aspect of the absorption and emission of light by an atom resulting from the acceleration of an electron moving from one orbit to another orbit of different energy. This also provides an explanation of the absorption and emission at particular frequencies that are characteristic for that particular atomic energy configuration, depending on the element in question.
1915	William David Coolidge (1873–1975)	Patent on a method for creating tungsten electric lamp filaments.
1916	Albert Einstein (1879–1955)	Proposed stimulated emission of light process, complementing the standard absorption and spontaneous emission.
1919	Sir Arthur Stanley Eddington (1882–1944)	Observation of the solar eclipse on May 29 at Príncipe Island off the west coast of Africa. it was Eddington's intention to determining the apparent position of stars that are visible close to the sun's disk. From this he managed to conclude that the path of light from these stars is bent by the sun's gravitational field, conforming to the predictions of the theory of general relativity by Albert Einstein (1879–1955).
1926	Albert Abraham Michelson (1852–1931)	Determination of the speed of light by means of a rotating mirror with a light path from the observatory at Mount Wilson, Pasadena, California, spanning a distance of 35 km to a reflector on Mount San Antonio. Average value $c = 299,796,000 \text{ m.s}^{-1}$.
1927	Paul Adrien Maurice Dirac (1902–1984)	Presentation of electromagnetic radiation field in quantized form.
1928	Sir Chandrashekhara Venkata Râman (1888–1970)	Inelastic scattering of light from liquids, weak radiance line shifts. The effect arises from the scattering of light by vibrating molecules and is known as Raman scattering.
1932	Roy James Kennedy (1897–1973) and Edward Moulton Thorndike (1905–)	Experimentally attempted to detect the aether drift with a very stable and refined form of interferometer having arms of unequal length. Both the length and the time transformations of the special theory of relativity had to be used to account for the null result.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1932	Peter Joseph William Debye (1884–1966) with Francis Weston Sears (1898–1975) next to René Lucas (1898–1990) and Pierre Biquard (1901–1992)	Description of diffraction of electromagnetic radiation by ultrasonic waves; beginning of acousto-optics.
1932	Edwin Herbert Land (1909–1991)	Invention of the “polaroid” polarizing film.
1934	Frits Zernicke (1888–1966)	Description of the phase-contrast microscope.
1939	Walter H. Geffcken (1904–1995)	Description of the transmission interference filter.
1941	W. Canton Anderson ()	Measured the speed of light using a Kerr cell used to modulate a light beam passing through a Michelson interferometer. Obtained the value $c = 299,776,000 \text{ m.s}^{-1}$. Note that the current accepted and verified speed of light in vacuum is $299\,792\,458 \text{ m.s}^{-1}$.
1947	Willis Eugene Lamb, Jr. (1913–2008) and Robert E. Retherford (1882–1939)	During the course of spectral measurements of the fine structure of hydrogen in the microwave region of electromagnetic radiation, made the observation of a small displacement (the “Lamb shift”) of an energy level from its theoretical position as predicted by Dirac’s quantum theory of the electron (Paul Adrien Maurice Dirac [1902–1984]). Lamb was awarded the Nobel Prize in Physics jointly with Polykarp Kusch (1911–1993) in 1955.
1948	Dennis Gabor (1900–1979)	Description of the principles of wave front reconstruction, evolving into holography.
1954	Charles Hard Townes (1915–2015), James Power Gordon (1928–2013) and Herbert J. Zieger (1925–2011)	Publication: “Molecular microwave oscillator and new hyperfine structures in the microwave spectrum of NH_3 ,” describing the maser at Columbia University operating on ammonia producing coherent microwave radiation: MASER. Charles Hard received the Nobel Prize in Physics in 1964.
1958	Arthur Leonard Schawlow (1921–1999) and Charles Hard Townes (1915–2015)	Publication of “Infrared and Optical Masers” in which the maser principle were proposed to be extended into the visible region of the electromagnetic spectrum, creating the “laser” concept.
1958	Gordon Gould (1920–2005)	Arguably one of the first people to design, build, and operate a laser.
1960	Theodore Harold Maiman (1927–2007)	Described the first operational laser, built at the Hughes Research Laboratories, operating a rod of synthetic ruby as the medium: Ruby LASER.
1960	Ali Javan [Persian: جوان علی] (1926–)	Construction and operation of the first helium-neon laser.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1961	Peter Alden Franken (1928–1999), Arthur E. Hill (–2014), C. W. Peters () and Gabriel Weinreich (1930?–)	Demonstrated harmonic generation, specifically second harmonic, from laser light by transmission of the ruby laser pulse through a quartz crystal.
1961	Ali Javan (1926–), William Ralph Bennett (1930–2008), and Donald R. Harriott (1928–2007)	First gas laser at the Bell Laboratories. Lasing medium was a helium and neon mixture, emitting in the near infrared, the line with highest radiance at a wavelength of 1153 nm.
1962	Marshall I. Nathan, Robert H. Rediker, Robert N. Hall, W. Keyes, Ted M. Quist, Nick Holonyak (1928–) and S. F. Bevacqua	Five groups describing the observation of stimulated emission from gallium arsenide semiconductor diodes: inception of the diode laser. Based on the pioneering work of Captain Henry Joseph Round (1881–1966) in 1907 and Rubin Braunstein () in 1955.
1963	Chandra Kumar Naranbhai Patel (1938–)	The first carbon dioxide laser, Bell Laboratories.
1964	William B. Bridges (1934–)	First ion laser built at Hughes Research Laboratories.
1964	Jerome V. V. Kasper () and George Claude Pimentel (1922–1989)	Photodissociation mechanism of action description for the Iodine laser. The laser operated at a wavelength of 1315 nm at the University of California, Berkeley. The population inversion in atomic iodine was induced by the photodissociation of either CH_3I or CF_3I .
1966	Peter P. Sorokin (1931–) and John R. Lankard ()	First organic dye laser
1967–1969	S. L. McCall () and E. L. Hahn ()	Described studies of the propagation of very short optical pulses through a medium consisting of resonant two level atoms, developing in the process the criteria to be satisfied by the shape of the pulse so that it would propagate as an optical soliton (the area theorem) and describing the propagation mechanism of self-induced transparency (SIT).
1971	John M. J. Madey (1943–)	Publication: “Stimulated emission of bremsstrahlung in a periodic magnetic field,” Madey describes the principles of the free electron laser.
1976	John M. J. Madey (1943–)	Stanford University group operates the first free electron laser (FEL).
1985	Dennis L. Matthews ()	X-ray laser at the Lawrence Livermore National Laboratory, operating at 20 nm emission wavelength band.
1990		The Hubble space telescope is positioned in a low orbit around Earth on April 25, 1990.

Quantum

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1850	Sir William Rowan Hamilton (1805–1865)	Reformulation of Newtonian mechanics: Hamilton mechanics. Hamilton mechanics can be considered an essential building block to the development of quantum mechanics. Sir William Hamilton introduced the principles leading to the formulation of the Hamiltonian operator used in quantum mechanics, defining the total energy of a system.
1916	Niels Henrik David Bohr (1885–1962)	Atomic structure and quantum theory.
1922	Erwin Rudolf Josef Alexander Schrödinger (1887–1961) and Hermann Klaus Hugo Weyl (1885–1955)	Introduction of the quantum mechanical principles, which formed the basis for several imaging techniques.
1924	Louis-Victor-Pierre-Raymond, 7th duc de Broglie (1892–1987)	Introduction of the wave phenomenon with respect to all object in motion. Matter wave, propagating with the de Broglie wavelength.
1927	Wolfgang Ernst Pauli (1900–1958) Ralph Kronig (1904–1995), George Eugene Uhlenbeck (1900–1988), Samuel Abraham Goudsmit (1902–1978), and Paul Adrien Maurice Dirac (1902–1984)	Introduction of the electron spin concept and a broad range of relativistic quantum mechanical principles. This formed the foundation for the development of the NMR imaging system: nuclear magnetic resonance (MRI).
1937	John Archibald Wheeler (1911–2008)	Theoretical physics and relativity. Corrections to the Bohr (Niels Bohr [1885–1962]) liquid drop model.
1948	Richard Phillips Feynman (1918–1988)	Introduction of the Feynman diagrams.
1957	Rudolf Ludwig Mössbauer (1929–2011)	Discovery of atomic recoilless nuclear energy interaction under gamma radiation resulting in resonance fluorescence: Mössbauer effect.
1964	Charles Hard Townes (1915–2015), Nikolay Gennadiyevich Basov [Никола́й Генна́диевич Ба́сов] (1922–2001), and Aleksandr Mikhailovich Prokhorov [Алекса́ндр Миха́йлович Про́хоров] (1916–2002)	Quantum electronics.

Solid-state

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
"Ancient man"		Realization that the following chemical compounds were pure; what we currently consider as elements: gold (8000 BC), silver (<5000 BC), iron (<5000 BC), copper (9000 BC), mercury (<2000 BC), tin (~3500 BC), carbon (3750 BC), and sulfur (2000 BC).
450 BC	Leucippus (fifth century BC)	Argued that the universe consists as a structure of atoms and voids.
430 BC	Democritus (of Greece) (460 BC–370 BC)	Proclamation that the atom is the smallest and simplest unit of all matter. All matter is composed of atoms. The first rudimentary introduction of the elementary build block but with no scientific support. Greek word "atomos" (ἄτομος), meaning indivisible.
350 BC	Aristotle (384 BC–322 BC)	Declaration of only four (4) elements defining the existence on earth: fire, water, air, and earth. Matter only has the following properties: wet, dry, hot, or cold.
300	Alchemists:	Based on the philosophy of Aristotle the alchemists believed that "regular" metals could be converted into precious metal, specifically gold; wishful thinking... The item required to perform this conversion was referred to as the elusive "philosopher's stone."
1615	Jean Beguin (1550–1620)	First diagram expression for a chemical reaction in a notation that we still adhere to today.
1661	Robert Boyle (1627–1691)	First "modern chemist." End of the era of the Alchemists (perpetuated for 2000 years), partially based on the book by Robert Boyle <i>The Sceptical Chymist</i> .
1669	Henning Brand (1630–1710)	Documented observation that phosphorus is an element.
ca. 1670	Sir Isaac Newton (1643–1727)	Sir Isaac Newton was one of the prominent proponents and advocates of the atom theory.
1757	William Cullen (1710–1790)	Introduction of the first formula for a chemical reaction.
1774	Antoine Lavoisier (1743–1794)	Discovery of oxygen; and the chemical process of oxidation.
1785	Charles Augustin de Coulomb (1736–1806)	Treatise on electricity: <i>Premier Mémoire sur l'Électricité et le Magnétisme</i> . The unit of electric charge is named after him posthumously. The free electric charge is the electron, which was neither fully understood, nor described. The electron does form the basis for strong chemical connections, based on ion formation.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1789	William Higgins (1763–1825)	First use of the term molecule describing a chemical compound consisting of multiple atoms. The word molecule can be traced back to 1678. The expression and concept of the molecule has ties to Rene Descartes (1596–1650) and Robert Boyle (1627–1991).
ca. 1800	John Dalton (1766–1844)	Introduction of the “law of multiple proportions” describing the atomic concept based on chemical reactions taking place in ratios of small whole numbers.
1806	Sir Humphry Davy, 1st Baronet (1778–1829)	Discovery of several alkali next to alkaline earth metals, as well as contributions to the description and discovery of the elemental nature of the elements chlorine and iodine.
1804	Christian Samuel Weiss (1780–1856)	Description of crystalline structure as a configuration of attractions and repulsions, based on the work of René Just Haüy (1743–1822).
1807	Thomas Young (1773–1829)	Formal introduction of the Young’s modulus for elastic deformation, tying strain to stress, based on the work by Leonard Euler (1707–1783).
1820	Pierre Louis Dulong (1785–1838) and Alexis-Thérèse Petit (1791–1820)	Dulong and Petit law of specific heats; coupled oscillators.
1820	Claude Louis Marie Henri Navier (1785–1836)	Efforts on developing mathematical models describing molecular concepts for elasticity of three-dimensional isotropic bodies, expressed in <i>Lois de l’équilibre et du mouvement des corps solides</i> .
1826	Franz Ernst Neumann (1798–1895)	Mathematical description of the “crystalline structure.” Franz Neumann additionally described the heat exchange and specific heat concept based on the work of Alexis-Thérèse Petit and Pierre Louis Dulong (Dulong–Petit law). This was published almost 30 years later as the Kopp–Neumann rule, by his student Hermann Franz Moritz Kopp (1817–1892). Student of Christian Samuel Weiss (1780–1856).
1827	Augustin-Louis Cauchy (1789–1857)	Theory of linear elasticity: Cauchy relations.
1850	Sir William Rowan Hamilton (1805–1865)	Sir Hamilton is most known for his reformulation of Newtonian mechanics: Hamilton mechanics. Hamilton mechanics can be considered an essential building block to the development of quantum mechanics. Sir William Hamilton introduced the principles leading to the formulation of the Hamiltonian operator used in quantum mechanics, defining the total energy of a system.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1850	Auguste Bravais (1811–1863)	Uncovered lattice structure: Bravais lattice.
1850	George Boole (1815–1864)	Known for the Boolean algebra and logic. The work of George Boole inspired Claude Shannon (1916–2001).
1852	Wilhelm Eduard Weber (1804–1891)	Molecular model for magnetism, based on the “molecular rotation,” which allows alignment of the electrical eddy currents to form a magnetic solid with a defined North and South pole under application of an external magnetic field. Assisted by the work of Sir James Alfred Ewing (1855–1935).
1853	Gustav Heinrich Wiedemann (1826–1899) and Rudolf Franz (1827–1902)	Relationship between electrical conductivity and thermal conductivity for a solid medium.
1857	Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Introduction of chemical thermodynamics concepts and definitions and electrodynamics.
1860	Georg Friedrich Bernhard Riemann (1826–1866)	The work of Bernhard Riemann was instrumental in the development of the development of the theory of general relativity and the supporting mathematical evaluation.
1864	Augustus Matthiessen (1831–1870)	Description of the specific conductivity of materials as a function of temperature and impurities in the solid medium.
1865	James Clerk Maxwell (1831–1879)	Electromagnetic theory.
1870	Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Unofficial introduction to the mechanism of action for nuclear fusion.
1873	Josiah Willard Gibbs (1839–1903)	Chemical potential, a energy constituent within the Gibbs free energy. Thermodynamic concept describing the energy that can be released or absorbed during a chemical reaction.
1879	William Crookes (1832–1919)	Cathode rays and realization that single charged particles must be involved.
1879	Edwin Hall (1855–1938)	Description of the “Hall effect”: the expression of a transverse force on the electric charges within a conductor carrying a current while exposed to an external magnetic field: polarization resulting in a measurable electric potential between the lateral sides of the conductor.
1880	Pierre Curie (1859–1906) and Jacques Curie (1856–1941)	Discovery of the generation of electricity by mechanical manipulation of crystals: piezoelectric concept.
1884	Ludwig Minnigerode (1773–1839)	Recognition of at least 32 possible crystal classes, based on his mentor’s work: Franz Ernst Neumann (1798–1895).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1885	Eugene Goldstein (1850–1930)	Principle discovery of the proton, however not recognized as such.
1888	Heinrich Friedrich Weber (1843–1912)	Discovery that the emitted wavelength band from a heated body changed the peak wavelength location as a function of the measured temperature. This paved the way for the radiation formula released by Max Planck (1858–1947), it also provided the entry into quantum theory.
1890	Jules Henri Poincaré (1854–1912)	Introduction of methods and means for deriving accurate topographical data. Some of the work of Poincaré revolved around defining the geometry of the universe. Poincaré also contributed to fluid dynamic modeling in addition to the description of celestial motion.
1896	Wilhelm Conrad Röntgen (1845–1923)	Discovery of X-ray radiation.
1896	Henri Becquerel (1852–1908)	Emission of “Becquerel rays” from uranium salts, later identified as alpha particles. Becquerel already recognized that this emission was different from X-ray since it was deflected by means of an applied external magnetic field. Conceptual introduction to the field of radioactivity.
1897	Joseph John Thomson (1856–1940)	Discovery of the electron concept; using William Crookes’s vacuum tube. The electron itself was at this point not identified.
1897	Joseph John Thomson (1856 – 1940)	Introduction of the concept “ionic bond,” also referred to as polar bond.
1897	Marie Skłodowska-Curie (1867–1934)	Discovery of radioactive isotopes. Marie Curie introduced the term “radioactivity.”
1899	Paul Karl Ludwig Drude (1863–1906)	Introduction of the “free electron gas” for conduction in metals, based on his work under Woldemar Voigt (1850–1919). Additional work by Paul Drude was in optics, specifically the description of light and interaction with (transparent) object base on the theories of James Clerk Maxwell (1831–1879).
1899	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Emission of alpha particle.
1900	Samuel Giuseppe Vito Volterra (1860–1946)	Description and formulation of cylindrical waves. Volterra became involved in the biological cause and effect, respectively predator–prey, aspects, pioneering the field of mathematical biology.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1900	David Hilbert (1862–1943)	Hilbert space: vector space designed to accommodate an infinite number of dimensions, with respect to the three-dimensional Euclidean space. The Hilbert spatial interpretation forms an indispensable tool in solving for partial differential equations, as well as pertaining to quantum mechanics, and Fourier analysis. In Fourier analysis this applies to applications in signal processing and heat transfer. Hilbert Space is an ergodic theory, which provides the mathematical foundations of certain thermodynamics topics.
1900	Max Karl Ernst Ludwig Planck (1858–1947) and James Clerk Maxwell (1831–1879)	Formal description of the photon and the energy associated with the electromagnetic wave. Introduction of Planck's radiation law.
1903	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Discovery of the nuclear decay half-life.
1903	Marie Skłodowska-Curie (1867–1934) and Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Quantification of nuclear decay.
1905	Albert Einstein (1879–1955)	Energy–mass equivalence hypothesis introduced. Einstein also published his theoretical interpretation of the movements of object, specifically approaching the speed of light in his special theory of relativity and general theory of relativity. In 1917 he published his predictions on stimulated emission and hence the preliminary description of the operations of a LASER. Additional mathematical work eludes to quantum theoretical approach.
1906	Dmitri Ivanovich Mendeleev (1834–1907)	Periodic Table of Elements.
1907	Pierre-Ernest Weiss (1865–1940) and Paul Langevin (1872–1946)	Refinement of the local magnetic field in ferromagnetic materials, the early work by Wilhelm Eduard Weber (1804–1891).
1908	Johannes Geiger (1822–1945) and Ernest Rutherford (1871–1937)	Development of the Geiger counter, used to measure radioactive radiation.
1909	Francis Aston (1877–1945)	Mass spectrometer mass separation of closely separated isotopes. Highly sensitive mass spectrometer design.
1909	Robert Andrews Millikan (1868–1953)	Measurement of the mass of the electron.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1910	Amalie Emma Noether (1882–1935)	Master of abstract algebra. Amalie Noether also introduced the concept of conservation laws based on the symmetry in nature and physics and engineering.
1910	Hermann Klaus Hugo (Peter) Weyl (1885–1955)	Weyl studied under David Hilbert (1862–1943) and was also close to Amalie Emma Noether (1882–1935). Hermann Weyl uncovered a gauge invariance and with his interpretation of Riemann surfaces his teachings form the basis of many aspects supporting the theoretical explanation in modern physics concepts. Weyl also contributed to the efforts of Erwin Schrödinger (1887–1961).
1911	Heike Kamerlingh Onnes (1853–1926)	Discovery of superconductivity. Building on the resistance measurements at low temperatures by Sir James Dewar (1842–1923) and J. Andrew Fleming (1846?–1928?) in 1892.
1911	Ernest Rutherford (1871–1937), 1st Baron Rutherford of Nelson, Lord Rutherford of Nelson	Rutherford scattering on nuclear level, indication of the existence of the proton. The proton itself was not mentioned until 1932, this time again by Ernest Rutherford.
1911	Niels Henrik David Bohr (1885–1962)	Elaboration on the “electron gas model” introduced by Paul Karl Ludwig Drude (1863–1906) in 1899.
1912	Max Theodor Felix von Laue (1879–1960)	Established wave nature of X-rays represented by an interference pattern by means of crystal diffraction. Max von Laue received the Nobel Prize in Physics for his discovery in 1914.
1912	Max Born (1882–1970)	Description of the vibration mechanics in (crystalline) lattice structures, providing a fundamental theoretical formulation of the specific heat concept introduced by Albert Einstein (1879–1955) in 1911.
1913	Niels Henrik David Bohr (1885–1962)	Bohr atomic model.
1913	Frederick Soddy (1877–1956)	Formal introduction of the isotope concept.
1913	William Lawrence Bragg (1890–1971) and William Henry Bragg (1862–1942)	Bragg X-ray diffraction for crystal lattice structure: Bragg law. This may often be considered the official beginning of the field for condensed matter physics, respectively, solid-state physics.
1913	Gilbert Newton Lewis (1875–1946)	Introduction of the free electron metallic bond; based on the work by Paul Karl Ludwig Drude (1863–1906).
1914	Niels Henrik David Bohr (1885–1962)	Description of the atomic energy layer model; hydrogen (Bohr atomic model).
1915	Ernest Marsden (1889–1970)	Artificial transmutation, associated with radon enclosed by vacuum.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1916	Niels Henrik David Bohr (1885–1962)	Atomic structure and quantum theory.
1916	Gilbert Newton Lewis (1875–1946)	Description of the shell filling for atomic electrons, and the related covalent bond and the concept of valence electrons.
1917	Ernest Rutherford, 1st Baron Rutherford of Nelson (1871–1937)	Discovery of the proton.
1918	Paul Scherrer (1890–1969)	X-ray diffraction, crystal structure. Nuclear energy development. Established the CERN institute in Switzerland as one of the founders. Directed the construction of the first cyclotron in 1940.
1919	Ernest Rutherford (1871–1937)	Artificial transmutation, hydrogen formation resulting from collisions of alpha particles with nitrogen, also generating oxygen and gamma rays.
1921	Willem Hendrik Keesom (1876–1956)	Keesom theory for degenerate gas. Description of dipole–dipole interaction. William Keesom provided a description of the specific heat at low temperatures. Keesom also managed to freeze helium in 1926.
1921	Alfred Landé (1888–1976)	Mathematician who introduced the Landau factor for an electron with both self-rotation spin and orbital angular momentum.
1922	Erwin Rudolf Josef Alexander Schrödinger (1887–1961) and Hermann Klaus Hugo Weyl (1885–1955)	Introduction of the quantum mechanical principles, supporting the understanding of high-energy physics phenomena such as the atomic structure.
1923	John von Neumann (1903–1957) [original name: Neumann Janos Lajos]	Introduced finite element methodology (also known as Monte Carlo simulation), integration of random number generation. He was also instrumental in the design of thermonuclear bombs as well as significantly advanced the field of hydrodynamics.
1923	Arthur Holly Compton (1892–1962)	Description of the deflection of photons by a charge unit, generally an electron, potentially the nucleus: Compton effect.
1924	Niels Henrik David Bohr (1885–1962)	Introduction of the term: “element”. This idea was formed based on Wolfgang Pauli’s (1900–1958) exclusion principle. The element concept has been around for millennia.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1924	Satyendra Nath Bose (1894–1974) [সত্যেন্দ্র নাথ বসু] and Albert Einstein (1879–1955)	Introduction of the Bose–Einstein statistics: one of two potential manners of energy occupation for a collection of noninteracting indistinguishable particles with respect to a set of available discrete energy states, this applies to thermodynamic equilibrium only. At extreme low temperatures these energy levels for bosons can result in a joining of states: condensation, the Bose–Einstein condensate.
1924	Sir John Edward Lennard-Jones (1894–1954)	Definition of the attraction between two neutral molecules or atoms: Lennard Jones potential.
1924	Louis-Victor-Pierre-Raymond, 7th duc de Broglie (1892–1987)	Introduction of the wave phenomenon with respect to all object in motion. Matter wave, propagating with the de Broglie wavelength.
1925	Werner Heisenberg (1901–1976)	Introduction of quantum mechanics, specifically in matrix formulation. Heisenberg also introduced the “uncertainty principle”; two parameters describing the same item or phenomenon cannot be known simultaneously with exact accuracy, such as momentum and position, but are inherently linked to each other with a product that yields the reduced-Planck-constant divided by two or greater.
1925	Wolfgang Ernst Pauli (1900–1958)	Pauli exclusion principle for atomic energy levels.
~1925		Recognition of the “Coulomb barrier” in nuclear collision, providing a “tunneling” effect for the release of alpha particles.
~1926	Paul Langevin (1872–1946)	Elaborate work on paramagnetism and diamagnetism with a significant contribution to the development of ultrasound detection based on the piezoelectrics effect discovery by Pierre Curie (1859–1906) and Jacques Curie (1856–1941) in 1888. Paul Langevin introduced the “Twin Paradox” concept with respect to Special Relativity introduced by Albert Einstein (1879–1955).
1926	Paul Dirac (1902–1984) and Enrico Fermi (1901–1954)	Fermi–Dirac statistics.
1926	1928: Paul Dirac (1902–1984); 1929 Dmitri Vladimirovich Skobeltsyn (1892–1990); 1932 Carl David Anderson (1905–1991)	Discovery of positron.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1926	Eugene Paul Wigner (1902–1995)	Series publications on the application of group theory in quantum mechanics. Eugene Wigner shared the Nobel Prize in Physics jointly with Maria Goeppert-Mayer (Göppert) and Johannes Hans Daniel Jensen (1907–1973) in 1963.
1926	Jean Baptiste Perrin (1870–1942)	Physical proof providing the existence of molecules.
1927	Werner Karl Heisenberg (1901–1976)	Quantum Uncertainty Principle.
1927	Paul Adrien Maurice Dirac (1902–1984)	Description of antimatter.
1927	Wolfgang Ernst Pauli (1900–1958) Ralph Kronig (1904–1995), George Eugene Uhlenbeck (1900–1988), Samuel Abraham Goudsmit (1902–1978), and Paul Adrien Maurice Dirac (1902–1984)	Introduction of the electron spin concept and a broad range of relativistic quantum mechanical principles. This formed the foundation for the development of the NMR imaging system: nuclear magnetic resonance (MRI).
1928	Arnold Johannes Wilhelm Sommerfeld (1868–1951)	Theory of metals: free electron model that obeys the Fermi–Dirac statistics; Paul Adrien Maurice Dirac (1902–1984) and Enrico Fermi (1901–1954).
1928	Johannes Geiger (1822–1945) and Walther Müller (1905–1979)	Introduction of an improved Geiger counter: the Geiger–Müller counter, using ionization of a confined gas.
1928	Sir Chandrasekhara Ventaka Raman (1888–1970)	Raman spectroscopy; indicating the energy levels in atoms and molecules.
1928	Felix Bloch (1905–1983)	Description of the migration process of electrons in an atomic lattice structure. The electron transport formed what Felix Bloch referred to as a wave process, now referenced as Bloch waves. The wave process (i.e., wavelength) directly corresponds to the periodic nature of the lattice structure, in particular for a crystal.
1930	Enrico Fermi (1901–1954)	Chemical potential for electrons: Fermi level, equivalent to the thermodynamic work required to add or remove an electron to the energy configuration of the body. This applies in particular to semiconductors and the working of p-type[and n-type-doped materials such as diodes and transistors.
1931	Linus Carl Pauling (1901–1994)	Description of the general and detailed nature of various types of chemical bonds.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1931	Wolfgang Ernst Pauli (1900–1958)	Theoretical introduction of the neutrino. The experimental verification of the existence of the neutrino was not until 1956 by Frederick Reines (1918–1998) and Clyde Cowan Jr. (1919–1974).
1931	Carl David Anderson (1905–1991)	Discovery of the positron, antiparticle for the electron. The “positron” was predicted by Paul Adrien Maurice Dirac (1902–1984) in 1929.
1932	Sir James Chadwick (1891–1974)	Discovery of the neutron. Student of Ernest Rutherford (1871–1937).
1934	Leo Szilard (1898–1964)	Recognition of nuclear decay chain reactions.
1934	Hideki Yukawa [湯川 秀樹], (1907–1981)	Introduction of mesons and the concept of antimatter.
1934	Ida Noddack (1896–1978)	Formal introduction of the concept of “fission,” however, not recognized by her peers at the time. The fission phenomenon was only recognized when announced by Enrico Fermi (1901–1954) later that year.
1934	Enrico Fermi (1901–1954)	Interaction of slow neutron with nuclei and the resulting decay into different elements, including aluminum and uranium.
1935	Enrico Fermi (1901–1954)	Developed Fermi–Dirac statistics, although independent from Paul Dirac (1902–1984) but simultaneously. The Fermi–Dirac statistics applies to fermions, while the counterpart that it does not include are referred to as bosons. Fermi worked on X-ray crystallography, as well as energy levels in semiconductor structures. The Fermi level concept for electrons in atomic energy approximating absolute zero ties directly in with the Pauli exclusion principle. Fermi worked with and studied under Max Born (1882–1970), Werner Heisenberg (1901–1976), Pascual Jordan (1902–1980), Paul Ehrenfest (1880–1933), Hendrik Lorentz (1853–1928), Samuel Goudsmit (1902–1978), Jan Tinbergen (1903–1994), and Albert Einstein (1879–1955). Fermi concluded that beta decay from the nucleus formed another energetic particle and determined it to be real and named it a neutrino.
1935	Paul Adrien Maurice Dirac (1902–1984)	Developed Fermi–Dirac statistics, although independent from Enrico Fermi (1901–1954) but simultaneously.
1935	Arthur Dempster (1886–1950)	Discovery of the lighter uranium isotope: Uranium-235.
1936	Otto Hahn (1879–1968) and Lise Meitner (1878–1968)	Neutron collision of uranium-induced decay examination.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1937	Carl David Anderson (1905–1991), Seth Henry Neddermeyer (1907–1988), Jabez Curry Street (1906–1989), and Edward C. Stevenson ()	Confirmation of the existence of the meson, and muon.
1938	Niels Henrik David Bohr (1885–1962) and John Archibald Wheeler (1911–2008)	Formal description of the nuclear fission process.
1939	Jerome M. B. Kellogg (1905–)	Discovery of a finite quadruple moment for the deuteron, requiring a noncentral (tensor) nuclear force configuration.
1940	Otto Robert Frisch (1904–1979)	Development of the detonation mechanism for the first atomic bomb
1940+	Julius Robert Oppenheimer (1904–1967)	Manhattan project: fission reaction. Prominent members: Arthur Compton (1892–1962), Enrico Fermi (1901–1954), Eugene Wigner (1902–1995), and dozens more.
1947	Charles Kittel (1916–)	Elaborate theoretical work on solid-state physics, respectively: condensed matter physics.
1947	George Dixon Rochester (1908–2001), Clifford Charles Butler (1922–1999)	Discovery of the subatomic particle: the “kaon,” k-meson. Introduction of the “strangeness” concept for quarks, although the quark concept had not been introduced. In the elementary particle phenomenology the kaon is a bound state of an up- or down quark with a strange quark (antiquark).
1947	Maria Goeppert-Mayer (Göppert) (1906–1972)	Theoretical concept development for the understanding of nuclear forces, based on a shell model, similar to the atomic electron model.
1947	William Webster Hansen (1909–1949)	Linear accelerator installation at Stanford University, California.
1950	Maria Goeppert-Mayer (Göppert) (1906–1972)	Introduction of the nuclear shell model of atomic nuclei.
ca. 1952	Ludwig von Helmholtz (1821–1894), Lyman Strong Spitzer, Jr. (1914–1997), and Ronald Richter (1909–1991) and Edward Teller (1908–2003)	Nuclear fusion investigation and start of experimentation. The process was in principle described by Hermann Ludwig Ferdinand von Helmholtz (1821–1894), but is continuously in action at the sun’s surface.
1955	Obninsk Nuclear Power Station, Russia	First nuclear power station for energy generation.
1956	Frederick Reines (1918–1998) and Clyde Lorrain Cowan Jr. (1919–1974)	Experimental confirmation of the neutrino introduced in 1931 by Wolfgang Pauli (1900–1958).

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1957	John Bardeen (1908–1991), John Robert Schrieffer (1931–) and Leon N. Cooper (1930–)	Bardeen–Cooper–Schrieffer theory of superconductivity.
1958	Stanley Mandelstam (1928–)	Introduction of Mandelstam variables associated with the concept of “crossing symmetry,” defining numerical quantities which encode the energy, momentum, and scattering angles of particles in a deflection process described in a Lorentz-invariant fashion.
1958	Lev Davidovich Landau [Russian: Лёв Давидович Ландау] (1908–1968), Arkady Beynusovich Migdal [Russian: Аркадий Бейнусович (Бенедиктович) Мигдал] (1911–1991)	Theory of interacting electrons, specifically with respect to solids; condensed matter physics.
1961	Murray Gell-Mann (1929–)	Description of elementary particles, eightfold way of defining “strangeness” for the quark. Formal introduction of the elementary particle “quark” concept, the building blocks for protons and neutrons. The “quark” name is based on an expression in the book <i>Finnegans Wake</i> by James Joyce.
1964	Charles Hard Townes (1915–2015), Nikolay Gennadiyevich Basov [Николай Геннадиевич Басов] (1922–2001) and Aleksandr Mikhailovich Prokhorov [Александр Михайлович Прόхоров] (1916–2002)	Quantum electronics.
1970	Sheldon Lee Glashow (1932–), John Iliopoulos (1940–), and Luciano Maiani (1941–)	Introduction of the charm quark.
1974	Burton Richter (1931–) and Samuel Chao Chung Ting [Chinese: 丁肇中] (1936–)	Description of charm for the quark.
1975	Martin Lewis Perl (1927–2014)	Discovery of the tau lepton.
1977	Leon Max Ledderman (1922–)	Discovery of the “beauty” and “bottom” designation for quarks.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1978		Discovery of the “gluon” with the assistance of the PLUTO, the first electromagnetic superconductive solenoid located in Hamburg, Germany.
1983	Collider Detector at Fermilab	World’s first and at the time highest-energy particle accelerator, colliding antiprotons and protons propelled to center-of-mass energy reaching 2 TeV.
1986	Karl Alexander Müller (1927–) and Johannes Georg Bednorz (1950–)	High-temperature superconductivity.
1991	Sumio Iijima [飯島 澄男] (1939–)	Discovery of carbon nanotube.
1992	Kenneth Kin Man Kwong ()	Introduction of “functional MRI.” In 2013 the sugar consumption was measured in cancer cells with respect to normal cells for diagnostic verification.
1995	Wolfgang Ketterle (1957–), Eric Allin Cornell (1961–), and Carl Edwin Wieman (1951–)	Experimental verification of Bose–Einstein condensation.
1997	Sir Konstantin Sergeevich Novoselov (1974–) and Sir Andre Konstantin Geim (1958–)	Introduction of nanoscience; in particular the properties of graphene.

Thermodynamics

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
3300 BC–1000 BC	Bronze Age	Smelting and forging of soft metals using low heat: copper, tin, and gold. This age also introduces the written documentation.
1000 BC–700 AD	Iron Age	Higher heat requirements and more detailed tool manufacturing, introducing scientific and engineering challenges. Historical tracking of processes and developments and philosophies. Introduction of complicated mechanisms and requiring detailed analytical thinking.
500 BC	Heraclitus of Ephesus [Heraclitus: Ἡράκλειτος] (535 BC–475 BC)	Introduction of the concept of “flux”; referring to the flow of energy as well as media. One of the first reference to basic thermodynamic principles.
350 BC	Aristotle (384 BC–322 BC)	The word “energy” has the Greek origin “ <i>enérgeia</i> ” [Greek: ἐνέργεια], which was documented by Aristotle, “ <i>enérgeia</i> ” does not translation verbatim into English, the meaning resembles: “performing work.”

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
40 BC	Marcus Vitruvius Pollio [Vitruvius] (ca. 80 BC–10 BC)	Architectural designs that harness the solar energy.
62	Hero of Alexandria [ῥων ὁ Ἀλεξανδρεὺς], (10–70)	Mathematician, physicist, and mechanical engineer who also taught pneumatics. A set of two books, <i>The Pneumatica</i> , describes mechanical devices worked by air, steam, or water pressure. Also known as Heron of Alexandria. He invented a steam-powered engine called the “Æolipile,” relying on the heat exchange and mechanical conversion; fundamental thermodynamic concepts in practical application.
1500	Leonardo da Vinci (1452–1519)	The preverbal “Renaissance man,” involved in all aspects of cultural evolution, science, engineering, politics, and art.
1543	Nicolaus Copernicus (1473–1543); Alias of Niclas Koppernigk	Introduction of the heliocentric model for the earth, sun, and other planets. This follows the statement by the astronomer from Greece: Aristarchus of Samos (ca. 310–ca. 230 BC), made more than 1700 years prior. The scientific observations made by Copernicus were validated by Tycho Brahe (1546–1601) and Johannes Kepler (1571–1630).
1590	Francis Bacon, 1st Viscount of St. Alban (1561–1626)	Statement referring to motion being the essence of heat.
ca. 1600	William Gilbert (1544–1603)	
ca. 1600	Galileo Galilei (1564–1642)	Using a “thermoscope” Galileo Galilei was able to derive that fact that energy is exchanges during the flow of air and as such assign a scale of “heat” to the sensation: hotness vs. coldness. This principle can be traced back to Hero of Alexandria (10–70).
1614	René Descartes (1596–1650)	Introduction to vortex motion. Introduction of the concept of general corpuscular motion, extending from small (maybe referring to the undefined atom), to planetary orbits.
1660	Robert Boyle (1627–1691)	Gas laws, definition of the behavior or gases and phenomenological thermodynamic observations.
1673	Christiaan Huygens (1629–1695)	Construction of a “combustion engine” powered by gun powder. Huygens introduced several concept of mechanical engineering and described the mechanism of shock waves. The mathematical efforts of Christiaan Huygens in probability theory were far advanced and he collaborated with the mathematician Pierre de Fermat (1601–1665) from France.
1676		
1679	Denis Papin (1647–ca. 1712)	Pressure with inherent thermodynamic and mechanical impacts.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1680	Robert Hooke (1635–1703)	Force applied by a compressed spring and associated stored potential energy, which is exerted as kinetic energy upon release of the spring.
ca. 1687	Sir Isaac Newton (1643–1727)	
1687	Guillaume Amontons (1663–1705)	Innovations on hygrometer, thermometer, and barometer. Speculation about the existence of a low enough temperature where all atomic, respectively, molecular motion of a gas will cease, an “absolute zero” temperature, in reference to his experimentation with gases and based on the work of Joseph Louis Gay-Lussac (1778–1850). Additional work of Guillaume Amontons in 1699 describes friction in great detail, later verified by Charles-Augustin de Coulomb (1736–1806) in 1781.
1698	Thomas Savery (1650–1715)	Construction of the basic steam engine; using information obtained by Denis Papin (1647–c. 1712).
1712	Thomas Newcomen (1664–1729)	Construction of a “atmospheric” steam engine.
1724	Herman Boerhaave (1668–1738)	Description of phase changes for media and the associated exchange of energy.
1732	Anders Celsius (1701–1744)	Thermometer-scale calibration based on pure water phases.
1735	Daniel Gabriel Fahrenheit (1686–1736)	Temperature scale in Fahrenheit based on body temperature and saltwater phases.
1738	Daniel Bernoulli (1700–1782)	Hydrodynamics, vibrations, and kinetic theory. Definition of the fundamental frequency and higher harmonics, with supporting elaborate mathematical analysis (solutions to differential equations) in his publication <i>Hydrodynamica</i> .
1752	Benjamin Franklin (1706–1790)	Kite experiment and the documentation of “electric current” with associated electric energy content, most visible in the destructive power of lightning bolts.
1783	Antoine Laurent de Lavoisier (1743–1794)	Introduction of the “caloric theory,” “substance of heat.” Lavoisier constructed the first known calorimeter and measured the heat exchange resulting from a chemical reaction.
1757–1769	James Watt (1736–1819)	Modern steam engine design and operation with theoretical description of operation.
1762	Joseph Black (1728–1799)	Realization of the concept of latent heat; observation that ice is melting (phase change to liquid) without a change in temperature.

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1769	Nicolas-Joseph Cugnot (1725–1804)	First operational steam powered automobile, the predecessor to the internal combustion automobile.
1777	Carl Wilhelm Scheele (1742–1786)	Recognized heat transfer as the result of radiation (infrared light) to be a different exchange mechanism than convection and conduction.
1781	Charles-Augustin de Coulomb (1736–1806)	Definition of the electric field related to electric charge. The electric charge itself was still an elusive concept in those days.
1783	Antoine Laurent de Lavoisier (1743–1794)	Discovery of oxygen and the chemical impact.
1783	Joseph-Michel Montgolfier (1740–1810) and Jacques-Étienne Montgolfier (1745–1799)	Hot-air balloon; buoyancy.
1785	Jacques Alexandre César Charles (1746–1823)	Charles's law, expansion of gases.
1791	Pierre Prévost (1764–1823)	Experimentally verifies that all bodies radiate heat, regardless of their temperature. Precursor to Planck's law and Wien's law.
1798	Count Rumford (1753–1814), Benjamin Thompson	Quantitative analysis of the conversion of heat into work by means of his cannon-boring experimentation. This relates kinetic energy to heat and discredits the caloric theory.
1799	Sir Humphry Davy, 1st Baronet (1778–1829)	Experimental quantification of the conversion of work (friction) into heat using ice blocks that were rubbed on a surface and caused a phase change: liquification.
1802	Joseph Louis Gay-Lussac (1778–1850)	Ideal gas law; building on the work by Robert Boyle (1627–1691), more than a century earlier.
1824	Nicolas Léonard Sadi Carnot (1796–1832)	Thesis publication: "Reflections on the Motive Power of Fire," leading to the refrigerator for general public in 1842. Carnot introduced the cyclic process, which could be built into a cyclic machine, operating between two heat reservoirs, using the temperature of the reservoir as the parameter that influences the process, not necessarily the medium that is used in the system.
1827	Benoît Fourneyron (1802–1867)	First water turbine.
1841	Julius Robert von Mayer (1814–1878)	First attempt to define the laws of conservation, but was unsuccessful. Even though Julius Robert von Mayer lacked the mathematical skills to support his hypothesis he is still considered to be one of the founding fathers of thermodynamics.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1843	James Prescott Joule (1818–1889)	Quantitative experimental data collection and theoretical description of principal thermodynamic concepts.
1843–1848	James Prescott Joule (1818–1889)	Empirical verification of the first law of thermodynamics; equivalence of heat and work. This was later rewarded by assigning the heat quantity in unit Joule (J). Publication in 1851: “Remarks on the heat and the constitution of elastic fluids.”
1847	Hermann Ludwig Ferdinand von Helmholtz (1821–1894)	Formulation of the principles of conservation of energy.
1848	William Thomson, 1st Baron Kelvin (i.e., Lord Kelvin) (1824–1907)	Absolute temperature scale: Kelvin.
1850	Rudolf Julius Emanuel Clausius (1822–1888)	Recognition of two basic principles (later introduced by means of the first and second law of thermodynamics: energy is constant and entropy tends toward a maximum). Clausius introduced the parameter U , representing the internal energy. Publication of book: <i>On the Motive Power of Heat, and on the Laws Which Can Be Deduced From It for the Theory of Heat</i> . According to Josiah Willard Gibbs (1839–1903) Clausius was one of the founding fathers of thermodynamics in the principle manner we currently still use. Clausius introduced what is now regarded the second law of thermodynamics in 1865 (referred to by William John Macquorn Rankine (1820–1872) as the “thermodynamic function”), as part of any natural thermodynamic process, the sum of the entropies of the participating systems will increase.
1852	James Prescott Joule (1818–1889) and William Thomson, 1st Baron Kelvin {Lord Kelvin} (1824–1907)	Joule–Thomson effect: rapidly expanding gas leads to a reduction in the temperature of the gas, even offering the potential for a phase change to solid, or liquid. Sometimes also found as the Joule–Kelvin effect.
1859	William John Macquorn Rankine (1820–1872)	Publication of the book <i>A Manual of the Steam Engine and Other Prime Movers</i> , chapter titled “Principles of Thermodynamics,” introducing the concept of the “thermodynamic function” later recognized as entropy.
1860	James Clerk Maxwell (1831–1879)	Maxwell statistical distribution of atomic or molecular velocities for idealized gases, allowing for only brief elastic collisions. Published in 1867 as “On the dynamical theory of gases.”
1861	Augustin Mouchot (1825–1911)	Presentation of the use of solar energy as a source for personal energy consumption.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1862	Ludwig Eduard Boltzmann (1844–1906)	Refinements to the Maxwell distribution and associated entropy based on additional implementation of kinetic gas theory. This culminated in 1877 in the Maxwell–Boltzmann distribution.
1873	Josiah Willard Gibbs (1839–1903)	Thermodynamic concept describing the energy that can be released or absorbed during a chemical reaction. In 1875 Josiah Gibbs published his <i>On the Equilibrium of Heterogeneous Substances</i> , describing the thermodynamic aspects in general form describing chemical reaction and heterogeneous systems. This work included the chemical potential, a energy constituent within the Gibbs free energy.
1879	Joseph Stefan (1835–1893)	Determination that radiation has a quantity: radiance, which is proportional to the fourth power of the temperature of the system.
1893	Wilhelm Carl Werner Otto Fritz Franz Wien (1864–1928)	Black body emission: Wien's displacement law. The peak radiance emitted by a black body (spectral radiance) shifts to shorter wavelengths at higher temperatures.
1895	Wilhelm Röntgen (1845–1923)	Discovery of X-ray (Röntgen rays).
1897	Joseph John Thomson (1856–1940)	Discovery of the electron; using William Crookes's vacuum tube.
1900	Ludwig Eduard Boltzmann (1844–1906)	Boltzmann equation for statistical mechanics, introduced by Ludwig Boltzmann between 1872 and 1875, reformulated by Max Karl Ernst Ludwig Planck (1858–1947) defining the entropy of a system. For certain systems also addressed as the Gibbs entropy formula, after Josiah Willard Gibbs (1839–1903).
1906	Walther Hermann Nernst (1864–1941)	Third law of thermodynamics: "The entropy of a perfect crystal at absolute zero is exactly equal to zero," influenced by Johannes Diderik van der Waals (1837–1923).
1909	Constantin Carathéodory (1873–1950)	Theoretical discourse on thermodynamics, based on axiomatic principles, entirely mathematical in its format.
1912	Peter Joseph William Debye (1884–1966)	Increased accuracy in determination of heat capacity for a body by means of implementation of low frequency acoustics (low frequency phonons) in the analysis process.
1924	Sir John Edward Lennard-Jones (1894–1954)	Definition of the attraction between two neutral molecules or atoms: Lennard-Jones potential.

(Continued)

CHRONOLOGY	NOTEWORTHY PEOPLE	EVENTS AND DISCOVERIES
1924	Satyendra Nath Bose (1894–1974) [সত্যেন্দ্র নাথ বসু] and Albert Einstein (1879–1955)	Introduction of the Bose–Einstein statistics: one of two potential manners of energy occupation for a collection of noninteracting indistinguishable particles with respect to a set of available discrete energy states, this applies to thermodynamic equilibrium only. At extreme low temperatures, these energy levels for bosons can result in a joining of states: condensation, the Bose–Einstein condensate.
1931	Georges Jean Marie Darrieus (1888–1979)	Introduction of the wind turbine.
1931	Subramanyan Chandrasekhar (1910–1995)	Relativistic thermodynamics.
1940+	Julius Robert Oppenheimer (1904–1967)	Manhattan project: fission reaction. Prominent members: Arthur Compton (1892–1962), Enrico Fermi (1901–1954), Eugene Wigner (1902–1995), and dozens more.
1948	Claude Elwood Shannon (1916–2001)	Introduction of information theory, basis is in thermodynamic principles.
1972	Stephen Hawking (1942–) and Jacob Bekenstein (1947–2015)	Thermodynamics of black holes. Specific items of interest are the following. Jacob Bekenstein: the entropy of a black hole is proportional to its surface area; Stephen Hawking: black holes may radiate particle that may lead to the “evaporation” of the black hole.

Index of Names

Note: Names are arranged in chronological order by date of birth. Page numbers followed by f refer to images.

- Thales (624–546 BC), 396, 396f
Pythagoras (570–495 BC), 162, 162f
Socrates (469–399 BC), 103–104, 323, 323f
Hippocrates of Cos (460–377 BC), 85
Plato (427–347 BC), 103–104, 104f, 125, 510
Aristotle (384–322 BC), 78
Euclid (325–270 BC), 510
Archimedes (287–212 BC), 140
Hipparchus (190–125 BC), 155
Pollio, Marcus Vitruvius (80 BC–15 AD), 118–119, 119f
Ptolemaeus, Claudius (Ptolemy) (approximately 90–168 AD), 155, 155f, 322, 328, 510
Sahl, Ibn (Arabic: سهل ابن) (Abu Sa'd al-'Ala'ibn Sahl) (940–1000), 262, 262f, 322
Al-Birūnī (Abū al-Rayhān Muḥammad ibn Aḥmad al-Birūnī) (973–1048), 226
De Maricourt, Pierre (Pergrinus, Petri) (1220–1270), 33, 118
de Mondeville, Henri (1260–1320), 71
Da Vinci, Leonardo (1452–1519), 103, 119, 140, 350
Copernicus, Nicolaus (1473–1543), 162, 244, 328, 389
Vesalius, Andreas (1515–1564), 501–502, 502f
Fabricius, Georg (Goldschmidt) (1516–1571), 76, 76f
Gilbert, William, Sir (1544–1633), 501
Brahe, Tycho {Tyge Ottesen Brahe} (1546–1601), 328, 389, 413
Stevin, Simon (1548–1620), 350, 350f
Galilei, Galileo (1564–1642), 27, 150, 362, 389, 405, 433, 481, 502
Lipperhey, Hans (Lipperhey) (1570–1619), 389
Praetorius, Michael (original name: Michael Schultheiß) (1571–1621), 140, 140f
Metius, Jacobus (Jacobus Adriaanszoon) (1571–1624), 389
Kepler, Johannes (1571–1630), 100, 113, 264, 329, 413
Leeghwater, Jan Adriaanszoon (1575–1650), 347, 453
Van Helmont, Johannes (Jan) Baptista (1579–1644), 491, 491f
Janssen, Zacharias (1580–1640), 389
Rey, Jean (1583–1645), 405
Snel (“Snell”), Willebrord Snel van Royen (Snellius) (1591–1626), 262, 322–323, 322f, 492
Descartes, René (1596–1650), 245, 322, 350
Fermat, Pierre de (1601–1665), 18, 150
Roberval, Gilles Personne de (1602–1675), 244–245, 245f
Guericke, Otto von (1602–1682), 517–518, 518f, 559
Torricelli, Evangelista (1608–1647), 433, 433f, 481
Renaldini, Carlo {Rinaldini} (1615–1698), 227, 227f
Wallis, John (1616–1703), 530, 531f
Picard, Jean-Félix (1620–1682), 86, 127
Pascal, Blaise (1623–1662), 18f, 150, 350, 433, 481
Cassini, Giovanni Domenico (1625–1712), 350
Huygens, Christiaan (1629–1695), 6, 27, 79, 541
Van Leeuwenhoek, Antonie Philips (1632–1723), 491–492, 492f
Hooke, Robert (1635–1703), 541
Gregory, James (1638–1675), 384
Newton, Isaac, Sir (1642–1727), 16, 78, 147–148, 350, 362, 475, 541
Roemer {Rømer, also Römer}, Olaus (Ole) (1644–1710), 247, 247f, 405
Calley, John (1663–1725), 271
Stradivari, Antonio (1644–1737), 421
Papin, Denis (1647–1712), 4, 5f, 144, 271
Savery, Thomas (1650–1715), 5, 271, 271f
Sauveur, Joseph (1653–1716), 270, 270f
Cristofori, Bartolomeo (1655–1731), 85
Seignette, Pierre (1660–1719), 88
Newcomen, Thomas (1664–1729), 271
Gray, Stephen (1666–1736), 125
Riccati, Jacopo Francesco; Count (1676–1754), 239–240, 239f
Hales, Stephen (1677–1761), 434
Réaumur, René-Antoine Ferchault de (1683–1757), 219, 219f, 227
Taylor, Brook (1685–1731), 382, 382f, 384
Fahrenheit, Gabriel Daniel (1686–1736), 219, 227, 390, 405, 532
Van Musschenbroek, Petrus (1692–1761), 492, 492f
Voltaire, François-Marie d’Arouet (1694–1778), 515, 515f
Pitot, Henri (1695–1771), 93–94, 93f
Maclaurin, Colin (1698–1746), 109
Von Kleist, Ewald Jurgens (1700–1748), 520, 520f
Bernoulli, Daniel (1700–1782), 140–141, 301
Celsius, Anders (1701–1744), 219, 227, 390, 532
Franklin, Benjamin (1706–1790), 125, 501f
Euler, Leonhard (1707–1783), 32, 140
Gordon, Andrew (1712–1751), 359

- D'Alembert, Jean-Baptiste le Rond (1717–1783), 350
 Canton, John (1718–1772), 501f
 Lambert, Johann Heinrich (1728–1777), 350
 Black, Joseph (1728–1799), 400, 587
 IngenHousz, Jan (Ingen-Housz or Ingen Housz) (1730–1779), 80
 Wedgwood, Josiah (1730–1795), 545–546, 546f
 Priestley, Joseph (1733–1804), 81, 145–146, 146f
 Lavoisier, Antoine-Laurent de (1743–1794), 145
 Coulomb, Charles-Augustin de (1736–1806), 411
 Watt, James (1736–1819), 537–538, 538f
 Galvani, Luigi (1737–1789), 514
 Lagrange, (Joseph-Louis) Giuseppe Luigi comte de Lagrange (1737–1813), 110, 113, 350
 De Saussure, Horace-Bénédict (1740–1799), 327
 Scheele, Carl Wilhelm (1742–1786), 76, 278–279, 279f
 Volta, Alessandro Giuseppe Antonio Anastasio Gerolamo Umberto, Count (1745–1827), 514–515, 514f
 Venturi, Giovanni Battista (1746–1822), 499–500, 500f
 Bennet, Abraham (1749–1799), 501f
 Laplace, Pierre-Simon de, Marquis de Laplace (1749–1827), 113, 150, 301, 350, 572
 Van Marum, Martin (1750–1837), 559
 Prévost, Pierre (1751–1839), 145
 Legendre, Adrien-Marie (1752–1833), 113, 350
 Thomson, Benjamin, Sir (Count Rumford) (1753–1814), 250, 409, 409f
 Gregor, William (1761–1817), 425
 Chappe, Claude (1763–1805), 386
 Pfaff, Johann Friedrich (1765–1825), 44, 44f, 545
 Niépce, Joseph Nicéphore (1765–1833), 77
 Bonaparte, Napoléon (1769–1821), 514
 Seebeck, Thomas Johann (1770–1831), 292, 292f, 399
 Daguerre, Louis-Jacques-Mandé (1787–1851), 292
 Young, Thomas (1773–1829), 146–147, 541, 571–573, 571f
 Biot, Jean-Baptiste (1774–1862), 270
 Malus, Étienne Louis (1775–1812), 113
 Ampère, André Marie (1775–1836), 359
 Ritter, Johann Wilhelm (1776–1810), 243, 243f, 470
 Avogadro, Lorenzo Romano Amedeo Carlo (1776–1856), 41
 Gauss, Johann Carl Friedrich (German: Gauß) (1777–1855), 44, 545
 Poinot, Louis (1777–1859), 110, 110f
 Davy, Humphry (1778–1829), 324
 Poisson, Siméon Denis (1781–1840), 113–114, 113f
 Brewster, David (1781–1868), 88
 Sturgeon, William (1783–1850), 359, 359f

 Weissenberg, Karl (1893–1976), [547](#), [547f](#)
 Urey, Harold Clayton (1893–1981), [479](#), [479f](#)
 Kramers, Hendrik Anthony (Hans) (1894–1952), [549](#)
 Tamm, Igor (1895–1971), [426](#)
 Sievert, Rolf Maximilian (1896–1966), [310–311](#), [311f](#)
 Tihanyi, Kálmán (1897–1947), [401](#)
 Cockcroft, John (1897–1967), [532](#)
 Knoll, Maximillion (1897–1969), [443](#)
 Krishnan, Kariamianickam Srinivasa (1898–1961), [207](#)
 Wentzel, Gregor (1898–1978), [549](#), [549f](#)
 Smyth, Henry DeWolf (1898–1986), [322](#)
 Rabi, Isidor Isaac (1898–1988), [187–188](#), [188f](#), [433](#)
 Zartman, Ira Forry (1899–1981), [580](#), [580f](#)
 Deshpande, Vijay (mid-twentieth century–), [377](#)
 Jaklevic, Robert C. (mid-twentieth century–), [363](#)
 Lambe, John J. (mid-twentieth century–), [363](#)
 Mercereau, James (mid-twentieth century–), [363](#)
 Silver, Arnold (mid-twentieth century–), [363](#)
 Weir, John B. de V. (?–?, twentieth century), [547](#)
 Kuper, Charles Goethe (twentieth century), [25](#)
 Edwards, Roy Q. (twentieth century–), [315](#)
 Pauli, Wolfgang Ernst (1900–1958), [23](#), [23f](#), [173](#),
 [177](#), [460](#)
 Slater, John C. (1900–1975), [319](#)
 Gagnan, Émile (1900–1979), [288](#)
 Uhlenbeck, George Eugene (1900–1988), [460](#), [460f](#)
 Fermi, Enrico (1901–1954), [398](#)
 Lawrence, Ernest Orlando (1901–1958), [15](#)
 Heisenberg, Werner Karl (1901–1976), [23](#), [148](#), [173](#), [177](#),
 [179](#), [429](#), [472](#)
 Van de Graaff, Robert Jemison (1902–1967), [486](#), [486f](#)
 Goudsmit, Samuel Abraham (1902–1978), [460](#)
 Dirac, Paul Adrien Maurice (1902–1984), [2](#), [23](#), [96](#),
 [173–174](#), [177–178](#), [184](#)
 Wigner, Eugene (Jenő Pál) (1902–1995), [556](#), [556f](#)
 Powell, Cecil Frank (1903–1969), [137](#), [137f](#)
 Wooster, William Alfred (Peter) (1903–1984), [562](#)
 Thomas, Llewellyn Hilleth (1903–1992), [409](#)
 Walton, Ernest Thomas Sinton (1903–1995), [532](#), [532f](#)
 Gamow, Georgiy Antonovich (George) (1904–1968), [179](#)
 Gray, Louis Harold (1905–1965), [565](#)
 Bloch, Felix (1905–1983), [135](#), [433](#)
 Segrè, Emilio Gino (1905–1989), [292](#), [293f](#)
 Anderson, Carl David (1905–1991), [2](#), [178](#)
 Fröhlich, Herbert (1905–1991), [25](#)
 Ruge, Arthur Claude (1905–2000), [355](#)
 Thorndike, Edward M. (1906–?), [413](#)
 Carlson, Chester (1906–1968), [69](#)

- Goeppert-Mayer, Maria (Göppert) (1906–1972), 556
 Tomonaga, Sin-Itiro (朝永 振一郎) (1906–1979), 429, 429f
 Ruska, Ernst (1906–1988), 443
 Bethe, Hans Albrecht (1906–2005), 362
 Womersley, John Ronald (1907–1958), 561, 561f
 Jensen, Johannes Hans Daniel (1907–1973), 556
 Yukawa, Hideki (1907–1981), 576, 576f
 Peierls, Rudolf Ernst, Sir (1907–1995), 25, 25f
 McClung, Fred J. (1907–2014), 168
 Dussik, Karl Theodore (1908–1968), 468
 Landau, Lev Davidovich (1908–1968), 174
 Rytov, Sergei M. [Рытов, Сергей Михайлович] (1908–1996), 258
 Weisskopf, Victor Frederick (1908–2002), 548, 548f
 Land, Edwin Herbert (1909–1991), 117, 449
 Peters, Bernard (1910–1993), 43, 43f
 Plunkett, Roy (1910–1994), 386
 Chandrasekhar, Subrahmanyan (1910–1995), 287
 Cousteau, Jacques-Yves (1910–1997), 288–289
 Hertzprung, Ejnar (1911–1967), 221
 Torrey, Henry Cutler (1911–1998), 433
 Simmons, Edward E., Jr. (1911–2004), 355
 Wheeler, John Archibald (1911–2008), 551–552, 552f
 Hall, Cecil Edwin (1912–1991), 443
 Purcell, Edward Mills (1912–1997), 161, 161f, 433
 Wu, Chien-Shiung (Wú Jiànxiónɡ; 吳健雄) (1912–1997), 564, 564f
 Van Allen, James Alfred (1914–2006), 484–485, 484f
 Townes, Charles Hard (1915–), 278, 439, 439f
 Schiff, Leonard Isaac (1915–1971), 280, 281f
 Hofstadter, Robert (1915–1990), 220
 Wiegand, Clyde (1915–1996), 292
 Hillier, James (1915–2007), 443
 Bascom, William Newell (1916–2000), 448
 Shannon, Claude Elwood (1916–2001), 264, 301–302, 302f
 Prokhorov, Aleksandr M. (1916–2002), 439
 Crick, Francis Harry Compton (1916–2004), 537, 556
 Wilkins, Maurice Hugh Frederick (1916–2004), 537, 556–557, 557f
 Kohman, Truman P. (1916–2010), 11
 Skeggs, Leonard T. Jr. (1918–), 318, 318f
 Feynman, Richard Phillips (1918–1988), 429, 552, 588
 Schwinger, Julian Seymour (1918–1994), 429, 564, 579
 Reines, Frederick (1918–1998), 225–226, 226f
 Pound, Robert Vivian (1919–2010), 135–136, 136f, 433
 Fujita, Tetsuya (1920–1998), 430
 Gould, Gordon (1920–2005), 168
 Chamberlain, Owen (1920–2006), 292
 Rényi, Alfréd (1921–1970), 228, 228f
 Sakharov, Andrei (1921–1989), 426
 Schawlow, Arthur Leonard (1921–1999), 278, 278f
 Yang, Chen Ning (1922–), 569–570
 Basov, Nicolay G. (1922–2001), 439
 Lattes, César Mansueto Giulio (1924–2005), 576
 Perkins, Donald Hill (1925–), 39, 39f
 Tate, John Torrence, Jr. (1925–), 381, 381f
 Van der Meer, Simon (1925–2011), 487, 487f
 Rasmussen, John (1926–), 214, 214f
 Salam, Abdus (1926–1996), 546, 579
 Bilaniuk, Olexa-Myron (1926–2009), 377
 Logan, Benjamin Franklin (1927–), 307
 Perl, Martin Lewis (1927–), 226
 Mills, Robert Laurence (1927–1999), 570
 Watson, James Dewey (1928–), 537, 537f, 556
 Gell-Mann, Murray (1929–), 180, 588
 Kuhl, David Edmund (1929–), 315
 Mössbauer, Rudolf (1929–2011), 220
 Hellwarth, Robert W. (1930–), 168
 Rebka, Glen Anderson, Jr. (1931–), 135–136
 Sudarshan, George (1931–), 377
 Verlet, Loup (1931–), 501
 Prebus, Albert (1931–2000), 443
 Glashow, Sheldon Lee (1932–), 283, 546, 579
 Walecka, John Dirk (1932–), 528, 528f
 Weinberg, Steven (1932–), 546, 546f, 579
 Rubbia, Carlo (1934–), 487
 Shepp, Lawrence (Larry) Alan (1936–2013), 307
 Zweig, George (1937–), 180, 588, 588f
 Tomsett, Michael Francis (1939–), 401
 Josephson, Brian David (1940–), 364
 Brus, Louis E. (1943–), 172
 Ekimov, Alexey (1945–), 172
 't Hooft, Gerard {Geradus} (1946–), 377, 377f
 Georgi III, Howard Mason (1947–), 283
 Schrieffer, Howard Lawrence (1948–), 283–284, 283f
 Bradt, Helmut L. (–1950), 43
 Reed, Mark (1955–), 172

Index of Subjects

Note: Page numbers followed by f refer to figures, respectively.

Acoustics

- Parallel processing, 7
- Parametric acoustic array, 9, 9f
- Paraxial approximation, 10–11, 11f
- Peierls, Rudolf Ernst, Sir (1907–1995), 25, 25f
- Peierls–Fröhlich–Kuper ground state, 25
- Peierls transition, 25
- Period of a cycle (T), 34, 35f
- Periodogram, 37, 37f
- Phantom, 49, 49f
- Phase, 49–50, 50f–51f
- Phase cancellation, 51, 51f
- Phase noise, 53–54, 54f
- Phase rotation, 54, 54f
- Phase sequence, 55
- Phased array, 58, 58f
- Phase velocity, 57
- Phase-only imaging, 58
- Photoacoustic microscopy, 61–64
- Piano, 85–86, 86f
- Piezoelectric effect, 87–88, 88f
- Piezoelectric resonance, 88, 89f
- Piezoelectricity, 89
- Piezoelectric transducer, 89, 89f
- Point source, 111
- Poly(vinylidene) fluoride (PVDF), 122
- Power spectrum, 139
- Praetorius, Michael (original name: Michael Schultheiß) (1571–1621), 140, 140f
- Pyroelectricity, 162
- PZT, 162–163
- Q Factor, 165–166, 166f
- Quantification, 171
- Radiation coupling, 191, 191f
- Radiation force, 192, 192f
- Rayleigh criterion, 215, 215f
- Rayleigh–Sommerfeld diffraction, 218
- Refraction, 225, 225f
- Resonance, 231, 231f

Thermodynamics (*Continued*)

- Schrödinger equation of motion, 285–286, 286f
- Schrödinger Wave Equation, 286
- Second law, 289
- Second law, Kelvin–Planck’s statement, 289
- Second law of Faraday, 290
- Second law of thermodynamics, Carathéodory’s statement of the, 290
- Second law of thermodynamics, Clausius formulation, 290
- Second order phase transition, 290–291, 291f
- Seebeck effect, 292
- Seebeck, Thomas Johann (1770–1831), 292, 292f
- Semipermeable membrane, 299, 299f
- Shannon sampling law, 302
- Shannon sampling theorem, 302
- Shedding frequency (ν_s), 307
- Shell model, 307, 307f
- Solar power, 327–328, 328f
- Solid form of aggregation, 330
- Solidification, 331
- Solid-state, 331
- Solid-state physics, 331
- Solute, 332
- Solution, 332
- Solvent, 333
- Specific heat (c_p), 337
- Spin, 341–342, 342f
- Stirling, Robert (1790–1878), 351, 351f
- Stirling cycle, 351, 351f
- Stoichiometric coefficient, ($\nu_i^{(j)}$), 352
- Stoichiometry, 352
- Stratosphere, 355–356, 356f
- Strong nuclear force, 358, 358f
- Sublimation, 361, 361f
- Subshell, 361
- Supercritical fluid state, 364
- Superheated steam, 365
- Superheated vapor state, 365
- Surface energy, 366–367
- Surface phenomena of Liquids, 367
- Surface Potential Energy, 367–368, 368f
- Surface tension, 370, 370f
- Surfactant, 372, 372f
- Tectonics, 385, 385f
- Temperature (T), 390–391, 391f
- Thermal conductivity, 397
- Thermal diffusivity ($\alpha_{\text{dif}} = \kappa/\rho c_p$), 397
- Thermal energy, 397
- Thermal equilibrium, 397
- Thermal expansion, 397–398, 398f
- Thermal wave, 398–399
- Thermoacoustic imaging, 399
- Thermocouple, 399
- Thermodynamics, 399–400
- Thermodynamics, first law of, 400
- Thermodynamics, second law, 400
- Thermodynamics, third law, 400
- Thermodynamics, zeroth law of, 400
- Thermography, 400–401, 401f
- Thermokinetic oscillator, 402
- Thermometer, 402, 402f
- Thermophysical properties, 404–405
- Thermoscope, 405, 405f
- Thermosphere, 405–406, 406f
- Thermostatics, 406
- Third law of thermodynamics, 408
- Thompson, Benjamin, Sir (1753–1814), 409, 409f
- Thomson, William (1824–1907), 411–412
- Throttle, 415, 415f
- Total potential, 438
- Triple point, 446, 446f
- Troposphere, 448–449, 449f
- Trouton, Frederick Thomas (1863–1922), 449, 449f
- Turbine, 453, 453f
- Ultrahigh pressure, 463
- Uncorrelated states, 473
- Unstable equilibrium state, 476, 476f
- Unsteady state, 478
- Valve, 483–484, 484f
- Van der Waals, Johannes Diderik (1837–1923), 489, 489f
- Van der Waals bonding, 489–490, 490f
- Van der Waals equation of state, 490
- Van Laar equations, 491
- Van’t Hoff equation, 493
- Van’t Hoff factor, 493
- Van’t Hoff, Jacobus Henricus (1852–1911), 493, 493f
- Van’t Hoff law, 494
- Vapor, 494, 494f
- Vapor pressure, 494
- Variance (σ^2), 496, 496f
- Vibration, 502–503, 503f
- Volcano, 514, 514f
- Von Helmholtz, Hermann Ludwig Ferdinand (1821–1894), 518, 518f
- Von Mayer, Julius Robert (1814–1878), 522, 522f
- Vortex, 522–523, 523f
- Vortex shedding, 524
- Water reactor, 534
- Wet-bulb temperature, 550
- Wiedemann–Franz ratio, 554
- Wien, Wilhelm Carl Werner Otto Fritz Franz (1864–1928), 554, 554f
- Wien–Planck law, 554–555, 555f
- Wien’s displacement law, 555, 555f
- XY model, 568
- Young–Laplace equation, 572
- Yukawa, Hideki (1907–1981), 576, 576f
- Yukawa potential, 576–577, 577f
- Zero-entropy state, 585
- Zero-temperature state, 587
- Zeroth law of thermodynamics, 587
